- Other sexually transmitted conditions
- "Syphilis" coined by Fracastoro in 1500s

DIAGNOSTIC TESTS & INTERPRETATION
- "Syphilis" coined by Fracastoro in 1500s

BASICS
- "Syphilis", coined by Fracastoro in 1500s
- Describes infection by the spirochete Treponema pallidum, 1st discovered in 1905 by Hoffman

PATHOPHYSIOLOGY
- Contact inoculation through fluids, in utero; rare dissemination through transfusion
- Incubation: 10–90 days
- "Syphilis", coined by Fracastoro in 1500s

HISTORY
- "Syphilis", coined by Fracastoro in 1500s

DIAGNOSIS
- "Syphilis", coined by Fracastoro in 1500s
- Describes infection by the spirochete Treponema pallidum, 1st discovered in 1905 by Hoffman

PREVENTION
- "Syphilis", coined by Fracastoro in 1500s
- Describes infection by the spirochete Treponema pallidum, 1st discovered in 1905 by Hoffman
SYPHILIS

SURGERY/OTHER PROCEDURES
Acute graft replacement has been used for late syphilitic aortic dissection.

ADDITIONAL TREATMENT

Immunotherapy

Additional Therapies

- Penicillin: 2.4 MU Benzathine PCN G IM q4w
- Azithromycin 1 g PO (single dose)

Ongoing Care

- Excellent in primary syphilis
- Good in asymptomatic neurosyphilis
- Poor if symptomatic tabes dorsalis
- Syphilitic aneurysms can cause death within 6 mo
- Poor if symptomatic tabes dorsalis
- Good in asymptomatic neurosyphilis
- Excellent in primary syphilis

Follow-Up

- Yearly thereafter
- Repeat serologic testing q3mo
- FTA-ABS by 36 mo
- Tuberculin testing
- Check HIV status
- Check CNS/spinal fluid

PEARLS

- Patients with a history of syphilis should be counseled to undergo HIV testing.
- Late syphilis may be asymptomatic.
- Condyloma lata are highly infectious and must be differentiated from HPV-related condyloma acuminate largely on physical exam.

CLINICAL/SURGICAL PEARS

- Screen pregnant women for syphilis (USPSTF grade B recommendation).
- Screen people at-risk for syphilis (USPSTF grade A recommendation).
- Pregnancy is an absolute contraindication for doxycycline or azithromycin.
- Nonpenicillin, Nontetracycline alternatives are inferior to PCN but include ceftriaxone.

CODES

ICD9 - 059.9 Syphilis, unspecified
093.9 Syphilis, unspecified
A51.49 Other secondary syphilitic conditions
59/No. RR-12.

ADDITIONAL READING

REFERENCES

ADDITIONAL MEASURES

- Antimicrobial therapy is maintained.
- Serologic monitoring thereafter
- Contact public health service

MEDICATION

First Line

- Penicillin, 2.4 MU Benzathine PCN G IM × 1 (4)
- PCN-allergy: Tetracycline 500 mg PO q6h or doxycycline 100 mg PO q12h × 2 wk
- If pregnant: Ceftriaxone 1 g IM

Second Line

- Tetracycline 250 mg PO q6h and Doxycycline 100 mg for 14 days
- Azithromycin (Zithromax) 1 g PO × 1

Treatment failure: 4-fold increase in titer
- Treatment is supportive
- Under treatment and development of late disease
- Tabes dorsalis (poor prognosis)
- Aortic aneurysm rupture

FOLLOW-UP

Patient Monitoring

- Repeat serologic testing q6mo × 4 then qmo × 2
- Yearly thereafter
- 4-fold decrease should be seen in 12–24 mo
- Treatment failure: 4-fold increase in titer

Patient Resources

**TESTIS CANCER, ADULT GENERAL CONSIDERATIONS**

Brett S. Carver, MD

**BASICS**

**DESCRIPTION**
- Testicular cancer is a malignancy of germ cell origin originating in the testis and is the most common malignancy in males, 15–35 yr of age.
- Testicular cancer may always be considered in males presenting with testicular swelling.
- Patients with testicular cancer may present with a testicular mass, gynaecomastia, infertility, abdominal mass, or symptoms related to metastatic disease such as back pain or cough.

**EPIDEMIOLOGY**

**Incidence**
- It is estimated that in US, 8,820 new cases of testicular cancer would be diagnosed and 380 men would die of this disease in 2014.
- Germ cell tumors (GCTs) of the testis occur predominantly in Caucasian males.
- Lifetime risk of developing testis cancer is ~1 in 270, and the lifetime risk of dying of testicular cancer is ~1 in 5,000.

**Prevalence**

**RISK FACTORS**
- Risk factors associated with the development of testicular cancer:
  - Cryptorchidism
  - Family history of testicular cancer or other malignancies
  - Testicular atrophy
  - Klinefelter syndrome
  - Cannabinoid use controversy

**Genetics**
- Identification of isochromosome 12p amplification.

**PATHOPHYSIOLOGY (1)**
- GCTs of the testis can be divided into 2 major subgroups based on histology: Seminoma and nonseminomatous germ cell tumor (NSGCT).
  - Seminoma: ~50% of all testicular cancers most frequently appear in the 4th decade of life.
  - ~10–15% of patients will produce the serum tumor marker human chorionic gonadotropin (HCG).
  - The remainder of GCTs is comprised of nonseminomatous histology (embryonal carcinoma, yolk sac tumor, choriocarcinoma, and teratoma) and frequently present in the 3rd decade of life.
  - ~50–70% of nonseminomas will produce α-fetoprotein (AFP) and/or HCG.

**Histologic findings of seminoma, embryonal carcinoma, choriocarcinoma, yolk sac tumor, teratoma.**

**ALERT**
- Markers must be drawn prior to radical orchiectomy.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Serum tumor markers (AFP, HCG) should be obtained prior to orchiectomy.
- The serum tumor markers are necessary for diagnosis, staging, and risk classification.
- Tumor markers obtained prior to orchiectomy:
  - 1 or more elevated in 85–90% of NSGCT
  - HCG:
    - Half-life: 24–36 hr
    - Elevated in 40–60% with testis cancer; 100% of choriocarcinomas
  - AFP:
    - Half-life: 5–7 days
    - Produced by yolk sac tumors, embryonal cell carcinoma, and teratocarcinomas
    - Not produced in pure seminoma or pure choriocarcinoma
  - If AFP elevated in case of pure seminoma, NSGCT elements are present.

**Associated Conditions**
- Infertility
- Cryptorchidism
- Gynaecomastia

**GENERAL PREVENTION**
- Possible early orchiectomy for undescended testicle
- USPSTF: Against routine screening for testicular cancer in asymptomatic adolescent and adults including routine testicular self-exams.
- American Cancer Society suggests that men with family history do monthly self-exams.

**DIAGNOSIS**

**HISTORY**
- The most common symptom at the time of diagnosis is painless swelling or enlargement of the testis.
- Acute testicular pain is reported to occur in ~10% of patients with testicular cancer and often represents infarction or hemorrhage within the tumor.
- At initial presentation, symptoms manifesting secondary to metastatic disease occur in ~20% of patients and include:
  - A mass in the left neck, pulmonary complaints such as hemoptysis or dyspnea, an abdominal mass, or back pain that can often be disabling.
  - In ~5% of patients, gynaecomastia or tenderness of the breast is reported.

**PHYSICAL EXAM**
- The most common finding on physical exam is a solid intratesticular mass or swelling.
- Patients should undergo a complete physical exam with emphasis on palpation of the cervical lymph nodes (lymphadenopathy), breasts (gynecomastia), abdomen (lymphadenopathy, liver masses), and the contralateral testis (bilaterally testicular tumors).

**ALERT**
- Baseline ultrasonography is the initial imaging modality of choice with a ~95% specificity in identifying intratesticular lesions.
- Testicular ultrasonography often reveals a solid hypoechoic mass present within the testis.
- The contralateral testis should also be imaged as ~2% of patients will have bilateral testicular cancers.
- The initial staging evaluation should include a CT scan of the chest, abdomen, and pelvis with and without contrast.
- CT is the most effective radiographic technique for identifying metastatic disease both above and below the diaphragm.
- No evidence of metastases in ~70% of patients with seminoma and 35% of patients with nonseminoma.

**Diagnostic Procedures/Surgery**
- A radical orchietomy with high ligation of the spermatic cord at the level of the inguinal ring provides histopathologic diagnosis, primary tumor staging, and excellent local control of the tumor, with minimal morbidity and no mortality.

**Pathologic Findings**
- Histologic findings of seminoma, embryonal carcinoma, choriocarcinoma, yolk sac tumor, teratoma.
- Documentation of lymphovascular invasion.
- Pathologic and clinical staging follows the TNM classification and risk assessment if performed using the International Germ Cell Cancer Collaborative Group (IGCCCG) risk classification.

**ALERT**
- 18–33% of patients with testicular cancer were initially treated for epididymitis resulting in a delay in diagnosis of testicular cancer.
DIFFERENTIAL DIAGNOSIS

- Benign lesions
  - Epididymitis/orchitis
  - Bacterial, STD, mumps
  - Testicular trauma: Usually blunt; contusion, rupture, usually associated hematoma
  - Torsion (testicle or appendix)
  - Intratesticular neuroepithelial hamartoma
  - Cysts (simple, tubular, albino, epidemoid)
  - Adrenal rest tumors: In general benign, but can contribute to infertility in patients with congenital adrenal hyperplasia.
  - Fibrous pseudotumor of the testis/epididymis
  - Parakeratinized squamous metaplasia
  - Eosinophilic granuloma
  - Malignant lesions
    - Testicular primary tumors (GCT, stromal and mixed as discussed above)
    - Leukemia involving testis: Tests can be a site of solitary recurrence of leukemic postmortem (sanitary site). Biopsy to confirm diagnosis. Treat with testis-sparing radiation, treat bilaterally.
    - Symptoms involving testis: Usually represents extension from extratesticular sites, rarely can represent a primary (lymphoma 1% of lymphoma cases). Can present bilaterally one-third of the time; mostly involves older men >60 yrs; constitutional symptoms common present (fever, chills, night sweats, weight loss).
    - Metastatic solid tumors: Common: Prostate, lung, GI tract; more rare: Kidney, malignant melanoma, parotid, bladder, and thyroid.
    - Adenocarcinoma of the testis: Arises in the testis collecting system, high-stage presentation, poor response to chemotherapy and radiation, with median survival of 1 yr.
    - Mesothelioma of testicle/vaginalia: Rare, similar to the more common pleural histology, associated with asbestos exposure.
    - Paratesticular sarcomas: Rhabdomyosarcoma, malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life).

TREATMENT

GENERAL MEASURES

- Inguinal radical orchiectomy/high ligation of the spermatic cord is diagnostic and therapeutic.
- Patients are then staged based on TNM classification (see Section VII: “Reference tables: TNM. Testis Cancer”).

ALERT

Discuss sperm banking prior to treatment.

MEDICATION

First Line (1,2)

- Regardless of histology, patients with advanced GCTs (III–IV) and with persistently elevated tumor markers following radical orchiectomy (UII), are initially treated with platinum-based chemotherapy according to the IGCCCG risk stratification.
  - Good-risk disease: 3 cycles of bleomycin, etoposide, and cisplatin (BEP) or 4 cycles of etoposide and cisplatin (EP).
  - Intermediate-risk or high-risk disease: 4 cycles of BEP — 10–40% of patients with poor-risk disease fail to achieve a durable response to conventional chemotherapy

Second Line

Second-line chemotherapeutic regimens are reserved for advanced testicular cancer in whom serum tumor markers do not normalize following initial therapy.

SURGERY/OTHER PROCEDURES

- Radical orchiectomy should be performed for diagnostic and treatment of the primary tumor.
- In US, the preferred management for patients at high risk for relapse in the retroperitoneum, ie, placental site primary carcinoma, lymphovascular invasion, or extension into the tunica or scrotum, is primary RPLND if serum tumor markers have normalized.
- Postchemotherapy RPLND (PC-RPLND) and resection of residual masses should be done. Following chemo, 40% undergoing RPLND will have teratoma; 10–15% have GCT.

ADDITIONAL TREATMENT

Radiation Therapy

In US, radiation therapy to the retroperitoneum remains the treatment of choice for patients with clinical stage I and IIa seminoma.

Additional Therapies

- Surveillance, with serial imaging and tumor markers, in well-selected low-risk patients.
- Stage I seminoma:
  - Stage I NSGCT:
  - No teratomatous elements, no lymphovascular invasion, and no embryonal cell carcinoma in the primary specimen. Patients must be reliable

Complementary & Alternative Therapies

Discuss sperm banking before therapy.

ONGOING CARE

PROGNOSIS

- Prognosis is dependent on initial clinical stage, risk stratification, and histology.
- The multidisciplinary approach to GCT has survival rates at >90%.

COMPLICATIONS

- Radical orchiectomy: Wound infection, scrotal and/or retroperitoneal hematoma
- RPLND: Wound infection, parapneumonic, venous thrombosis, chylous ascites, anejaculation, and small-bowel obstruction.
- Chemotherapy: Neutropenia, gastrointestinal symptoms, alopecia, pulmonary fibrosis, and cardiovascular events.

FOLLOW-UP

Patient Monitoring

Physical and/or chest CT imaging of the chest, abdomen, and pelvis is needed follow-up according NCCN guidelines.

Patient Resources

CODES

ICD9

- 186.9 Malignant neoplasm of unspecified testes
- 185.9 Malignant neoplasm of other and unspecified testes
- 608.3 Atrophy of testis

ICD10

- C69.0 Malignant neoplasm of unspecified testis
- C69.9 Malignant neoplasm of unspecified testes
- K00.0 Atrophy of testis

CLINICAL/SURGICAL PEARLS

All intrascrotal masses should be assumed to be testicular cancer until proven otherwise.

Elevated AFP is diagnostic for nonseminomatous GCT.

Inguinal radical orchiectomy with high ligation of the spermatic cord is the initial treatment.
TESTIS CANCER, CHORIOCARCINOMA
Brett S. Carver, MD

BASICS

DESCRIPTION
- Choriocarcinoma is a type of germ cell tumor (GCT) composed of syncytiotrophoblastic, cytotrophoblastic, and other trophoblastic cells.
- Histologic cell type for nonseminomatous GCTs.
- Pure choriocarcinomas are commonly associated with metastatic disease and high levels of hCG at the time of presentation.

EPIDEMIOLOGY

Incidence
- It is projected that in US, 8,820 new cases of testicular cancer would be diagnosed and 380 men would die of this disease in 2014.
- Pure choriocarcinoma comprises <1% of testicular GCT.
- Choriocarcinoma is a histologic cell type in ~10% of nonseminomas.

Prevalence

N/A

RISK FACTORS

- Risk factors associated with the development of testicular cancer include:
  - Cryptorchidism, family history, testicular atrophy, infertility.

Genetics

Identification of isochromosome 12p amplification.

PATHOPHYSIOLOGY

- Choriocarcinoma is a histologic subtype of nonseminomatous GCTs composed primarily of syncytiotrophoblastic and cytotrophoblastic.
- Syncytiotrophoblastic cells produce human chorionic gonadotropin (HCG) which may be detected by endocrinology or measurement of serum levels.
- Pure choriocarcinomas are associated with significantly elevated levels of serum HCG. Choriocarcinoma represents a germ cell transformed through extraembryonic differentiation.
- Relationship between size of primary tumor and metastatic disease may seem paradoxical, with widespread disease associated with a relatively small primary tumor.
- Route of metastatic spread is variable compared to other GCTs, which are often stepwise and widespread.
- Choriocarcinoma is associated with a greater propensity for hematogenous dissemination.
- hCG is produced by syncytiotrophoblasts and is elevated in 100% of choriocarcinomas. The serum half-life of hCG is 24–36 h.
- Elevated serum levels of hCG are also noted in 40–60% of embryonal carcinomas and 5–10% of pure seminomas.

ASSOCIATED CONDITIONS

- Infertility
- Cryptorchidism
- Gynecomastia

GENERAL PREVENTION

- Conflicting data; early orchectomy reduces testis cancer risk in cryptorchidism

DIAGNOSIS

HISTORY

- Past medical history focusing on history of cryptorchidism.
- The most common symptom at the time of diagnosis is painless swelling or enlargement of the testis. Acute testicular pain is reported to occur in ~10% of patients with testicular cancer and often represents infection or hemorrhage within the tumor.
- At initial presentation, symptoms manifesting secondary to metastatic disease occur in ~20% of patients and include, a mass in the left neck, pulmonary complaints such as hemoptysis or dyspnea, an abdominal mass, or back pain that can often be disabling.
- Patients with choriocarcinoma may present with gynecomastia or tenderness of the breast secondary to elevated serum HCG.
- Neurologic symptoms related to brain metastases may be present in patients with advanced pure choriocarcinoma.

PHYSICAL EXAM

- The most common finding on physical exam is a solid intratesticular mass or swelling.
- Through exam of both groins — Careful palpation of surrounding spermatic cord structures on involved side to evaluate extent of disease.
- Transillumination of scrotal contents if hydrocele is present.
- Cervical lymph nodes (lymphadenopathy), breasts masses/lymphadenopathy, liver masses.
- Histologic cell type for nonseminomatous GCTs composed primarily of syncytiotrophoblastic, cytotrophoblastic, and other trophoblastic cells.
- Histologic cell type for nonseminomatous GCTs.
- Pure choriocarcinomas are commonly associated with metastatic disease and high levels of hCG at the time of presentation.
- Identification of isochromosome 12p amplification.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Serum tumor markers (AFP, HCG, LDH) should be obtained prior to and following radical orchectomy. The serum tumor markers are necessary for diagnosis, staging, and risk classification. While normal postorchectomy serum tumor markers does not preclude the finding of metastatic disease, an elevation of either AFP or HCG does signify the presence of metastases.
- Pure choriocarcinomas are often associated with significantly high levels of serum HCG.

PHYSICAL EXAM

- The most common finding on physical exam is a solid intratesticular mass or swelling.
- Through exam of both groins — Careful palpation of surrounding spermatic cord structures on involved side to evaluate extent of disease.
- Transillumination of scrotal contents if hydrocele is present.
- Cervical lymph nodes (lymphadenopathy), breasts masses/lymphadenopathy, liver masses.
- Histologic cell type for nonseminomatous GCTs composed primarily of syncytiotrophoblastic, cytotrophoblastic, and other trophoblastic cells.
- Histologic cell type for nonseminomatous GCTs.
- Pure choriocarcinomas are commonly associated with metastatic disease and high levels of hCG at the time of presentation.
- Identification of isochromosome 12p amplification.

DIFFERENTIAL DIAGNOSIS

- There are a delimitation of testicular masses only. For a complete listing of intrascrotal and testicular masses see Section I: “Scrotum and Testicle Mass:”
- Benign lesions:
  - Epididymitis/Orchitis: Bacterial, STD, mumps, TB
  - Testicular trauma: Usually blunt; contusion, hematoma
- Neoplasm:
- Testicular: Various, with seminoma, embryonal carcinoma.
- Adnexal masses:
- Fallopian tube: Benign, malignant

- Pure choriocarcinomas are often associated with significantly high levels of serum HCG.

IMAGING

- Testicular ultrasonography is the initial imaging modality of choice with a >95% sensitivity and specificity in identifying intratesticular lesions.
- Testicular ultrasonography often reveals a solid hypoechoic mass present within the testis.
First Line (2)

TREATMENT

GENERAL MEASURES (1)

- Treatment options are based on clinical staging.

- Prognosis for patients with testicular cancer is based on physical exam, serum tumor markers, and histologic tumor features according to the TNMS staging system.

MEDICATION

First Line (2)

- Bilateral disease can be present. Though contralateral testis should be treated as a potential sanctuary site. Biopsy can be utilized to confirm diagnosis of the primary tumor.

- All intratesticular masses should be assumed to be testicular cancer until proven otherwise.

- All intratesticular masses should be assumed to be testicular cancer until proven otherwise.

- Malignant lesions: Testicular primary tumors (carcinoma and nonseminomatous GCTs) grow in the spermatic cord and are diagnostic and therapeutic.

- Adenocarcinoma of the rete testis: Arises in the mediastinum and is characterized by constitutional symptoms commonly present (fever, chills, night sweats, weight loss).

- Lymphoma involving testis—usually represents a systemic process and is often characterized by a high burden of disease or poor prognosis.

- Leukemia involving testis—testis can be a site of disease relapse and is often a site of initial failure.

- Poor prognosis: Mediastinal primary, nonseminomatous visceral metastases, AFP > 1,000, β-hCG > 5,000, and LDH > 1.5 for upper limit of normal (ULN)

- Intermediate prognosis: Testis or retroperitoneal primary, no nonpulmonary visceral metastases, AFP 1,000–10,000, β-hCG 5,000–50,000, or LDH 1.5–10 ULN

- Good prognosis: Testicular primary, nonseminomatous visceral metastases, AFP > 10,000, β-hCG > 50,000, and LDH ≤ 10 ULN

- Complications of chemotherapy: Neutropenia, gastrointestinal symptoms, alopecia, pulmonary fibrosis, and cardiovascular events; propensity for gastrointestinal symptoms, alopecia, pulmonary fibrosis.

- Complications of RPLND: Wound infection, scrotal hematoma, and retroperitoneal hematoma.

- Choriocarcinoma is often associated with hemoptysis, neurologic and pulmonary monitoring is critical following chemotherapy.

- Second Line chemotherapy is reserved for patients with advanced testicular cancer in whom serum tumor markers do not normalize following initial chemotherapy regimen.

SURGERY/OTHER PROCEDURES

- Radical orchiectomy is performed for diagnosis and treatment of the primary tumor.

- In US, the preferred management for patients at high risk for relapse in the retroperitoneum, ie, predominant embryonal carcinoma, lymphocytic invasion, or extension into the tunica or scrotum, is primary RPLND if serum tumor markers have normalized.

- Postchemotherapy RPLND (PC-RPLND) and resection of residual masses are an integral component in the management of advanced nonseminoma.

ADDITIONAL TREATMENT

Radiation Therapy

Occasionally radiation therapy for cerebral metastases is utilized, but systemic therapy remains the initial treatment of choice for the management of metastatic disease including cerebral metastases.

Additional Therapies

- Complementary & Alternative Therapies

ONGOING CARE

CLINICAL/SURGICAL PEARLS

- All intratesticular masses should be assumed to be testicular cancer until proven otherwise.

- Choriocarcinomas are associated with production of β-hCG.

- Choriocarcinomas have a predilection for brain metastases.

- Inguinal radical orchiectomy with high ligation of the spermatic cord is diagnostic and therapeutic.

- Treatment options are based on clinical staging, through contralateral testis should be treated as a potential sanctuary site.

- Lymphoma involving testis—usually represents a systemic process and is often characterized by a high burden of disease or poor prognosis.

- Leukemia involving testis—testis can be a site of disease relapse and is often a site of initial failure.
TESTIS CANCER, EMBRYONAL CARCINOMA

ASSOCIATED CONDITIONS
• Infertility
• Cryptorchidism
• Seminoma

GENERAL PREVENTION
• Possibility early orchectomy for undescended testicle
• Textile self-exam

DIAGNOSIS
• Signs and symptoms
  • Painless testicular mass (50–60%)
  • Testicular pain or dull ache (30–40%)
  • Painless testicular mass (50–60%)
  • Testicular pain or dull ache (30–40%)
  • Testicular self-exam

PHYSICAL EXAM
• Signs and symptoms
  • Pale or vacuolated cytoplasm
  • Epithelioid cells arranged in glands or tubules,

DIAGNOSTIC TESTS & INTERPRETATION
• Tumor markers
  • AFP (alpha fetoprotein)
  • HCG (human chorionic gonadotropin)

PATHOPHYSIOLOGY
• EC is an aggressive GCT subtype
• High associated relapse rate (35–40%)
• Absent in pure seminoma and choriocarcinoma.
• Human chorionic gonadotropin (HCG)
• Normally secreted by placental syncytiotrophoblasts.
• Half-life of ~24–36 hr. Consists of α- and β-chains; α-chain analogous to hCG.

DIAGNOSTIC TESTS & INTERPRETATION

• Human chorionic gonadotropin (HCG)
• Normally secreted by placental syncytiotrophoblasts.
• Half-life of ~24–36 hr. Consists of α- and β-chains; α-chain analogous to hCG.
• Elevated in 60% of all GCT, 90% of seminomas, and all choriocarcinomas.

DIAGNOSTIC TESTS & INTERPRETATION
• Lab
  • Alpha fetoprotein (AFP)
  • β-HCG
  • Scrotal ultrasound (US) (see “Imaging”)
  • Transillumination test

PHYSICAL EXAM
• Signs and symptoms
  • Painless testicular mass (50–60%)
  • Testicular pain or dull ache (30–40%)
  • Painless testicular mass (50–60%)
  • Testicular pain or dull ache (30–40%)
  • Testicular self-exam

DIAGNOSTIC TESTS & INTERPRETATION
• Tumor markers
  • AFP (alpha fetoprotein)
  • HCG (human chorionic gonadotropin)

PATHOPHYSIOLOGY
• EC is an aggressive GCT subtype
• High associated relapse rate (35–40%)
• Absent in pure seminoma and choriocarcinoma.
• Human chorionic gonadotropin (HCG)
• Normally secreted by placental syncytiotrophoblasts.
• Half-life of ~24–36 hr. Consists of α- and β-chains; α-chain analogous to hCG.
• Elevated in 60% of all GCT, 90% of seminomas, and all choriocarcinomas.
• Lactate dehydrogenase (LDH)
• Normally secreted by placental syncytiotrophoblasts.
• Half-life of ~24–36 hr. Consists of α- and β-chains; α-chain analogous to hCG.
• Elevated in 60% of all GCT, 90% of seminomas, and all choriocarcinomas.
• Lactate dehydrogenase (LDH)
• Normally secreted by placental syncytiotrophoblasts.
• Half-life of ~24–36 hr. Consists of α- and β-chains; α-chain analogous to hCG.
TESTIS CANCER, EMBRYONAL CARCINOMA

ADDITIONAL READING

5. NCCN follow-up protocol:

   Patient Monitoring
   — Primary surveillance:
   — 20% recurrence, most common 1st 2 yr
   — NCCN follow-up protocol:
     Year 1: Tumor markers and chest x-ray every 1–2 mo; abdominal CT every 3–4 mo
     Year 2: Tumor markers and chest x-ray every 2 mo; abdominal CT every 4–6 mo
     Years 3–5: Tumor markers and chest x-ray every 3–6 mo; abdominal CT every 6–12 mo
     After year 5: Tumor markers and chest x-ray every 1–2 yr
   — RPLND:
     Most likely site of recurrence is the chest (3)
     — NCCN follow-up protocol:
       Year 1: Tumor markers and chest x-ray every 2–3 mo; baseline abdominal/pelvic CT
       Year 2: Tumor markers and chest x-ray every 2–3 mo; abdominal/pelvic CT as indicated
       Year 3–5: Tumor markers and chest x-ray every 3–12 mo; abdominal/pelvic CT as indicated
       After year 5: Tumor markers and chest x-ray every 3 yr
   — Chemotherapy and RPLND:
     — NCCN follow-up protocol:
       Year 1: Tumor markers and chest x-ray every 2–3 mo; abdominal/pelvic CT every 6 mo
       Year 2: Tumor markers and chest x-ray every 2–3 mo; abdominal/pelvic CT every 6–12 mo
       Years 3–5: Tumor markers and chest x-ray every 3–12 mo; abdominal/pelvic CT as indicated
       After year 5: Tumor markers and chest x-ray every 3 yr

CODES

ICD9
491.9 Malignant neoplasm of other and unspecified tests
608.3 Atrophy of tests
752.51 Undescended tests
ICD10
C62.90 Malig neoplasm of unsp testis, unsp
carcinoma of the testis
Q53.9 Undescended testicle, unspecified
descended or undescended
Q539.9 Undescended testicle, unspecified
descended or undescended
608.3 Atrophy of tests
752.51 Undescended tests

CLINICAL/SURGICAL PEARLS

1. No evidence testicular mass is testicular cancer until proven otherwise.

2. Transrectal or biopsy is contraindicated.

3. EC is aggressive histologic subtype with increased risk of occult disease.

4. Second opinion of pathologic specimens by experienced pathologists is encouraged.

TESTIS CANCER, ENDODERMAL SINUS TUMORS (YOLK SAC TUMORS)

Elizabeth V. Dray, MD
Marcus L. Quek, MD, FACS

PATHOPHYSIOLOGY
- Associated with gains in chromosome 12p in adults.
- RUX1 promoter methylation on chromosome 1p in children (1)
- ITGCN precursor lesion in adults, unclear relationship in children.
- Lymphatic and hematogenous spread
- Up to 20% of children present with large metastases compared to 4–6% of adults

ASSOCIATED CONDITIONS
- Adults:
  - Cryptorchidism
  - Later age at orchiopexy associated with higher relative risk of cancer
  - Risk also increases with intra-abdominal testis and bilateral cryptorchidism.
- Children:
  - Disorders of sex development

DIAGNOSIS
- Presents as painless testicular mass
- May also present as retroperitoneal mass in mediastinal GCT
- Incidentally associated with trauma in <10% of cases.

PHYSICAL EXAM
- Painless testicular mass
- 15–50% have associated hydrocele

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum tumor markers
  - HCG never elevated in pure YST.
  - Tumor markers elevated after appropriate half-life decline.

Imaging
- Sonob US
  - Hepaticor or heterogenous mass with increased blood flow on Doppler

CT
- Stains positive for AFP

Differential Diagnosis
- Adenomatous tumor of testis or epididymis
- Adrenal rest tumors
- Cystic dysplasia of the testis
- Chylous cyst of the mediastinum
- Henoch–Schönlein purpura (usually no mass)

Diagnosis
- Precision of testis-sparing surgery.

Etiology
- In children, anechoic cystic lesions with blood flow on Doppler
- Normal AFP suggestive of benign mass, can attempt testis-sparing surgery.
- CT chest/abdomen/pelvis with PO and IV contrast
- For staging in all age groups.

Genetics
- Heredity unknown

Risk Factors
- General risk for testicular cancer
  - Cryptorchidism
  - Klinefelter syndrome
  - Family History
  - Male infertility
  - Loss of body hair, young maternal age
  - Young paternal age
  - Testicular microcystis

Heredity
- Unknown

RISK FACTORS
- N/A

Prevalence
- 85% of children present with stage I disease, compared to 20% of postpuberal cases

Epidemiology
- Incidence
  - Children:
    - Incidence of pediatric testis tumors is 0.3–1.2 per 100,000
    - YST comprised 62% of all testicular tumors in childhood based on AAP tumor registry.
  - Adults:
    - In US, ~8,820 new cases of testicular cancer would be diagnosed and 380 men would die of this disease in 2014.
    - Lifetime risk of developing testis cancer is ~1 in 270, and the lifetime risk of dying of testicular cancer in US is ~0.003.
    - Pure YST is extremely rare, but found in 4% of mixed GCTs.

Diagnosis
- Presents as painless testicular mass
- May also present as retroperitoneal mass in mediastinal GCT
- Incidentally associated with trauma in <10% of cases.

History
- Presents as painless testicular mass
- May also present as retroperitoneal mass in mediastinal GCT
- Incidentally associated with trauma in <10% of cases.

Differential Diagnosis
- Scrotal edema (insect bite, nephrotic syndrome, acute idiopathic scrotal edema)
- Spina bifida epidermal cyst
- Testicular cysts
- Testicular tumors:
  - YST, teratoma, seminoma, embryonal, choriocarcinoma, mixed tumors
  - Gonadal stromal tumors: Leydig tumor, Sertoli cell, granulosa cell tumors
- Metastatic tumors
  - Mesothelial tumors
  - Hamartoma, carcinoid, and neurofibroma
  - Testis tumor of adrenogenital syndrome
  - Leukemia or lymphoma
  - Yolk sac

Pathologic Findings
- Gross:
  - Endodermal sinus tumors appear firm, yellow-white mass
- Microscopic:
  - Round to oval cells of atoll, yolk sac, mesenchyme
  - Arranged in glandular, papillary, or microcystic pattern with hyaline globules
  - Schiller–Duck bodies characteristic finding
  - Stains positive for AFP

TESTIS CANCER, ENDODERMAL SINUS TUMORS (YOLK SAC TUMORS)

TREATMENT

GENERAL MEASURES

- Adults:
  - Management handled as for nonseminomatous GCT. See Section I “Testis Cancer: Nonseminomatous Germ Cell Tumors, General.”

- Children:
  - Inguinal orchiectomy curative in 80% of children with stage I disease.
  - Adjuvant chemotherapy recommended for stage II–IV disease.

MEDICATION

First Line (4)

- Chemotherapy: Bleomycin, etoposide, cisplatin (BEP)
  - Carboplatin may have equivalent outcomes compared to cisplatin with decreased ototoxicity and nephrotoxicity.

Second Line

- Etoposide, ifosfamide, cisplatin (VIP)
  - High-dose chemotherapy regimens for treatment failures.

SURGERY/OTHER PROCEDURES

- In children: Lymph nodes >2 cm and <4 cm in size at diagnosis should undergo excisional or interventional radiology biopsy to confirm histology.

- Postchemotherapy residual retroperitoneal disease should undergo retroperitoneal lymphadenectomy.

ADDITIONAL TREATMENT

Radiation Therapy

No role for radiation in endodermal sinus tumor.

Additional Therapies

- Sperm banking should be offered prior to chemotherapy in adolescents and adults.

- Fertility-sparing procedure for prepubertal boys are controversial, but include Testicular sperm extraction (TESE) and cryopreservation of testicular tissue.

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Adults: See “NSGCT”

- Children:
  - Survival for all stages approaches 100% at 6 yr.
  - 20% of children with stage I disease will relapse during surveillance; however, excellent cure rates with chemotherapy.

COMPLICATIONS

- Chemotherapy toxicity
  - Bleomycin: Pulmonary fibrosis
  - Carboplatin: Ototoxicity, nephrotoxicity, neuropathy
  - Etoposide: Panostytopenia
  - Infertility

FOLLOW-UP

Patient Monitoring

- Children:
  - CXR, CT or MR, AFP, and history and physical exam monthly for 3 mo, then at 6 mo postoperatively, and subsequently every 6 mo for 36 mo.

- Note: Imaging guidelines evolving in light of increasing awareness of the impact of radiation on pediatric populations.

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis.
- 608.89 Other specified disorders of male genital organs
- 752.9 Undescended testicle, unspecified

ICD10

- C62.90 Malignant neoplasm of unspecified testis
- C62.89 Other specified disorders of male genital organs
- N50.8 Other specified disorders of male genital organs
- Q53.9 Undescended testicle, unspecified

CLINICAL/SURGICAL PEARLS

- Endodermal sinus tumor is the most common GCT of the epididymis.
- Inguinal orchectomy with high ligation of spermatic cord maintains therapy.
- Excellent prognosis for all stages in children.
## Testis Cancer, Nonseminomatous Germ Cell Tumors, General

Robert H. Blackwell, MD
Marcus L. Quek, MD, FACS

### BASICS

**DESCRIPTION**
- Nonseminomatous germ cell tumors (NSGCTs) are malignant neoplasms of the testicle originating from germ cells, excluding seminoma.
- 4 histologic types: Choriocarcinoma, embryonal cell, teratoma, and yolk sac.
- ~50% of NSGCT have a mixed histology, may also include a seminoma component (mixed GCT).

**RISK FACTORS**
- **Cryptorchidism:** ~7–10% incidence in cryptorchid patients in the US (8,820 new cases will be diagnosed with about 370 deaths).
- **SEER age-adjusted incidence of testicular cancer in US in 2010 was 221,020.**

**EPIDEMIOLOGY**

- **Incidence**
  - SEER prevalence of testicular cancer in US in 2010 was 221,020.
  - In US (2014), ~8,800 new cases will be diagnosed with about 370 deaths.

- **Prevalence**
  - SEER prevalence of testicular cancer in US in 2010 was 221,020.

### RISK FACTORS

- **Family history:** ~1–4% of patients with newly diagnosed GCTs report a family history.
- Sons have a 4–6× increased risk of GCT, siblings have a 5–10× increased risk.

**Cryptorchidism:** ~3–7× increased risk of GCT.
- 3–10% incidence in cryptorchid patients in the ipsilateral undescended testicle, ~5% in the contralateral testicle.

**Environment:** Higher incidence in Northern Europe (8–10×).
- 5% in the Americas, Africa, Asia.

**Prior testicular tumor:** 2% incidence of malignancy.
- 7–10% incidence in cryptorchid patients in the US.

**Family history:**
- ~30–40% of testicular tumors in men with a family history do monthly self-exams.
- Sons have a 4–6× increased risk of GCT; siblings have a 5–10× increased risk of GCT.

**Genetics**
- Identification of isochromosome 12p amplification; found in nearly all GCT.
- 2–3% incidence of bilateral testis tumors may suggest congenital predisposition.

### PATOPHYSIOLOGY

- **ITGCN (Intestinal-type germ cell neoplasia also referred to as CT) is believed to be the precursor lesion of all GCTs, excluding spermatocytic seminoma.**
- ~25% of patients with a GCT will have ITGCN in the contralateral testicle.

- **GCTs typically spread in a predictable manner** via the retroperitoneal (lymph nodes although choriocarcinoma also spreads hematogenously):
  - Right-sided tumors typically spread to retroperitoneal lymph nodes. Tumor may spread right to left, but not left to right.
  - Right-to-left spread of choriocarcinoma via the thoracic duct, and left-sided tumors (usually left) retrograde to the contralateral lymph nodes.
  - Nerve 60% of NSGCT contain ~1 histologic subtype in varying amounts (mixed GCT).

### CHORIOCARCINOMA

- **Expected presenting age:** 20–30 yr
- **Tumor markers:** Markedly elevated HCG, normal AFP.
- **Radiotherapy** may be effective for small tumors.

### EMBRYONAL CELL CARCINOMA

- **Expected presenting age:** 25–35 yr
- **Tumor markers:** Elevated or normal HCG/AFP.
- **ITGCN:** 70% progresses to GCT over 7 yr.

### TERAATOMA

- **Expected presenting age:** 0–10 yr
- **Tumor markers:** Markedly elevated AFP, normal HCG.

### YOLK SAC TUMOR

- **Expected presenting age:** 0–10 yr
- **Absence of yolk sac elements in mixed GCT is a predictor of worse outcome.**

### ASSOCIATED CONDITIONS

- **Choriocarcinoma**
  - Presents as painless mass or swelling testicle.
  - May be initially detected following testicular trauma, but not associated with trauma.
  - **Back or flank pain present in ~10% of cases.**

### PHYSICAL EXAM

- **Scrotal exam including both testes, epididymis, and scrotal contents.**
- **Abdominal exam with attention to palpable lymphadenopathy and/or viscer.**
- **Spermatic/epididymal**
- **Gynecomastia** (present in ~7%).

### DIAGNOSTIC TESTS & INTERPRETATION

**Lab**
- **Tumor markers:** Used preop, postop, surveillance.
  - **HCG:** Produced by syncytiotrophoblasts.
  - **AFP:** Produced by epithelial lining of endodermal sinus.
- **Half-life:** 5–7 days.
- **LDH:** Elevated with increased tumor burden.
- **Half-life:** 4–5 days.

**Imaging**
- **Scrotal US:** Tumors tend to be hypochogenic with blood flow seen within the tumor.
- **Microthorax:** Prevalence of <6% in patients undergoing testicular ultrasound, although controversial if associated with malignancy.

### Histopathology

- **Choriocarcinoma:** Have both syncytiotrophoblasts and endodermal sinus.
- **Embryonal:** Distinct cell arrangements and vascular invasion often present.
- **Teratoma:** At least 2 germ cell layers present.
- **Yolk sac:** May be intra-abdominal, pelvic, or mesenteric.
- **AFP:** Produced by epithelial lining of endodermal sinus.
- **Half-life:** 24–36 hr.
- **HCG:** Produced by syncytiotrophoblasts.
- **Half-life:** 5–7 days.

### DIFFERENTIAL DIAGNOSIS

- See Section I “Testis Cancer, Adult General Considerations” and “Testis Cancer, Pediatric, General Considerations.”

### ALERT

Encourage sperm banking prior to any definitive treatment.
Unlike seminomas, NSGCTs are not treated with SURGERY/OTHER PROCEDURES following initial chemotherapy. Tumor markers do not normalize in disease where serum tumor markers do not normalize and chemotherapy is reserved for patients with advanced disease. RPLND given suspected disseminated disease postorchiectomy without radiographic evidence of metastasis. Surgery is curative for low-volume nodal disease with 95% cure rate if nodes negative, but may be salvaged with subsequent chemotherapy. High-volume disease (pN2–3—risk of relapse >50%) or tumor left behind; adjuvant BEP chemotherapy decreases relapse to <1%.

Stage IS disease: Elevated tumor markers
- Surveillance: In reliable patients with no risk factors for failure
- The templates should not be strictly upheld should future RPLND be needed. Superior boundary: Renal hilum bilaterally
- Inferior boundary: Edge of aorta down to level where it crosses the ipsilateral common iliac artery. The ipsilateral gonadal vessels and spermatic cord stump are included in the specimen.
- Right-sided template medial boundary: Lateral edge of aorta down to level of RPLND, then from aorta down along the right common iliac artery to where the right ureter crosses.
- Left-sided template medial boundary: Lateral edge of the IVC down to level of the IMA, then from the aorta down along the left common iliac artery to left ureter crossing.
- Postchemotherapy: A full bilateral template is utilized with prospective nerve sparing. The templates should not be strictly upheld should future RPLND be needed.

ADDITIONAL TREATMENT
Radiation Therapy
Unlike seminomas, NSGCTs are not treated with radiation (teratoma is radiosensitive).

Additional Therapies
- SEE Section III “Testis Cancer, Nonseminomatous Germ Cell Tumor” for treatment algorithm.
- Stage IIA disease treatment options
- Surveillance: In reliable patients with no risk factors for failure. No teratoma elements, no lymphovascular invasion, and no embryonal cell carcinoma in the primary. Reliable patient; cure rate >95% with close follow-up
- 20–30% relapse rate; these patients can be salvaged with subsequent chemotherapy. RPLND: Modified unilateral template/ nerve-sparing: 70–75% will have no tumor (pN0)
- Perform within 4–6 wk of CT and 7–10 days of tumor for accurate clinical staging
- >95% cure rate if nodes negative, but may be curative for low-volume nodal disease
- 1% relapse rate
- Chemotherapy: 95% cure rate with BEP

Stage IIB disease
- Postorchiectomy tumor markers positive: induction chemotherapy
- Postorchiectomy tumor markers negative: either RPLND or chemotherapy
- No viable tumor (pN0), observe patient
- Low-volume tumor, surgery curative in 60–90%; surveillance or chemotherapy
- High-volume disease (pN2–3—risk of relapse >50%) or tumor left behind; adjuvant BEP chemotherapy decreases relapse to <1%
- Stage IIIa IIb IIIc or IV disease
- Either 3 or 4 cycles of BEP chemotherapy
- Complete response, observe
- Partial response with residual masses, full bilateral RPLND (nerve sparing if applicable)
- Residual masses: 40% fibrosis, 40% teratoma, 20% viable malignancy
- Teratoma/Therios on pathology. Observe
- Viable tumor and tumor markers are elevated or tumor is left behind; consider salvage chemotherapy
- No viable tumor (pN0), observe patient
- Superiority determined by histology
- Testis Cancer, Nonseminomatous Germ Cell Tumor Algorithm

ONGOING CARE
PROGNOSIS
• Has been divided into good, intermediate, and poor prognosis based on stage and risk factors.
• SEE Section I “International Germ Cell Cancer Collaborative Group (ICCCCG)”
  - Good: 5-yr survival 94%
  - Intermediate: 5-yr survival 83%
  - Poor: 5-yr survival 71%

COMPLICATIONS
- Surveillance: Risk of recurrence, risk for secondary malignancy due to repeat CT imaging
- RPLND
  - Iatrogenic dysfunction can impair fertility; a nerve-sparing template can preserve antegrade ejaculation in more than 90% of cases.
  - Mortality (nephrectomy, fea, lymphatic, paracolic, celiac axis) rate 5–25%; tumor bowel obstruction rate 1–2%, mortality rate <1%
- Chemotherapy
  - Bleomycin: Pulmonary fibrosis. Need to limit IV fluid hydration and supplemental oxygenation
  - Cisplatin: Nephrotoxicity, ototoxicity, peripheral neuropathy
  - Secondary malignancy, especially leukemias, skin malignancies, and lymphomas
  - Metabolic syndrome
  - Infertility (50% with normal semen 2 yr after chemotherapy, 25% remain azoospermic)

FOLLOW-UP
Patient Monitoring
- Physical exam, tumor markers, and imaging (CT, abdomen/pelvic CT)
- Frequency of follow-up may be tailored depending on therapy, stage, and disease risk

Patient Resources
NCCN Testicular Cancer Information. www.cancer.gov/cancertopics/types/testicular

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- International Germ Cell Cancer Collaborative Group (ICCCCG)
- Reference Tables: ICD-10-CA Testis Cancer
- Urol Oncol. Testicular cancer.

CODES
ICD9
- 186.9 Malignant neoplasm of other and unspecified testis
- 752.5 Treated testicle, unspecified
- 752.5 Treated testicle, unspecified
- 186.9 Malignant neoplasm of other and unspecified testis

ICD10
- C62.9 Malignant neoplasm of testis, unspecified
- C62.9 Treated testicle, unspecified
- 752.5 Treated testicle, unspecified
- 752.5 Treated testicle, unspecified

CLINICAL/SURGICAL PEARLS
- An atypical inguinal orchiectomy, tap the residual spermatic cord stump with a long sk suture for identification at future RPLND.
- Lymphatic drainage is unpredictable unless there is a history of scrotal/inguinal surgery.
- Tumor marker half-lives can be followed to assess if they fall appropriately after treatment (should nadir after 5 half-lives).
Embryonal carcinoma is capable of differentiating into embryonic structures, such as mature (tissue) or immature (adult) teratomas and extraembryonic structures such as yolk sac and choriocarcinoma tumors.

Seminoma (or spermatocellular seminoma) is a primitive germ cell neoplasm that cannot further differentiate (unusual in childhood, except with gonadal dysgenesis).

Teratoma: Monodermal (epidermoid cyst) or multiple histologic types present (neve, cartilage, intestinal epithelium, etc.). Benign and no prepubertal transformation.

Yolk sac tumors characterized by Schiller–Duval bodies (Yolk sac in appearance, contain AFP).

Leydig tumors which can secrete testosterone are malignant 10% of time. (Rare in children—40%, increased in adults—50% above 20 years old, infants—10% malignant.) can secrete estrogen or testosterone, and granulosa cells (75% diagnosed within 1 mo of birth) have a common embryonic origin from a mesonephric stem cell.

Gonadoblastomas are small benign tumors found in patients with gonadal dysgenesis, including those who have at least a portion of the Y chromosome. Although benign they have high risk of malignant transformation.

15–20% of all RMS arise from the genitourinary system.

– Most common genitourinary sites are the prostate, bladder, and paratesticular (ovaries and uterus are relatively unusual sites).

– Survival rates vary with site (ovary and paratesticular have a better prognosis than bladder/prostate primaries).

2 main histologic types of RMS

– Embryonal RMS is the most common subtype of RMS and accounts for most of the genitourinary neoplasm.

– Alveolar RMS occurs more commonly in the trunk and extratesticular than in GU, worse prognosis than embryonal tumor.

– Epithelial usually not infectious in pediatrics; likely due to refluxing fluid from urethra. Obtain urine culture. If infected need renal ultrasound to rule out urologic etiology.

– Vascular/lymphatic pathogenesis not known. Body habitus (tall, thin), genetics (risk increased if brother or 1st-degree relative has vascular Mayo), or systemic venous anomalies (“nutcracker” by SMA, left renal vein insertion), and rarely central outflow obstruction from tumors.

– In neotens and young children “hematoma” will be used to describe a communicating hydrocele with a “hematoma sac” present though no organ protrusion present: Patient process vasa

ASSOCIATED CONDITIONS

- Hypercalcemia:

  - Testicular tumor: Undescended testis (UOT), gonadal dysgenesis, precocious puberty in non–germ cell tumors (NGCT).

- Hematoma: 1–5% lesions, 3–10% found in preterm infants, 15% bilateral, clinical symptoms hydrocele: 2%, asymptomatic process palpable present—46% of time. (Rare in children—40%, increased in adults—50% above 20 years old, infants—10% malignant.)

- Vascular: ~0–10% old, increasing to 15% through puberty into adulthood.

- Paratesticular tumors: Very rare, bimodal—infancy and adolescence.

- Epididymitis: Less common than adults

GENERAL PREVENTION

- One in three orchidopexy reduces risk in undescended testes.

- USPSTF: Against routine screening for testicular cancer in asymptomatic adolescent and adults including routine testicular self-exams.

- American Cancer Society suggests that men with family history do monthly self-exams.

DIAGNOSIS

- Rationale testicular mass (testicular tumor)

- Acute onset of pain (torsion, epididymitis)

- Symptoms of precocious puberty (tumors—germ cell tumors)

- Painful scrotal mass (testicular tumor)

- Subacute pain (varicocele)

- Abnormal laboratory test (testosterone value)

PHYSICAL EXAM

- Systemic exam identifying intrascrotal structures (testicular mass vs. intraabdominal mass).

- Testicular aspirate from scrotal mass with scrotal US.

- Solid masses do not transilluminate

- Hydrocele transilluminates (communicating if fluid manipulated back into abdomen)

- Solid masses do not transilluminate:

  - Vascular tumors (“bag of worms”)

  - If does not diminish when supine under manual pressure may be due to tumor.

- Lap: Lymphoma or retinoblastoma

- Breast exam, signs of virilization (consider adrenal tumor)

- Breast exam, signs of virilization (consider adrenal tumor) for NGCT tumors

DIAGNOSTIC TESTS & INTERPRETATION

- Core biopsy or fine needle aspiration

- Bulldog biopsy (in pediatrics and extremities)

- Needle biopsy (anywhere including GU)

- Metastatic workup

BASICS

DESCRIPTION

- In contrast to adults, testicular tumors in children are often benign including teratoma, dermoid, and epidermoid cyst.

- The majority of malignant germ cell tumors in children are yolk sac tumors.

- Differentiate testicular mass from scrotal wall and paratesticular mass with scrotal US.

- The most common causes of scrotal swelling or mass in pediatric includes hernia (organ protrusion required) and hydrocele (likely communicating in younger children), with lesions such as varicocele (see scrotal section), scrotal wall swelling (infant bite or nephrotic syndrome), with testicular neoplasms less common (peak incidence at 2 yr old and adolescence).

- Though very rare, most common malignant paratesticular tumor is rhabdomyosarcoma.

EPIDEMIOLOGY

Incidence

- Testicular tumors: (tumor registry data not presented due to reporting bias toward yolk sac). Total 0–3/1,000,000 males, 2% of

  - Testis (well differentiated) — 66%

  - Yolk sac (endothelial sinus) tumor 15%

  - Stromal tumors — 15%

  - Gonadal blastoma — 1%

  - Lymphoma testicular primary: Rare

  - Epidermoid cyst: < 1%

Prevalence

– N/A

RISK FACTORS

- Cryptorchidism: Prepubertal germ cell tumors (5.1%)

- Congenital adrenal hyperplasia (CAH): In boys often presents with precocious puberty. Adrenal excess, commonly present along the spermatic cord and in the testicular bursa, may hypertrophy in patients with CAH, leading to testicular nodules that are clinically indistinguishable from testicular tumors.

- Klinefelter syndrome

- Family history of testicular cancer

- More common in white men than black men

GENETICS

- Gonadal blastoma is associated with gonadal dysgenesis and a 45X0/45XY karyotype.

- Yolk sac tumors: Abnormalities: 1p, 6q, 3p

- Large-cell calcifying Leydig tumors are associated with Peutz–Jeghers syndrome and Carney complex.

- No clear genetic etiology exists for teratoma, dermoid, and granulosa tumor.

PATHOPHYSIOLOGY

- Non–germ cell and germ cell tumors originate from the olfactory epithelium and primordial germ cells, respectively

- Torsion in germ cells can evolve into seminoma or embryonal carcinoma

- Embryonal carcinoma is capable of differentiating into embryonic structures, such as mature (tissue) or immature (adult) teratomas and extraembryonic structures such as yolk sac and choriocarcinoma tumors.

- Seminoma (or spermatocellular seminoma) is a primitive germ cell neoplasm that cannot further differentiate (unusual in childhood, except with gonadal dysgenesis).

- Teratoma: Monodermal (epidermoid cyst) or multiple histologic types present (neve, cartilage, intestinal epithelium, etc.). Benign and no prepubertal transformation.

- Yolk sac tumors characterized by Schiller–Duval bodies (Yolk sac in appearance, contain AFP).

- Leydig tumors which can secrete testosterone are malignant 10% of time. (Rare in children—40%, increased in adults—50% above 20 years old, infants—10% malignant.) can secrete estrogen or testosterone, and granulosa cells (75% diagnosed within 1 mo of birth) have a common embryonic origin from a mesonephric stem cell.

- Gonadoblastomas are small benign tumors found in patients with gonadal dysgenesis, including those who have at least a portion of the Y chromosome. Although benign they have high risk of malignant transformation.

- 15–20% of all RMS arise from the genitourinary system.

- Most common genitourinary sites are the prostate, bladder, and paratesticular (ovaries and uterus are relatively unusual sites).

- Survival rates vary with site (ovary and paratesticular have a better prognosis than bladder/prostate primaries).

- 2 main histologic types of RMS

- Embryonal RMS is the most common subtype of RMS and accounts for most of the genitourinary neoplasm.

- Alveolar RMS occurs more commonly in the trunk and extratesticular than in GU, worse prognosis than embryonal tumor.

- Epithelial usually not infectious in pediatrics; likely due to refluxing fluid from urethra. Obtain urine culture. If infected need renal ultrasound to rule out urologic etiology.

- Vascular/lymphatic pathogenesis not known. Body habitus (tall, thin), genetics (risk increased if brother or 1st-degree relative has vascular Mayo), or systemic venous anomalies (“nutcracker” by SMA, left renal vein insertion), and rarely central outflow obstruction from tumors.

- In neotens and young children “hematoma” will be used to describe a communicating hydrocele with a “hematoma sac” present though no organ protrusion present: Patient process vasa.
DIFFERENTIAL DIAGNOSIS

See Section I and II “Individual Tumor Types”

DIAGNOSTIC PROCEDURES/SURGERY

Biopsy not indicated. The diagnostic procedure of choice is the radical orchiectomy.

Imaging

• Painless scrotal mass: history, CT scan
• Painful scrotal mass: CT scan, ultrasound

Pathologic Findings

See Section I and II “Individual Tumor Types”

DIFFERENTIAL DIAGNOSIS

• Painful scrotum:
  – Varicocele: Fullness and not a firm mass; changes with position
  – Testis tumor of adrenogenital syndrome
  – Metastatic tumors: Unusual in childhood

• Painful perineum:
  – Testicular tumor: Germ cell tumors: Yolk sac tumor
  – Testicular cysts
  – Spermatocele (epididymal cyst): Uncommon

• Scrotal edema (insect bite, nephrotic syndrome, Henoch–Schönlein purpura, Fournier gangrene)
  – Paratesticular rhabdomyosarcoma (bimodal age peak: 3–4 and teens)

• Masses in the scrotum:
  – Testicular tumor: Germ cell tumors: Yolk sac tumor, teratoma, seminoma, embryonal cell carcinoma, choriocarcinoma, Seminial gland tumors; Leydig, Sertoli cell, granulosa cell
  – Metastatic tumors: Unusual in childhood
  – Mixed germ cell and stromal tumor (gonadoblastoma)
  – Hamartoma, carcinoma in situ, neurofibroma

• Testis tumor of adrenogenital syndrome
  – Leukemia or lymphoma
  – Viral infection: Herpes and not a firm mass; changes with position

GENERAL MEASURES

• If concern for tumor obtain tumor markers pre- and postoperatively (1–4 wk)
• Discuss sperm banking, especially if chemotherapy needed
• Do not make incision through scrotum (inguinal incision only)
• Use long tag nonabsorbable suture when ligating spermatic cord
• Do not make incision through scrotum (inguinal incision only)

MEDICATION

• First Line: Chemotherapy for all yolk sac tumor stage 1 or greater or other germ cell tumor
• Platinum based for other nonseminomatous (choriocarcinoma, choriocarcinoma, and thymic cysts)

SURGERY/OTHER PROCEDURES

• Prepubertal teratoma is uniformly benign
• Prepubertal testicular teratomas, Leydig and Sertoli cell tumors are benign; orchiectomy or testicular-sparing surgery is curative and no additional therapy is needed
• Yolk sac tumor or other malignant tumor; radical orchidectomy and observation if low stage
• Retropertitoneal lymph node dissection (RPLND):
  – Ipsilateral RPLND before chemo.
  – Only indicated: 90% of yolk sac tumors are stage I at presentation; 85% 6-yr survival in stage 4 patients

RPLND: Retrograde ejaculation, lymphocele

ADDITIONAL TREATMENT RADIATION THERAPY

Used in rhabdomyosarcoma

ADDITIONAL THERAPIES

TESTIS CANCER, SEMINOMA

Robert B. Den, MD
Mark Hurwitz, MD

**PATHOPHYSIOLOGY**

*Rarely presents as an extragonadal GCT in a site remote from the testicle.*

*Hematogenous dissemination is much less common than in NSGCT.*

*β-hCG elevation can sometimes be seen in seminoma.*

*The presence of elevated AFP during evaluation usually suggests nonseminomatous elements.*

*Due to slower growth pattern, relapses tend to be later than with NSGCT, and many can occur 2–3 yr after chemotherapy.*

**ASSOCIATED CONDITIONS**

*Increased risk in patients with cryptorchidism; risk is >30% times the general population.*

**GENERAL PREVENTION**

*Ultrasound or orchidectomy useful risk in undescended testicles.*

**DIAGNOSIS**

**HISTORY**

*Family history or swelling in the testes.*

*History of undescended testicle or inguinal surgical procedure as a child.*

**PHYSICAL EXAM**

*Palpate the testes bilaterally.*

*Examine the groin for evidence of surgical scar (prior orchidectomy).*

*Inspect for lymphedema of the groin or lower extremities.*

*Lymphatic spread is not typically inguinal; however, prior scrotal surgery may change lymphatic drainage.*

**DIAGNOSTIC TESTS & INTERPRETATION**

*CT of chest, abdomen, and pelvis to evaluate for metastatic disease.*

*Chest x-ray: To rule out metastatic lesions.*

*CBC and chemistry battery.*

*Beta-HCG.*

*Serum AFP.*

*Beta-绒毛膜促性腺激素 elevation can sometimes be seen in seminoma.*

*Cells of varying size that resemble maturing spermatogonia (peak age >50).*

*Does not stain for PLAP.*

**DIFFERENTIAL DIAGNOSIS**

*Adenocarcinoma of the rete testis.*

*Adequate lymphatic drainage.*

*Inguinal lymphadenopathy.*

*Right-sided tumors spread in the following order: The left-sided tumors tend to spread in the following order.*

*The slow growth characteristics of most seminomas result in them most commonly being diagnosed at an early stage (≤50% stage I).*
Radiation Therapy

ADDITIONAL TREATMENT

SURGERY/OTHER PROCEDURES

First Line

Radical inguinal orchiectomy

Radical orchiectomy (cIS), are initially treated with platinum-based chemotherapy according to the IGCCCG risk stratification.

Stage IA,B: Radical orchiectomy and adjuvant RT in persistently elevated tumor markers following stage I or II (B3 bulky) disease.

Stage I: 98–100%

Stage II (B1/B2 nonbulky): 98–100%

Stage II (B1/B2 bulky) and Stage III: >90% complete response rate to chemotherapy and 86% durable response to conventional chemotherapy.

Second Line High dose chemotherapy or clinical trial

Medication

First Line

RPLND is not usually for seminoma.

Carboplatin:

Stage I:

Stage II (B3 bulky) and stage III:

Stage II (B1/B2 nonbulky): 98–100%

Stage II (B1/B2 bulky) and stage III: >90%

Response rates to chemotherapy seem to be slightly better without prior radiation.

COMPLICATIONS

Infertility, GI complications, and possible induction of secondary malignancies are a concern following adjuvant RT.

Involvement of retroperitoneal lymph nodes may produce backache.

Follow-up

Patient Monitoring

Surveillance:

- Hb, AFP, β2-MG, LDH:
  - Every 3–4 mo for yrs 1–2
  - Every 6–12 mo for yrs 3–4, then annually
  - Adenoviral/epidemic CT annually for yrs 1–3, then every 4–6 mo for yrs 4–5
  - ORX as clinically indicated for yrs 1–5

- Carboplatin:
  - Every 3–4 mo for yrs 1–2
  - Every 6–12 mo for yrs 3–4, then annually
  - Adenoviral/epidemic CT annually for yrs 1–3
  - ORX as clinically indicated
  - RT:
    - Every 3–4 mo for yrs 1–2
    - Every 6–12 mo for yrs 3–4
  - Adenoviral/epidemic CT annually for yrs 1–3 (for patients post only para-aortic RT)
  - ORX as clinically indicated

Additional Therapy

- Active surveillance for low-risk, early disease:
  - Avoids unnecessary treatment and related side effects

- CT every 4–6 mo, reduce interval after ~5 yr

- Traditional risk factors that increase the recurrence risk: tumor size >4 cm, invasion of the rete testis, anaplastic features, small vessel invasion

- The role of salvage chemotherapy, surgical removal, or RT of persistent masses detected by CT continues to be controversial.

Complementary & Alternative Therapies

Patients should consider sperm banking prior to treatment to aid in avoiding risk of infertility.

Aplastic seminoma is no longer recognized as distinct entity.
TESTIS, LEYDIG CELL TUMOR

Austin R. Younger, MD
James S. Rosofsky, MD

DESCRIPTION
Leydig cell tumors (LCTs) are hormonally active steroid-secreting tumors that may produce feminizing/virilizing syndromes.

- Most common sex conditional tumors
  - Neoplasms containing (leydig, Sertoli), granulosa, or thal cell (commonly referred to as nonseminomas)
- Usually benign, 10% malignant variants reported in adults only (1)
- TNM staging follows current NCCN Guidelines for Testis Cancer

EPIDEMIOLOGY (1)
- An estimated 8,820 new cases of testicular cancer were diagnosed in 2014
- LCTs represent 1–3% of all testicular neoplasms
- LCTs are not associated with cryptorchidism
- Equal incidence between right and left testis with 4–10% occurring bilaterally
- Bimodal distribution with peak incidences occurring between ages 4–5 and 30–60
- Most common sex cord/stromal tumors
- LCTs usually secrete testosterone, may also secrete other androgens, corticosteroid, estrogen, and progesterone.

PATHOPHYSIOLOGY
- Leydig cells are located in the interstitium of testicle
- Produce testosterone to estrogens from aromatase conversion (seen in animal studies only)
- Hypothalamic–pituitary axis is directly involved in feedback regulation
  - Reinke crystals: Pathognomonic for LCT, rhomboid/cylindrical crystals, pale staining within cytoplasm and nucleus.
  - Malignant LCT: Larger, hemorrhage/necrosis present, replace or spread stromal/tubular architecture
- Vital role in development of male secondary sex characteristics and spermatogenesis
- In neoplasia, feedback regulation is disrupted resulting in uncontrolled hormone production.

DIAGNOSIS
- Low estradiol, increased testosterone, gynecomastia, and hyperplastic lesion on ultrasound are highly suspicious for LCT
- Histopathology confirms diagnosis

HISTORY
- Children commonly present with:
  - Precocious puberty due to androgen secreting tumors; irreversible and profound physical changes—early diagnosis is critical
- Feminization symptoms—low energy, anhedonia, change in penile length, deepened voice, testicular atrophy, gynecomastia, infertility
- Adults commonly present with:
  - Nontender testicular mass/nodule
  - Incidental finding on imaging for other conditions
  - Premature testicular development to identify any deviation in normal growth and maturation

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - All other tests should be within normal limits if malignancy not present
  - Virilization occurs due to unopposed testosterone/estrogen production independent of LH stimulation.
  - Virilizing signs are often not observed in adults.
- Imaging
  - CT chest/abdomen/pelvis: If concern for malignancy, testicular ultrasound preferred imaging if mass is palpable

PHYSICAL EXAM
- A unilateral mass is palpable in 90% of cases with careful exam
- Hypothalamic imbalance responsible for physical changes
  - Virilizing changes
    - Children: Precocious puberty, early growth, early change in penile length, deepened voice, increased muscle mass
    - Adults: Usually asymptomatic
  - Feminizing changes
    - Children: Delayed maturational, testicular atrophy, gynecomastia
    - Adults: Female hair distribution, gynecomastia, testicular atrophy

DIAGNOSTIC PROCEDURES/SURGERY
- Historically, radical inguinal orchietomy was gold standard treatment
- Testis-sparing surgery (TSS): Enucleation of tumor
  - Historically, radical inguinal orchiecetomy was gold standard for treatment
  - Some cases; no evidence of local recurrence or metastases on long-term follow-up (3,5)

PATHOLOGIC FINDINGS
- Gross pathology
  - Benign LCTs: 3–5 cm, sharply delineated, solid mass, embedded within testis, displaces normal stromal/hilar architecture
  - Brown to yellow-white depending on total lipid content
- Malignant LCT: Larger, >5 cm, infiltrative margins, hemorrhage/necrosis present, replace or spread beyond testicular parenchyma
- Microscopic pathology
  - Testicular tumors, large polygonal cells with eosinophilic/clear granular cytoplasm, round regular nuclei, eosinophilic/gray, prominent nucleoli
  - Neoplastic Leydig cells: pathognomonic for LCT
  - Malignant lesions: Lobular, minimally invasive tumor cells with increased lipid inclusions

LITERATURE CITED

• Findings that correlate with malignancy
  – Cytologic/histologic atypia, increased mitotic activity
  – Local invasion of the capsule, lymphovascular invasion
  – Increased expression of androgen receptors
  – Immunoexpression of androgen receptors

DIFFERENTIAL DIAGNOSIS

• Testicular masses (see Section I: “Testis Cancer, Pediatric, General Considerations”)
• Precocious puberty
• Adrenocortical syndromes
• Gynecomastia/feminization
• Pituitary lesions
• Paraneoplastic syndromes

TREATMENT

GENERAL MEASURES

• Management is primarily surgical
• Radical orchiectomy is the gold standard

SURGERY/OTHER PROCEDURES

• Radical orchiectomy
• Testicular sparing surgery

• Testis-sparing surgery (TSS) is a reasonable option in certain cases and has no reported increased risk of local recurrence or metastasis compared with radical orchiectomy.

• Findings that correlate with malignancy
  – Cytologic/histologic atypia, increased mitotic activity
  – Local invasion of the capsule, lymphovascular invasion
  – Increased expression of androgen receptors
  – Immunoexpression of androgen receptors

DIFFERENTIAL DIAGNOSIS

• Testicular masses (see Section I: “Testis Cancer, Pediatric, General Considerations”)
• Precocious puberty
• Adrenocortical syndromes
• Gynecomastia/feminization
• Pituitary lesions
• Paraneoplastic syndromes

ADDITIONAL TREATMENT

Radiation Therapy

• Radiotherapy may be used as a preoperative or postoperative treatment.

ADDITIONAL THERAPIES

• Observation
• Chemotherapy

ONGOING CARE

• Surveillance and follow-up are important for patients with Leydig cell tumors.

CLINICAL/SURGICAL PEARLS

• Leydig cell tumors (LCTs) are hormonally active steroid-secreting tumors that may produce feminizing virilizing syndromes.
• LCTs are usually benign; 10% malignant variants reported in adults only.
• Low estradiol, increased testosterone, andropause, and hypochlonic lesion on ultrasound are highly suspicious for LCT.
• Social exploration with frozen section is reliable in diagnosing LCT.
• Testicular sparing surgery (TSS) is a reasonable option in certain cases and has no reported increased risk of local recurrence or metastasis compared with radical orchiectomy.
No studies exist at this time

DESCRIPTION
- Orchalgia is scrotal or testicular pain
- Acute or chronic
- Intermittent or constant
- Unilateral, bilateral, or alternating
- Characteristics
  - Localized to scrotum
  - May radiate to groin, perineum, back, or legs
  - Chronic orchalgia
  - Lasting >3 mo
  - Concurrent or intermittent pain.
- No specific cause is identified in most cases.
- Secondary gains with malingering
- Depression
- Life stressors
- Current life stressors
- Social support
- Neutropathic conditions
  - Diabetes
  - Polymyalgia rheumatica
  - RSD
- Pain psychology
- Nerve entrapment (ilioinguinal or genitofemoral)
- Inguinal hernia (incarcerated, other)
- Testicular tumors
- Testicular torsion
- Torsion of testicular/epididymal appendices
- Epididymitis and epididymo-orchitis
- Viral orchitis
- Prostatitis
- Epididymal granulomas
- Scrotal/inguinal mass
- Herniated intervertebral disc

ASSOCIATED CONDITIONS
- Often idiopathic (~15%)
- Can be associated with:
  - Previous surgery (vasectomy, hernia repair)
  - Trauma
  - Intermittent torsion
  - Hydrocele, varicocele, spermatocele
  - Tumor
  - Infection
  - Herniated intervertebral disc
  - Vasculitis (polymyalgia rheumatica)

GENERAL PREVENTION
- USPSTF: Against routine screening for testicular cancer in asymptomatic adolescent and adults including routine testicular self-exams.
- American Cancer Society suggests that men with family history do monthly self-exams.

ALERT
- Acute onset of testicular pain in a child is most likely torsion, and emergent evaluation is indicated, early surgical intervention; do not delay surgery for imaging.

TESTS, PAIN (ORCHALGIA)

Alosh Madala, MD
Dmitry Nikolovsky, MD

BASICS

PREVALENCE
- Chronic testicular pain
  - Idiopathic 25–50%
  - Postvasectomy chronic orchalgia
  ~15%

RISK FACTORS
- Organic/physical risk factors
  - Previous trauma or surgery
  - Post-vasectomy pain syndrome in ±43% of men who have undergone this procedure
  - Posthemia repair
  - Sperm granuloma following vasectomy
- Neuropathic conditions
  - Diabetic neuropathy
  - Neurontin withdrawal from migraine
- Psychological risk factors
  - Life stresses
  - Depression
  - Secondary gain with malingering

GENETICS
- No studies exist at this time

PATHOPHYSIOLOGY
- Poorly understood
- Idiopathic in most cases
- Tests involvement
  - Sympathetic nerve supply from T10–T12 segments
  - Accompany the internal spermatic vessels
  - Penetrate the tunica albuginea
  - Accompany the internal spermatic vessels
  - Sympathetic nerve supply from T10–T12 segments
- Secondary gain with malingering
  - Depression
  - Life stressors
  - Social support
  - Neutropathic conditions
  - Diabetes
  - Polymyalgia rheumatica
  - RSD
- Pain psychology
  - Nerve entrapment (ilioinguinal or genitofemoral)
  - Inguinal hernia (incarcerated, other)
  - Testicular tumors
  - Testicular torsion
  - Torsion of testicular/epididymal appendices

DIAGNOSIS

HISTORY
- Onset, location, duration, quality, aggravating (exercise, sexual intercourse, or ejaculation) and relieving factors.
- Visual analog scale (VAS) of 0–10 helps quantify degree of pain (~15%)
- Consult with multiple physicians including urologists
- Multiple treatments (antibiotics, anti-inflammatory drugs)
  - Little or no relief
  - Severe pain
  - Refractory to treatment
  - Referred pain (nerve root irritation)
  - Psychogenic
- Referral (venous occlusion, renal insufficiency)
- Medical causes: Diabetic neuropathy, polyarteritis nodosa
  - Postoperative (vasectomy, inguinal herniorrhaphy)
  - Inguinal hernia (incarcerated, other)
  - Testicular tumor
  - Testicular torsion
  - Testicular vesiculation
  - Testicular tumor
  - Testicular vasovasostomy from sexual arousal without ejaculation
  - Testicular pain with sexual activity
  - Chronic pelvic pain syndrome (CPPS)

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Urine analysis and culture
  - Bacterial and after prostatic massage
  - Serum analysis (for chronic epididymitis)
- Consider STD/STI screening

IMAGING
- Scrotal US with color flow doppler
  - Evaluate scrotal contents
  - Rule out testicular torsion and tumor

DIAGNOSTIC PROCEDURES/SURGERY

Cystoscopy and urodynamics are of limited value

PATHOLOGIC FINDINGS
Based on etiology

DIFFERENTIAL DIAGNOSIS (2)
- Chronic pelvic pain syndrome (CPPS)
- Chronic epididymitis
- Hydrocele, spermatocele
- Idiopathic orchalgia
- Testicular tumors
  - Paratesticular tumor
  - Testicular abscess
  - Epididymal or epididymo-orchitis
  - Urethritis
  - Prostatitis
  - Viral orchitis
  - Testicular abscess
  - Hydrocele, spermatocele
  - Idiopathic orchalgia
  - Testicular tumors
  - Paratesticular tumor
  - Testicular abscess
  - Epididymal or epididymo-orchitis
  - Urethritis
  - Prostatitis
  - Viral orchitis
  - Testicular abscess
  - Hydrocele, spermatocele
  - Idiopathic orchalgia
  - Testicular tumors
  - Paratesticular tumor
  - Testicular abscess
  - Epididymal or epididymo-orchitis
  - Urethritis
  - Prostatitis
  - Viral orchitis
  - Testicular abscess
  - Hydrocele, spermatocele

MEDICATION

GENERAL MEASURES
- For acute testicular pain: See Section 1 “Acute Scrotum”
- For chronic testicular pain
  - Scrotal support
  - Avoid physical activity
  - Hot baths

MEDICATION

FIRST LINE
- NSAIDs
  - Variable and usually temporary relief
- Regimens described include ibuprofen 400–600 mg q PO bid for 1 mo

TREATMENT

502
ADDITIONAL THERAPIES (10,11)

- Antidepressants and anticonvulsants - Demonstrated benefit in chronic idiopathic orchalgia
- Poor response to postvasectomy pain
- Tricyclic antidepressants - Amitriptyline 10–25 mg qhs
- Gabapentin 300 mg titrated up to 6,300 mg daily
- Denervation of spermatic cord - Through surgical or percutaneous means

RADIATION THERAPY

- Sacral nerve stimulation - May be helpful in patients with spinal disk and back problems with nerve root irritation
- Physical therapy
- Vasoavasostomy in the setting of postvasectomy pain
- Epididymectomy
- Denervation of spermatic cord (3,9)

The following are used for the management of acute testicular pain in a child: See Section I

- Tricyclic antidepressants
- Antidepressants and anticonvulsants
- Antibiotics
- - Adrenergic antagonists
- - Doxycycline 100 mg PO BID or ciprofloxin 250–500 mg PO BID for 2–3 wk

SECOND-LINE (5.6)

- Acute testicular pain in a child: See Section I "Torsion, Testis or Testicular/Epidermidal Appendages"
- The following are used for the management of chronic pain in an adult:
  - Minimally invasive treatment options (7,8)
  - Denervation of spermatic cord
  - Block with local anesthetic
- Orchiectomy
- - Testis: May continue to have pain
  - Inguinal approach superior to scrotal
- - 75% patients have relief after surgical removal of varicoceles, hydroceles, spermatoceles, or intermittent torsion.
- Epididymectomy
- - Poor results except in the setting of postvasectomy pain syndrome
- Vasovasectomy in the setting of postvasectomy pain

ADDITIONAL TREATMENT

- Physical therapy
  - May be helpful in patients with spinal disk and back problems with nerve root irritation

RADIATION THERAPY

- NA

ADDITIONAL THERAPIES (10,11)

- Pulsed radiofrequency denervation of the spermatic cord (4)
- Testicular scrotal block with local anesthetic
- Sacral nerve stimulation - 80% decrease in pain

CONCLUSION

- Oral gabapentin or pregabalin (neurontin) treatment for refractory neuropathic testicular pain.
- Consider gabapentin or nortriptyline before considering surgery.
- Psychotherapy
- - Should be strongly considered before surgical intervention
- Pelvic muscle exercises

ONGOING CARE

PROGNOSIS

Depends on etiology

COMPLICATIONS

- Surgery
  - Epididymectomy may result in loss of testicle or infertility

FOLLOW-UP

Patient Monitoring

Periodic follow-up with urology or other providers depending on etiology (if known)

PATIENT RESOURCES

- Urology Care Foundation: Epididymitis and Orchitis.
  - http://www.urologyhealth.org/urology/index.html?article=114&display=1

CODES

ICD-9

367.89 Other pain disorders related to psychological factors
688.89 Other specified disorders of male genital organs
993.14 Other injury of external genitals

ICD-10

P54.81 Pain disorder exclusively related to psychological factors
N80.8 Other specified disorders of male genital organs
S39.94 Other unspecified injury of external genitals, initial encounter

CLINICAL/SURGICAL PEARLS

- The presence or absence of pain or tenderness alone cannot reliably rule in or out benign vs. malignant processes in the scrotum or testes.
- Physical exam is often normal with testicular pain.
- Ultrasound is the most valuable study.
- Surgical options should only be considered after medical and conservative management fails for chronic testicular pain.
TESTIS, SERTOLI CELL TUMOR
Tariq A. Khemees, MD
Ahmad Shabegis, MD, FACS

PATHOPHYSIOLOGY
- Sertoli cells are supporting cells of the testis.
  - During fetal development: Secrete anti-Mullerian hormone, which leads to regression of Mullerian ducts.
  - During adulthood: Promote differentiation of spermatogonia.
- Normally, Sertoli cells do not have aromatase activity (the enzyme that converts testosterone to estradiol); however, neoplastic Sertoli cells may express aromatase.
- Excess estrogen in prespermatogenic boy will lead to accelerated skeletal maturation and gynecomastia.

ASSOCIATED CONDITIONS
- Gynecomastia
  - Carney complex (CNC)
  - Peutz–Jeghers syndrome (PJS)
  - Tuberous sclerosis (TS)
- Breast exam: Look for:
  - Mass
  - Tenderness
  - Feminization, hair pattern, and other signs of estrogen access
  - Bone scan
- Imaging:
  - Testicular US
  - LCCSCT:
    - Bilateral in 20% of reported cases, especially in familial syndromes
    - Usually appear as solid, well-circumscribed, and hypervascularized masses
    - Bilateral increase in testicular volume
    - Occasionally cysts are seen
    - Calcifications: Microcalcifications within the tumor mass
    - Christmas tree-like appearance of multiple calcifications in syndromic LCCSCT is almost always pathognomonic for this tumor
  - Metastatic workup includes:
    - Chest x-ray
    - CT pelvis and abdomen
    - Bone scan

Diagnostic Procedures/Surgery
- Excisional biopsy usually by radical orchiectomy, can be curative
- Fine needle biopsy or nonexcisional biopsy of mass should never be done due to the risk of spread of the more common malignant tumors such as embryonal cell carcinoma or seminoma
- Partial orchietomy, inguinal approach for patient with familial syndrome

Pathologic Findings
- Gross: Generally well circumscribed, yellow-gray, and lobulated on cut surface
- Histologically:
  - Solid, tubular, or cord-like growth pattern of spermatogonia
  - Neoplastic Sertoli cells may express aromatase.
- Immunophenotype:
  - Neoplastic Sertoli cells do not have aromatase expression.
- Histologic subtypes:
  - Classic or tumors that are not otherwise specified:
    - Large-cell calcifying Sertoli cell tumor
      - Mean age of 45 yr
      - Low malignant potential (around 10–20%)
      - Mostly have benign clinical course, but malignancy can occur especially in older ages
      - Bilateral: Early and late onset
      - Frequently associated with MNS
  - Tuberous sclerosis (TS): Autosomal dominant caused by TSC1 and TSC2 mutations and characterized by:
    - Mental retardation
    - Facial angiofibromas
    - Spotty skin pigmentation
    - Multiple hamartomatous polyps along the whole gastrointestinal tract
    - Malignant renal tumors
    - Cardiac rhabdomyomas
    - Angiomyolipomas
    - Inguinal lymphadenopathy
    - Angiomyofibroblastoma
    - Intrahepatic cholestatic syndrome
    - Synganglium disease
    - Christmas tree-like appearance of multiple calcifications in syndromic LCCSCT is almost always pathognomonic for this tumor
  - Peutz–Jeghers syndrome (PJS):
    - Malignant tumors frequently occur in gastrointestinal tract
  - Tuberous sclerosis (TS):
    - Malignant tumors frequently occur in renal tract
  - Breast:
    - Breast: Look for:
      - Mass
      - Tenderness
      - Feminization, hair pattern, and other signs of estrogen access
      - Bone scan
- Lab:
  - See steroid: Check for age-appropriate levels of:
    - LH
    - FSH
    - Androgens
    - Estrogen
    - Progesterone
  - Tumor markers:
    - AFP is usually negative
    - hCG is usually negative
    - Paraneoplastic alkaline phosphatase is usually negative

RISK FACTORS
- 40% of LCCSCT are hereditary and are associated with multiple neoplasia syndromes (MNSs) namely:
  - Carney complex (CNC)
  - Peutz–Jeghers syndrome (PJS)
  - Tuberous sclerosis (TS)
- Genetics:
  - Autosomal dominant; mainly caused by STK11 gene mutations and characterized by:
    - Mental retardation
    - Facial angiofibromas
    - Multiple hamartomatous polyps along the whole gastrointestinal tract
    - Angiomyolipomas
    - Intrahepatic cholestatic syndrome
    - Synganglium disease
    - Christmas tree-like appearance of multiple calcifications in syndromic LCCSCT is almost always pathognomonic for this tumor
- Other causes:
  - Malignant tumors frequently occur in renal tract
  - Breast:
    - Breast: Look for:
      - Mass
      - Tenderness
      - Feminization, hair pattern, and other signs of estrogen access
      - Bone scan

DIAGNOSTIC TESTS & INTERPRETATION
- Lab:
  - See steroid: Check for age-appropriate levels of:
    - LH
    - FSH
    - Androgens
    - Estrogen
    - Progesterone
  - Tumor markers:
    - AFP is usually negative
    - hCG is usually negative
    - Paraneoplastic alkaline phosphatase is usually negative

BASICS
- Genetics:
  - Autosomal dominant; mainly caused by STK11 gene mutations and characterized by:
    - Mental retardation
    - Facial angiofibromas
    - Multiple hamartomatous polyps along the whole gastrointestinal tract
    - Angiomyolipomas
    - Intrahepatic cholestatic syndrome
    - Synganglium disease
    - Christmas tree-like appearance of multiple calcifications in syndromic LCCSCT is almost always pathognomonic for this tumor
  - Peutz–Jeghers syndrome (PJS):
    - Malignant tumors frequently occur in gastrointestinal tract
  - Tuberous sclerosis (TS):
    - Malignant tumors frequently occur in renal tract
  - Breast:
    - Breast: Look for:
      - Mass
      - Tenderness
      - Feminization, hair pattern, and other signs of estrogen access
      - Bone scan

DIAGNOSIS
- HISTORY
  - Familial history of MNS
  - Growth spurt
  - Fertility
  - Lab:
    - See steroid: Check for age-appropriate levels of:
      - LH
      - FSH
      - Androgens
      - Estrogen
      - Progesterone
    - Tumor markers:
      - AFP is usually negative
      - hCG is usually negative
      - Paraneoplastic alkaline phosphatase is usually negative

IMAGING
- Testicular US
  - Usually appear as solid, well circumscribed, and hypervascularized mass
  - Bilateral increase in testicular volume
  - Occasionally cysts are seen
  - Calcifications: Microcalcifications within the tumor mass
- Chest x-ray
- CT pelvis and abdomen
- Bone scan

Diagnostic Procedures/Surgery
- Excisional biopsy usually by radical orchiectomy, can be curative
- Fine needle biopsy or nonexcisional biopsy of mass should never be done due to the risk of spread of the more common malignant tumors such as embryonal cell carcinoma or seminoma
- Partial orchietomy, inguinal approach for patient with familial syndrome

Pathologic Findings
- Gross: Generally well circumscribed, yellow-gray, and lobulated on cut surface
- Histologically:
  - Solid, tubular, or cord-like growth pattern of spermatogonia
  - Neoplastic Sertoli cells may express aromatase.
- Immunophenotype:
  - Neoplastic Sertoli cells do not have aromatase expression.
- Histologic subtypes:
  - Classic or tumors that are not otherwise specified:
    - Low malignant potential (around 10–20%)
    - Mostly have benign clinical course, but malignancy can occur especially in older ages
    - Bilateral: Early and late onset
    - Frequently associated with MNS
  - Tuberous sclerosis (TS):
    - Autosomal dominant caused by TSC1 and TSC2 mutations and characterized by:
    - Mental retardation
    - Facial angiofibromas
    - Multiple hamartomatous polyps along the whole gastrointestinal tract
    - Angiomyolipomas
    - Intrahepatic cholestatic syndrome
    - Synganglium disease
    - Christmas tree-like appearance of multiple calcifications in syndromic LCCSCT is almost always pathognomonic for this tumor
  - Peutz–Jeghers syndrome (PJS):
    - Malignant tumors frequently occur in gastrointestinal tract
  - Tuberous sclerosis (TS):
    - Malignant tumors frequently occur in renal tract
  - Breast:
    - Breast: Look for:
      - Mass
      - Tenderness
      - Feminization, hair pattern, and other signs of estrogen access
      - Bone scan

DIAGNOSTIC TESTS & INTERPRETATION
- Lab:
  - See steroid: Check for age-appropriate levels of:
    - LH
    - FSH
    - Androgens
    - Estrogen
    - Progesterone
  - Tumor markers:
    - AFP is usually negative
    - hCG is usually negative
    - Paraneoplastic alkaline phosphatase is usually negative

IMAGING
- Testicular US
  - Usually appear as solid, well circumscribed, and hypervascularized mass
  - Bilateral increase in testicular volume
  - Occasionally cysts are seen
  - Calcifications: Microcalcifications within the tumor mass
  - Christmas tree-like appearance of multiple calcifications in syndromic LCCSCT is almost always pathognomonic for this tumor
- Metastatic workup includes:
  - Chest x-ray
  - CT pelvis and abdomen
  - Bone scan
DIFFERENTIAL DIAGNOSIS
- Always rule out precocious puberty in any child who presents with testicular enlargement and accelerated growth pattern.

- **Adult/pediatric painful mass:**
  - **Testicular trauma:** Usually blunt; contusion, rupture, usually associated hematoma.
  - **Torsion:** (testiculate, epididymal, appendicular).
  - **Henoch–Schönlein purpura** (usually no mass).

- **Adrenal rest tumors:**
  - Rhabdomyosarcoma
  - Schwannoma
  - Calcifying Sertoli cell tumor

- **Sclerosing:**
  - Adrenal rest tumors, rhabdomyosarcoma
  - Malignant fibrous histiocytoma (most common sarcoma)

- **Angioma:**
  - Fibroma, leiomyoma, hamartoma, neurofibroma

- **Mixed germ cell and stromal tumor**
  - Teratoma (1–5%)
  - Teratocarcinoma

- **Gonadal stromal tumors:**
  - Leydig tumor
  - Granulosa cell tumors

- **Germ cell tumors:**
  - Seminoma
  - Embryonal cell carcinoma
  - Carcinoma, choriocarcinoma, yolk sac carcinoma

- **Metastatic tumors:**
  - Lung
  - Prostate
  - Head and neck
  - Gastrointestinal tract

- **Bilateral LCCSTs** can gradually increase in size, block the spermatic cord, and induce gynecomastia.

- **Calcifying Sertoli cell tumors of the testes** in children and young adults are typically benign and can be treated with pharmacotherapy for symptomatic relief of gynecomastia and/or advanced puberty.

MEDICATION
- **Radical inguinal orchectomy:**
  - Used in metastatic disease, but unproven benefit.

- **Postvasectomy syndrome:**
  - Usually no mass.

- **Adrenal rest tumors:**
  - No hormonal imbalances.
  - No hereditary association.
  - Affects young adults mainly.
  - Malignancy has never been reported.

- **Testicular trauma:**
  - Usually blunt; contusion, rupture.
  - No hereditary association.

- **Incarcerated/strangulated hernia**
  - No definite recommendations can be made.

- **Adrenal rest tumors:**
  - Inhibin: Has been proposed as marker for LCCST.
  - Frozen-section biopsy confirms the diagnosis.

- **Infertility/subfertility**
  - Malignant tumors: Uncommon.

- **Metastasis:**
  - Used in metastatic disease, but unproven benefit.

- **Radiation Therapy**
  - Used in metastatic disease, but unproven benefit.

- **Aromatase inhibitors** may be an effective mode of pharmacotherapy for symptomatic relief of gynecomastia and/or advanced pubertal acceleration.

- **Surgical resection**
  - Retroperitoneal lymph node dissection: Reported approach for patient with familial syndrome.

- **LCCSCT in the setting of CNC in children and young adults are typically benign and can be treated with pharmacotherapy for symptomatic relief of gynecomastia and/or advanced pubertal acceleration**.

TREATMENT

- **BRCA1/BRCA2**
  - Breast cancer.
  - Colon cancer.

- **Testis-sparing (partial orchiectomy) inguinal**
  - In prepubertal boys, testis-sparing local excision has thought to be a more common malignancy of the testicle.

- **Radical inguinal orchiectomy**
  - Used in metastatic disease, but unproven benefit.

- **Second Line**
  - **Radiation Therapy**
    - No proven role.
  - **Chemotherapy**
    - Platinum based chemotherapy
    - Used in metastatic disease, but unproven benefit.

- **Platinum-based chemotherapy**
  - Used in metastatic disease, but unproven benefit.

- **First Line**
  - **Radiation Therapy**
    - No proven role.

FOLLOW-UP

- **Patient Monitoring**
  - **Benign tumors:**
    - Routine surveillance.

- **Malignant tumors:**
  - Imaging for metastasis.
  - Periodic screening for conditions associated with MNS is necessary in syndromic LCCST.

- **Patient Resources**

ADDITIONAL READING

CODES

- **ICD-10**
  - D29.20 Benign neoplasm of unspecified testis.
  - D29.20 Benign neoplasm of testis.
  - D29.22 Benign neoplasm of testis.

- **ICD-O**
  - 8222.2 Benign neoplasm of testis.
  - 8222.2 Benign neoplasm of testis.

CLINICAL/SURGICAL PEARLS

- Consider hereditary syndromes.

- Most Sertoli cell tumors are benign.
Testis, Teratoma, Mature and Immature

John L. Phillips, MD, FACS
Vladimir A. Valera, MD, PhD

**BASICS**

**DESCRIPTION**
- Testicular teratoma (TT) are germ cell tumors (GCTs) which form somatic tissues in varying stages of maturity (karyotype).
  - Mature (M) = well-differentiated endoderm, mesoderm, and/or ectoderm germ cell (GGC) layers
  - Immature (I) = feral or embryonal GC layers
- Most common GCT in childhood
- Adult TT: mature and immature; Consider as malignant
- Pediatric TT: mature and immature; Behave in general as benign lesions

**EPIDEMIOLOGY**
- **Prevalence**
  - 8,820 cases of testicular cancer in the US in 2014
  - 5.5 cases: 100,000 men
- **Incidence**
  - Adults: 2nd to 4th decade
  - Mature: Immature types 10:1 (1)
  - Pure teratoma (T) in 5% of adult GCTs but 35–40% of pediatric GCT
  - T found in retroperitoneum in 80% of cases
- **Pediatric TT, mature and immature:** Behave in general as benign lesions
  - Consider as malignant
  - Typically large and multinodular
  - 80% of children ≥ 2 years
  - 50% of cases

**RISK FACTORS**
- **Developmental**
  - Family history
  - 10% of patients after chemo for NSGCT (2)
- **Environmental**
  - Increased sperm counts and reduced fertility
  - Lower sperm count in patients with congenital adrenal hyperplasia
  - Increased risk of testicular cancer in patients with congenital adrenal hyperplasia
  - Increased risk of testicular cancer in patients with congenital adrenal hyperplasia

**ASSOCIATED CONDITIONS**
- **Gastrointestinal**
  - % of patients with congenital adrenal hyperplasia
  - Increased risk of testicular cancer in patients with congenital adrenal hyperplasia
  - Increased risk of testicular cancer in patients with congenital adrenal hyperplasia

**DIAGNOSIS**

**DIAGNOSTIC TESTS & INTERPRETATION**
- **Laboratory**
  - Tumor markers
  - α-Fetoprotein (AFP) (10%)
  - β-HCG (only elevated if chorio- or seminomatous elements present)
- **Imaging**
  - Ultrasonography is preferable in all cases
  - MRI is more sensitive than ultrasound
  - CT scan with and without contrast
  - PET scan not usually indicated; may have a role in the postchemotherapy setting

**DIFFERENTIAL DIAGNOSIS**
- **Benign lesions**
  - Epidermoid cysts: Common and nonmalignant
  - Fibrous pseudotumor of the testis: Benign
  - Intratesticular and extratesticular lesions:
    - Epithelial tumors: Benign
    - Malignant tumors: Benign
  - Neuroendocrine tumors: Benign
  - Other rare benign lesions: Angioma, fibroma, leiomyoma, hamartoma, carcinoid, neurofibroma
  - Malignant lesions
  - Testicular primary tumors: Benign
  - Nonseminomatous GCT

**GENERAL PREVENTION**
- **Stage patient per TNM**
- **Document tumor markers:** Important for staging
- **Document presence of nonneoplastic elements:** Important for treatment algorithms

**Pathologic Findings**
- **Large (5–10 cm), multinodular, heterogeneous (solid, cystic, mixed)**
- May contain teeth, hair, bone, cartilage
- Cystic areas mixed with solid
- Mature teratoma
  - Tissue of elements of endoderm (ep), mesoderm (eg, md), and ectoderm (eg, bone)
- Immature teratoma
  - Neuropathology with embryonic features:
    - Poorly formed cartilage
    - Primitive glandular structures
    - High grade if microscopically active
  - Dermoid cysts
    - True (benign), no atypia or mitoses
    - Keratin, hair, dermoidocyst

**DIFFERENTIAL DIAGNOSIS**
- **These are a delineation of testicular masses only. For a comprehensive listing of intrascrotal and testicular masses see Section 1: “Scrotum and Testicle Mass”**
- **Benign lesions**
  - Epidermoid cysts: Benign
  - Fibrous pseudotumor of the testis: Benign
  - Intratesticular and extratesticular lesions:
    - Epithelial tumors: Benign
    - Malignant tumors: Benign
  - Neuroendocrine tumors: Benign
  - Other rare benign lesions: Angioma, fibroma, leiomyoma, hamartoma, carcinoid, neurofibroma
  - Malignant lesions
  - Testicular primary tumors: Benign
  - Nonseminomatous GCT
  - Leukemia involving testes—tests can be a site of solitary recurrence of leukemia posttreatment
  - Treatment can be toxic with radiation, though contralateral testes should be treated as bilateral disease can be present.
  - Symptoms from invading testis: Raynaud’s phenomenon
  - Constitutional symptoms commonly present

**DIAGNOSTIC TESTS & INTERPRETATION**
- **Labor**
  - Tumor markers
  - Protin, ferritin, ceruloplasmin
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematoma
  - Testicular (testis and appendages)
  - Nonseminomatous GCT
  - Other rare benign lesions: Angioma, fibroma, leiomyoma, hamartoma, carcinoid, neurofibroma
  - Malignant lesions
  - Testicular primary tumors: Benign
  - Nonseminomatous GCT
  - Leukemia involving testes—tests can be a site of solitary recurrence of leukemia posttreatment
  - Treatment can be toxic with radiation, though contralateral testes should be treated as bilateral disease can be present.
  - Symptoms from invading testis: Raynaud’s phenomenon
  - Constitutional symptoms commonly present

**DIAGNOSIS**

**ALERT**
- Identify symptoms of metastatic disease.

**DIAGNOSTIC TESTS & INTERPRETATION**

**ALERT**
- Markers must be drawn prior to orchiectomy.

**IMAGING**
- Ultrasonography is critical in assessing for intratesticular masses; typically hypoechoic
- Microcalcification in calcified masses should be documented and followed; biopsy of biopsy is controversial, more common in Europe
- Chest x-ray or better chest CT
- Abdomen-pelvis CT scan with and without contrast (if creatinine normal)
- PET scan not usually indicated; may have a role in the postchemotherapy setting

**DIAGNOSTIC TESTS & INTERPRETATION**

**ALERT**
- Identify symptoms of metastatic disease.

**DIAGNOSTIC TESTS & INTERPRETATION**

**ALERT**
- Markers must be drawn prior to orchiectomy.

**IMAGING**
- Ultrasonography is critical in assessing for intratesticular masses; typically hypoechoic
- Microcalcification in calcified masses should be documented and followed; biopsy of biopsy is controversial, more common in Europe
- Chest x-ray or better chest CT
- Abdomen-pelvis CT scan with and without contrast (if creatinine normal)
- PET scan not usually indicated; may have a role in the postchemotherapy setting
Ongoing Care

PROGNOSIS
- Excellent with low stage & complete resection
- 95-100% cure rate in adults
- 100% cure rate in children
- Rare to poor if metastatic/complex resection
- 86-9% 2-yr survival for retroperitoneal disease only
- 40-7% 2-yr survival for retroperitoneal + multiple sites

COMPILATIONS
- Infertility
- Precocious puberty
- Post-RPLND loss of erection (infertility)
- Chemotherapy toxicity
  - Platinum: Renal
  - Bleomycin: Pulmonary toxicity and fibrosis (watch for ARDS)
  - Etoposide: Myelosuppression

FOLLOW-UP
Patient Monitoring
- Surveillance is not good option in primary teratoma because of occult GC elements in retroperitoneum
- If markers elevated, look for occult nonteratoma elements or, rarely, GI elements within teratoma.
- NCCN guidelines for teratoma after RPLND
  - Year 1–2
    - Check β-hCG (but may recur after complete resection or recur in different loci)
    - CT abdomen/pelvis baseline and q3mo
  - Year 3–4
    - β-hCG + markers q3–6mo
    - CT abdominal/pelvis q6mo
    - CT brain q4–12mo

Codes
ICD9
- 196.9 Malignant neoplasm of other and unspecified testis
- 222.0 Bening neoplasm of testis
- 752.51 Undescended testis

ICD10
- C62.20 Benign neoplasm of unspecified testis
- D29.20 Benign neoplasm of unspecified testis
- Q36.9 Undescended testicle, unspecified

Clinical/Surgical Pearls
- Teratomas are resistant to chemotherapy and radiotherapy.
- Metastatic embryonal germ cell tumor may mature into teratoma in adult males. Therefore, mature teratomas in adults should be treated aggressively.
- Infertility and mature teratomas in children are benign.
- Pure teratomas do not secrete AFP (but may harbor GI elements that do).
- Pure teratomas do not secrete A-HCG (but may harbor choriocarcinomatous or seminomatous elements that do).
- Prognosis RPLND has double the rate of teratomas than RPLND No stage I tumors.
PATHOPHYSIOLOGY

- Isochromosome 12p amplification seen in the majority of testicular cancer.
- Prevalence and Incidence
  - Incidence rate was 5.5/100,000 men per year.
  - Mortality has dropped from 5.5% today, due to improved imaging, better tumor markers, and multidrug chemotherapy.
- 95% of testicular tumors are germ cell tumors; other types are rare (see conditional conditions).
- While benign lesions can be found in the testis (see Chapter 2), all solid lesions should be considered cancer until definitely proven otherwise.

EPIDEMIOLOGY

- Prevalence
  - Median age of diagnosis was 33 (2006–2010).
- Prevalence and Incidence
  - 5.5/100,000 men per year.
  - By race/100,000: White 6.6, black 1.4, Asian men 1.9; Hispanic men 4.7.

ASSOCIATED CONDITIONS

- In 2010, in US there were 221,020 men alive with history of testicular cancer.

RISK FACTORS (2)

- History of cryptorchidism—7–10% of cases; 4–6 times more likely to develop testicular cancer.
- Seminoma is most common tumor type.
- Orchiepexy reduces relative risk (RR) from 3 to 2 if performed prior to onset of puberty.
- Family history (affected 1st-degree relative).
- History of cryptorchidism:
  - Examine both testes.
  - Examine for gynecomastia (5% of cases).
- History of infertility:
  - Systemic symptoms: Weight loss; abdominal pain/discomfort; fevers; mastodynia or other changes in secondary sex characteristics.
  - Local symptoms: Change in testicular size or texture; testicular pain (uncommon).

DIFFERENTIAL DIAGNOSIS

- Benign lesions
  - Nongerm cell tumors (5–7%): Leydig cell tumors: 2–3% of tumors; not fixed to scrotum, and size of lesion correlates with disease bulk.
  - Invasive cancer of the testis: Malignant germ cell tumors: These are a delineation of testicular masses only. For a complete listing of intracapsular and testicular masses see Section I “Scrotum and Testicle Mass”.
- Nonspecific marker for GCT
  - Elevated in 40–60% with testis cancer; 100% of testis cancer.
  - Half-life: 1 day.
  - Half-life: 24–36 hr.
  - Half-life: 24–36 hr.
- Elevated in 40–60% with testis cancer; 100% of testis cancer.
  - Half-life: 5–7 days.
  - Produced by yolk sac tumors, embryonal cell carcinoma, and teratocarcinoma.
  - Not produced in pure seminoma or pure choriocarcinoma. If AFP elevated in case of pure seminoma, 70% will be choriocarcinoma.
  - Prognosis for pure choriocarcinoma is poor.
- Nonspecific marker for GCT
  - Elevated in 20% of low stage and 50% of high-stage GCT.
  - Half-life: 5–7 days.
  - Serum and urine estrogen may be elevated in Leydig cell tumors.

DIAGNOSIS

- HISTORY
  - Local symptoms: Change in testicular size or texture; testicular pain (uncommon).
  - Systemic symptoms:
    - Weight loss; abdominal pain/discomfort; fevers; mastodynia or other changes in secondary sex characteristics.
    - History: Cryptorchidism, infertility, orchiepexy.
- PHYSICAL EXAM
  - Check all lymph nodes, including supraclavicular lymph nodes.
  - Check all lymph nodes.
  - Check all lymph nodes.
- DIAGNOSTIC TESTS & INTERPRETATION
  - Tumor markers obtained prior to orchiectomy.
  - Lobectomy of testis—testis can be a site of sanctuary for testicular cancer. Biopsy can be utilized to confirm diagnosis in a patient with history of leukemia.
  - Treatment can be tests sparing with radiation, though contralateral testis should be treated as bilateral disease can be present.

TESTIS, TUMOR AND MASS, ADULT, GENERAL CONSIDERATIONS

Srinivas Vourganti, MD
Allan D. Sefer, MD, FACS
SURGERY/OTHER PROCEDURES

Radical orchectomy:  - Indicated in patients with stage I and II NSGCT.  - Follow-up similar to stage IIA seminomas.  - Frequency of follow-up is based on initial stage and cell type and the response to therapy.

SECOND LINE
High-dose chemotherapy with autologous bone marrow transplantation in patients with residual disease and/or recurrent disease or failure, enrollment in a clinical trial.

COMPLICATIONS
- Intensity:  - Increased risk of secondary malignancies in patients undergoing chemotherapy or radiation

FOLLOW-UP

Patient Monitoring
- In patients who undergo RPND:  - Serial monitoring with chest x-ray, physical exam, and tumor markers.  - RPND is rare, so imaging of this region is not usually needed.
- Follow-up depends upon initial stage and cell type of primary tumor and response to therapy.
- In patients who did not undergo RPND:  - Follow-up similar, serial monitoring of retroperitoneum using CT scanning.
- Frequency of follow-up is based on initial stage and cell type and the response to therapy.

Patient Resources
- American Cancer Society: http://www.cancer.org/cancer/testicularcancer/index

CLINICAL/SURGICAL PEARLS
- Increased risk of malignancy in patients with history of cryptorchidism and family history of testis cancer.
- Ultrasound should be performed to resolve any concerns of abnormal scrotal swelling.
- Initial diagnosis of radical orchectomy using an inguinal approach to avoid scrotal violation.
- All testis masses in adults should be considered malignant until proven otherwise.
RISK FACTORS

Incidence

- 0.5–2 per 100,000 children/yr
- 25–30% of pediatric tumors are malignant (2).
- Testis accounts for 2% of pediatric tumors.

The most common causes of painless scrotal swelling in a child include hernias, hydroceles, varicocele, and scrotal wall swelling.

- Tests-SPG of 15% of pediatric tumors.

Epidemiology

Prepubertal testicular tumors in children are much more often benign than the postpubertal tumors which are more often malignant.

Must differentiate a true testicular tumor or mass from paratesticular and scrotal masses.

- The most common causes of painless scrotal swelling in a child include hernias, hydroceles, varicocele, and scrotal wall swelling.
- Tests-SG of 15% of pediatric tumors.

RISK FACTORS

- Risk factors for GCTs:
  - Past personal history
  - Family history
  - Gonadal stromal tumors: 10–15% of cases (3), leukemia: <2%, cystic dysplasia: <1%

- Prevalence

GENERAL CONSIDERATIONS

- **YST (also called endodermal sinus tumor):**
  - AFP elevated in 80% of YST, and normally elevated in a neonate (physiologically).
  - AFP half-life is 5–7 days.
  - Elevated after orchectomy implies metastatic disease.
  - Yolk sac elements stain positive for AFP.
  - β-hCG produced by syncytiotrophoblast indicates a mixed GCT.

- **Gonadoblastoma:**
  - Most common tumor in disorders of sexual development; germ cell component prone to malignant degeneration.
  - Seminomas and mixed GCT rare in prepubertal children.

- **Gonadal tumors (3):**
  - Leydig cell tumor:
    - Peak age: 4–5 yr.
    - Decreased testosterone production with normal LH.
  - Differential diagnosis includes pituitary lesions, Leydig cell hyperplasia, CAH based on hormonal production.
  - Reinecke crystals classically described in adults.
  - Rare in children on histology.
  - Malignancy not reported in Leydig cell tumors in children.
  - Sertoli cell tumor:
    - Peak age: <4; most not hormonally active.
    - May serve as a sanctuary site of these tumors.
    - AFP elevated in a neonate (physiologically).
  - Granulosa cell tumor:
    - Rarely metastasizes.
    - Testes tumor of adrenogenital syndrome:
      - Benign, suppressible with glucocorticoids.
    - Gynecomastia when hormonally active.
      - Peak age: 4; most not hormonally active.
      - AFP elevated in 80% of YST, and normally elevated in a neonate (physiologically).
      - β-hCG produced by syncytiotrophoblast indicates a mixed GCT.

PHYSICAL EXAM

- Scrotal asymmetry.
- Abnormality intratesticular vs. intratesticular vs. paratesticular.
- Diffusely enlarged testicle or palpable nodularity in the testicle.
- Does not transilluminate (solid).
- Inguinal canal and cord structures are usually normal in a boy with a testicular tumor.
- Signs of precocious puberty.

DIAGNOSTIC TESTS & INTERPRETATION

- Serum markers AFP and β-hCG.
- Obtain prior to orchiectomy in all patients with a testicular mass.
- Marked AFP elevations present in neonates; may be detectable up to 8 mo of age.
- Serum testosterone, LH, and FSH levels if a gonadal mass is suspected.

Imaging

- Scrotal ultrasound (US)
  - Differentiates intratesticular vs. extratesticular.
  - Does not differentiate benign from malignant.
  - Paratesticular rhabdomyosarcoma (PT-RMS): Does not differentiate benign from malignant.
  - Hypervascular, solid extratesticular mass.
  - Often large, testicle not seen on US.
  - Metastatic disease seen as small, multiple nodules in the retroperitoneum.
  - Metastatic disease seen on US.
  - Normal in a boy with a testicular tumor.
  - Staging:
    - Stage 1: Limited to testis, markers normalize according to half-life. No radiologic evidence of metastatic disease.
    - Stage 2: Transcrotal orchectomy or tumor rupture during orchectomy, persistent elevated markers, residual disease in scrotum or disease on pathology >5 cm from testicular cord margin.
    - Stage 3: Nodes >4 cm, no visceral or distant disease.
    - Stage 4: Distant metastases.
  - Postpubertal GCTs staged and managed according to adult testicular cancer guidelines.

ASSOCIATED CONDITIONS

- Disorders of sexual development with a dysgenetic testis (e.g., DSD).
- Marked AFP elevations present in neonates; may be detectable up to 8 mo of age.
- Serum testosterone, LH, and FSH levels if a gonadal mass is suspected.

DIAGNOSTIC PROCEDURES/SURGERY

- All suspicious testicular and paratesticular lesions should be approached inguinally.
- Prepubertal patients with a primary testicular lesion and normal tumor markers may be considered for tests-sparring surgery (TSS).
- Such approaches require intraoperative assessment including immediate frozen-section analysis to ensure complete resection.
- If frozen-section reveals GCT elements or concern for incomplete resection, radical orchidectomy should be performed.
- Intraoperative US may be helpful.
- Prepubertal patients with a normal contralateral testicle should undergo radical inguinal orchidectomy.
- Paratesticular lesions consistent with malignancy should be managed with radical inguinal orchidectomy.

BASICS

- Important to distinguish prepubertal "pediatric" testes tumors from the postpubertal "adolescent" testes tumors (1).
- Prepubertal testicular tumors in children are much more often benign than the postpubertal tumors which are more often malignant.
- Must differentiate a true testicular tumor or mass from paratesticular and scrotal masses.
- The most common causes of painless scrotal swelling in a child include hernias, hydroceles, varicocele, and scrotal wall swelling.

PATHOPHYSIOLOGY

- GCTs typically develop from a precursor lesion, which, in turn, appears to develop from arrested primordial germ cells or gonocytes.
- Teratoma: Monodermal (epidermoid/cyst) or multiple histologic types present.
- Normal adult testicular neoplasm include tubular ectasia of the rete testis, inflammation, and hematoma.
- Marked AFP elevations present in newborn; may be detectable up to 8 mo of age.
- Serum testosterone, LH, and FSH levels if a gonadal mass is suspected.

TESTIS, TUMOR AND MASS, PEDIATRIC, GENERAL CONSIDERATIONS

Nicholas G. Cost, MD
Paul H. Noh, MD, FACS, FAAP
Pathologic Findings

- GCTs
  - Teratoma: Consists of elements of at least 2 of the 3 germ cell layers of endoderm, mesoderm, and ectoderm.
  - YST: Epithelial cells that form glandular and ductal structures arranged in columns, papillary projections, or solid islands within a primitive mesenchymal stroma. The cells have poorly defined cell borders and vacuolated cytoplasm with glycogen and fat.
  - Seminoma: Islands or sheets of relatively large cells with clear cytoplasm and densely staining nuclei.
  - Embryonal carcinoma: Predominantly epithelial cells arranged in glands or tubules. Cell borders indistinct, cytoplasm pale or vacuolated, and nuclei rounded with coarse chromatin.
  - Choriocarcinoma: Distinct cell types must be demonstrated to satisfy the histologic diagnosis of choriocarcinoma. Syncytiotrophoblasts and cytotrophoblasts.
  - Granulosa cell tumors: Must have 3 elements: Sertoli cells, interstitial tissue, and germ cells.

- Stromal tumors
  - Leydig cell tumors: Uniform, closely packed cells with clear cytoplasm and densely staining nuclei.
  - Sertoli cell tumors: Epithelial elements resembling Sertoli cells and varying stroma.
  - Granulosa cell tumors: Characteristic Call-Exner bodies may be identified, consisting of PAS-positive material similar to that seen in the basement membrane of the tubules.

DIFFERENTIAL DIAGNOSIS

- Painful childhood testicular masses:
  - Epidermoid and squamous cell carcinomas
  - Inguinal hernia
  - Varicocele
  - Henoch–Schönlein purpura (usually no mass)
  - Epididymitis/orchitis; bacterial, mumps

- Other causes of testicular swelling or pain and testicular tumors:
  - Rhabdomyosarcoma (RMS) (bimodal age 3–4 and adolescence)
  - Polyorchidism
  - Lipoma of the cord
  - Hernia
  - Hydrocele, primary or due to trauma, torsion, tumor, epididymitis; hydrocele of cord
  - Fibrous pseudotumor of the tunica albuginea
  - Cystic dysplasia of the testis
  - Adrenal rest tumors
  - Adenomatoid tumor of testis or epididymis
  - Torsion (testicle, testicular or epididymal appendage); more common after puberty
  - Henoch–Schönlein purpura (usually no mass)
  - Epididymitis/orchitis; bacterial, mumps

- Germ cell tumors: Characteristic Call-Exner bodies may be identified, consisting of PAS-positive material similar to that seen in the basement membrane of the tubules.

- Embryonal carcinoma: Malignant epithelioid cells, interstitial tissue, and germ cells

- Choriocarcinoma: Syncytiotrophoblasts and cytotrophoblasts

- Teratoma: Contain elements of at least 2 of the 3 germ cell layers of endoderm, mesoderm, and ectoderm.

- Embryonal carcinoma: Malignant epithelioid cells, interstitial tissue, and germ cells

- Choriocarcinoma: Syncytiotrophoblasts and cytotrophoblasts

- Teratoma: Contain elements of at least 2 of the 3 germ cell layers of endoderm, mesoderm, and ectoderm.

TESTOSTERONE REPLACEMENT THERAPY, GENERAL PRINCIPLES

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

Basics

Description
Hypogonadism is the clinical syndrome associated with low serum testosterone (T).

- Can occur in early life (eunuchoid), although most commonly seen in aging males.
- Late-onset male hypogonadism may also be referred to as andropause.
- Androgen deficiency in the aging male (andropause) or androgen deficiency syndrome.

Epidemiology
Incidence
- Prevalence: 2–4 million men in U.S.

- Age-related decline (“andropause”)
- Increased serum sex hormone binding globulin
- Dampening in the amplitude of circadian release of T
- Decreased testicular responsiveness to LH
- Overall 5.6–38.7% men are affected, depending on study.

Risk Factors
- Medical conditions (chronic lung disease, chronic renal failure, anorexia nervosa, depression, HIV
- Hypothyroidism (which suppresses the pituitary, testes, adrenal, prostate)
- Increased body fat (visceral obesity)
- Medications (GnRH agonists/antagonists, androgen antagonists, estrogen, opiates, lithium, steroids, amiodarone, thiazide diuretics, omeprazole)
- Low protein diet

Genetics
- Pathologic Findings

Pathophysiology
- At age increases, there is:
  - Decreased number of Leydig cells within the testicle (site of T production)
  - Decreased testicular responsiveness to LH
  - Diminution in the amplitude of circadian release of T
- Increased serum sex hormone binding globulin (SHBG): Concentration of T is therefore less bioavailable (functionally active) T

Associated Conditions
- Metabolic syndrome (obesity, hypertension, diabetes)
- Impaired fasting glucose/insulin resistance/diabetes mellitus type II (OSSA)
- Asthma/chronic obstructive pulmonary disease/obstructive sleep apnea (OSA)
- Disossemiosis

General Prevention
No

History
- Low energy level/daytime sleepiness (2)[B]
- Decreased sexual interest/erectile dysfunction (2)[A]
- Frequent dyshydra (ED)/voidance of spontaneous erections/erectile dysfunction (2)[A]
- Decreased motivation/creativity
- Hot flushes/sweats
- Loss of muscle/massive obesity
- Visual field defects

- Several validated questionnaires to screen for T deficiency have been developed, but are unreliable with low specificity (1)[C]

Physical Exam
- May not be contributory (2)[B]
- Small testicular size/soft consistency (2)[B]
- Hair distribution and pattern (2)[B]
- Gynecomastia (2)[B]
- Digital exam (2)[B] to rule out palpable prostate abnormality

Diagnostic Tests & Interpretation

Lab
- Total serum T (best before 11:00 am) (1)[A]
- Free T
- Bioavailable T
- No universally accepted lower limit of normal serum T
- It is generally agreed that serum T > 12 nmol/L (350 ng/dL) does not usually need replacement (2)[A]
- If T < 8 nmol/L (230 ng/dL), replacement is typically beneficial (2)[B]

- FDA research trial definition: Hypogonadism is total serum T levels of < 300 ng/dL.
- Serum albumin
- SHBG
- If secondary hypogonadism is suspected:
  - Serum prolactin, Serum gonadotropines (LH; FSH)

Imaging
- Imaging (MRI, CT) if prostatomegaly suspected
- Dose scan for the assessment of bone mineral density (note the risk for osteoporosis/osteopenia (1)[B]

Diagnostic Procedures/Surgery
- No

Pathologic Findings
- No

Differential Diagnosis
- Acute critical illness (surgery, head trauma)
- Age-related decline (“andropause”)

- Alcoholism
- Chronic; illness/failures; chronic renal failure; hypertension; hyperlipidemia; diabetes; sleep apnea; obesity, anorexia nervosa, depression, HIV
- Hematologic (sickle cell disease, thalassemia)
- Hemochromatosis of the pituitary, Leydig cells
- Hypothyroidism (hypothyroidism, hypopituitarism
- Kallmann, Klinefelter, or Nelson syndrome
- Medications: GnRH analogues/castration, glucocorticoids, androgens, estrogens, progestins (eg, megestrol), chronic opioids, marijuana (controversial)

- Pituitary infusions, infarction, trauma, radiation (aberrant TRH production)
- Pituitary tumors, macroadenomas, hyperprolactinema

- Syndrome: Prader–Willi and Sertoli only

- Testicular failure (primary): Congenital or acquired anemia, hypothyroidism, mumps orchitis, radiation therapy, chemotherapy
- Testicular tumors

Treatment

General Measures
- Treatment is warranted for men with clinical symptoms associated with objective biochemical findings of low T (2)[C]
- In the context of significant symptoms and normal or borderline T levels, a trial of TRT is acceptable with appropriate follow-up to ensure improvement in symptoms (2)[C]. If no improvement is noted, further workup to delineate cause is warranted

- In the presence of visceral obesity, weight loss through regular exercise and low-calorie intake is recommended (2)[A]
- Appropriate glycemic, blood pressure, and lipid management is recommended
- TRT contraindications include:
  - Known prostate cancer (absolute)
  - Known breast cancer (absolute)
  - Unexplained prostate-specific antigen (PSA) elevation/suspicious DRE finding (absolute)
  - Severe lower urinary tract symptoms (LUTS) associated with BPH
  - Enlarged prostate (50 or greater) (2)[B]
  - Uncontrolled/poorly controlled heart failure
  - Unintended OSA, although no scientific evidence exists demonstrating a direct causal relationship between T and OSA
  - Men seeking fertility

- Improvement is expected in:
  - Reduction of body fat/massive obesity (2)[A]
  - Increase in fat-free mass/muscule strength (1)[A]
  - Insulin resistance/diabetes control in men with DM II (2)[A]
  - Bone mineral density at lumbar spine (1)[A]
  - Hypogonadism with sexual desire/ED/delayed ejaculation (2)[B]

- Considerations in the elderly male: The American Geriatrics Society (AGS) lists T as a medication to generally avoid in older adults because of potential for cardiac problems and men with personal history of prostate cancer.

- TRT agents/options outlined below

- Testicular tumors, macroadenomas, hyperprolactinema

- Syndrome: Prader–Willi and Sertoli only

- Testicular failure (primary): Congenital or acquired anemia, hypothyroidism, mumps orchitis, radiation therapy, chemotherapy
- Testicular tumors

First Line
- Buccal (strimore) 30 mg Tbl 3 times/day
- Dose: 30 mg BD
- Avoids 1st pass effect of hepatic metabolism
- Apply to gum over incisor; do not chew/swallow

- Transdermal (Androgel): Apply to nonshaved skin
- Dose: 5–10 mg/g twice/day, 3 times/day
- Avoid: Brewery, alcohol, hot showers, hot tubs

- Topical agents: Interpersonal transfer possible and should be avoided, especially for women and children

- Gels should be dry before putting on clothes over application site; delay washing

- Brand names provided to avoid patient confusion; see FDA label for details

Medication
**TESTOSTERONE REPLACEMENT THERAPY, GENERAL PRINCIPLES**

- Transdermal gels; product-specific dosing; apply clean dry; Shouder, upper arm, abdomen
- (AndroGel 1%)
- Dosage: Topical daily 5–10 g (max)
- (AndroGel 1.62%)
  - Dosage: Topical 2 pump activations or 40–50 mg patch, adjust from 1 activation 20–25 mg or single 20.25 mg patch, 81 mg (max)
  - Intranasal 10 mg/15 mg per application; apply to inner nasal area only
- Dosage: Scott 4 pump activations (30 mg) QAM; adjust 1–7 pump activations (10 mg–70 mg daily), 70 mg max
- (Testim 1%) 50 mg/1.5 g gel; 50 mg repeat dose taken; apply shoulder or upper arm
- Dosage: Scott 5–10 g patches MAX
  - Transdermal solution
    - (Oseso 1%) 30 mg/5.5 mL of solution
    - Dosage 60 mg T CI pump = 30 mL of T solution to each arm daily; adjust based on levels
  - IM short-acting formulations may be associated with fluctuations in serum T (subcutaneously 2–6 d after injection, subdermal 10–14 d after injection) which may be associated with symptom fluctuation
  - T cypionate (Depo-Testosterone) 200–400 mg IM every 3–4 wk or 100–150 mg every 2 wk preferred
  - T enanthate (Biolostat) 100–400 mg IM every 4 wk or 100–150 mg every 2 wk preferred
  - Nandrolone decanoate: 100–300 mg IM monthly until puberty development occurs
- T implant
  - Pellets (Testopel) (735 mg) 150–450 mg SC implant every 3–4 wk or 2 pellets for each 25 mg T required weekly; in upper buttock with local anesthetic
  - Local symptoms such as pain, bleeding
  - Pellet infection and extrusion (up to 10%)
  - Parenteral T undecanoate (Avodox): 750 mg IM (3 mL) Initially, at 4 wk, then 750 mg every 10 wk
  - T gel (Testim) 2 pump activations or 11 (T10 testosterone) one in each nostril 7D (total 33 mg/day)
- 1 formulations outside the US:
  - Oral T undecanoate: 40–80 mg PO with meals BID to TID
  - T–in–adhesive matrix patch: 2 patches (4.8 mg Tiday) applied every 2 days
  - T gel 2% 3–4 g (60–80 mg) T applied to abdomen or both thighs daily

**SECOND LINE**

- Any agent from the first line medication can be used as second line if the product is ineffective or there are practical use issues with an individual patient

**SURGERY/OTHER PROCEDURES**

- Insertion of subdermal T pellets (see above MEDICATION First line)

**ADDITIONAL TREATMENT**

- **Radiation Therapy**

**ADDITIONAL THERAPIES**

- There may be therapeutic synergism with combined TRT and phosphodiesterase-5 inhibitors in men with low T and ED (2E)
- Other forms of androgen therapy include the usage of dehydroepiandrosterone (DHEA), dihydrotestosterone (DHT), although their use has not been proven effective (2E)
- **Human chorionic gonadotropin (hCG)** may preserve spermatogenesis in young men with hypogonadism (1B) (See Section “Testosterone, Decreased Hypogonadism”)
- Antiandrogens and aromatase inhibitors may raise endogenous T in secondary hypogonadism if the hypothalamic–pituitary–testicular axis is intact
- Selective androgen receptor modulators (SRMs) may have a role in hypogonadism

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- There are no alternative therapies that will cure low T. Some stress management techniques can relieve the stress and anxiety associated with hypogonadism: yoga, meditation techniques, emotional support/counseling, healthy lifestyle (nutritious diet, active exercise, adequate rest)

**ONGOING CARE**

**PROGNOSIS**

- Goal is for the restoration of serum T within normal lab limits; supraphysiologic levels should be avoided (2E)
- Target serum T should be 40–70% of upper limit of normal serum T (2E)
- There is no evidence of benefit for maintaining a diurnal rhythm of serum T (2E)

**COMPLICATIONS**

- Enlarged prostatic hyperplasia
- Erythrocytosis; gynecomastia; fluid retention
- Other than prostate cancer, no other malignancies have been reported

**FOLLOW-UP**

- Patient Monitoring
  - Clinical and biochemical verification of treatment effect should occur 1–6 mo after initiating TRT (depending on TRT modality) (1C)
  - Repeat assessment of serum T parameters
  - Dosing may be adjusted if TRT suboptimally effective
- Monitor hematocrit 3, 6, and 12 mo after initiating TRT, then annually (1A)
- Monitor prostate health (DRE/PSA) 3, 6, and 12 mo after initiating TRT, then annually (1A)
- In men with known unresponsive or metastatic prostate cancer, bone mineral density should be verified after 6, 12, or 24 mo of TRT (1C)
- Monitoring lipid and glomseria is not routinely required for safety but should be done as part of general health maintenance

**CODES**

- 107.9 Other subclinical hypogonadism
- 107.8 Androgen deficiency in male hypogonadism

**CLINICAL/SURGICAL PEARLS**

- Treatment is usually indicated for men with both symptoms and lab evidence of low serum T.
- The risks and benefits of each TRT modality should be thoroughly discussed.
- Post TRT initiation, patient monitoring for treatment effect, biochemical resolution, and development of adverse effects is critical.
- Patients who have completed prostate cancer treatment for localized disease cancer treatment may cautiously be initiated on TRT in certain circumstances.
TESTOSTERONE, DECREASED (HYPOGONADISM)
Philip T. Zhao, MD
Allen D. Seftel, MD

BASICS
DESCRIPTION
Hypogonadism is the clinical syndrome associated with low serum testosterone (T).

- Can occur in early age (early onset), although most commonly seen in aging males.
- Late-onset male hypogonadism may also be referred to as andropause, androgen deficiency in the aging male, or androgen deficiency syndrome.
- Usually associated with impaired sperm production, or with an isolated impairment of sperm production or function with normal T production.

- T is essential for:
  - Normal sexual function, growth and development of male sexual organs, and maintenance of male secondary sexual characteristics.
  - Normal levels and function result in:
    - Enhanced libido, increased energy, and production of RBCs; osteoporosis protection.

In utero hypogonadism:
- Ambiguous genitalia, normal female genitalia, microphallus, pseudovaginal perineoscrotal hypospadias, bifid scrotum, cryptorchidism.

Prepubertal hypogonadism:
- Delayed puberty, microphallus, small testes, no male hair pattern, disproportionately long arms/legs, high-pitched voice, poor muscle mass.

Postpubertal/adult hypogonadism:
- Lack of libido, erectile dysfunction (ED), hot flashes/sweats, gynecomastia, spermarche, infertility (azoospermia), increased body fat/BMI, osteopenia/osteoporosis, hypercholesterolemia.

EPIDEMIOLOGY
Incidence
- N/A

Prevalence (1)
- 2–4 million men in US; Hypogonadism increases with age.
  - Overall 5.6–38.7% men are affected, depending on study.
  - 6th decade: 12%; 7th: 19%; 8th: 29%; 9th: 49%.

RISK FACTORS
- Testicular trauma/orchiectomy.
- Medications
  - Decreased T production: Dopamine antagonists, corticosteroids, ethanol, ketoconazole, GnRH analogues/antagonists.
  - Decreased conversion of T to dihydrotestosterone (DHT), see Reductase inhibitors.
  - Androgen receptor blockade: Flutamide, spironolactone, cyproterone, finasteride.
  - Infections (mumps orchitis, HIV).
  - Medical conditions:
    - Iron toxicity to pituitary gonadotrophs, autoimmune diseases, etiologic renal disease (ESRD), uremia, histiocytosis X, pituitary apoplexy.
    - Myotonic dystrophy.

Genetics
- Klinefelter syndrome.
- Kallmann syndrome; mutation in Dax-1.
- Laurence–Moon–Bardet–Biedl syndrome.
- Prader–Willi syndrome.
- Y chromosome microdeletion.
- Congenital androgen resistance/insensitivity.
- Alstrom, Rud, Bloom syndromes; mutations in leptin.

PATHOPHYSIOLOGY
- T is regulated by the hypothalamic–pituitary-testicular axis.
- Gonadotropin-releasing hormone (GnRH) neurons originate in the olfactory placode and migrate through the cribriform plate of the ethmoid to localize in the hypothalamus.
- GnRH pulse amplitude and frequency activate intracellular signalling mechanisms, which results in differential gene expression of the 2 subunits forming LH and FSH.
- LH stimulates Leydig cells to produce T.
- Feedback inhibition by T on the hypothalamus and pituitary maintains hormonal balance.
- FSH stimulates Sertoli cells to support spermatogenesis and sperm inhibition, which provides feedback on the pituitary.
- Week-long night/day shift work does not seem to change T levels.
- T levels decrease 0.8–1.6% per year in men aged 40–70.

ASSOCIATED CONDITIONS
- Increased risk for developing type 2 diabetes mellitus, metabolic syndrome, cardiac events, and a general reduction in survival.
- Impact on cardiac events is controversial with most publications supporting a protective effect of “normal” T levels.

GENERAL PREVENTION
- Screening: The Endocrine Society in US recommends against screening for androgen deficiency in the general population.

DIAGNOSIS
HISTORY
- Development:
  - General abnormalities (eg, hypospadias, microphallus, cryptorchidism), delayed sexual development/growth, need for hormone therapy, family history of delayed puberty or reproductive disorders; psychological impact of delayed puberty or growth, difficulty in school or learning disability, inability or reduced ability to smell.

- Sexual function:
  - Poor erections; reduced spontaneous, nighttime, morning erections; inability to perform sexually; decreased sexual activity; inability to father children despite uncorrected sexual relations (> 1 yr); small or shrinking testes.
Definitions of T levels and hypogonadism are the Food and Drug Administration (FDA) uses a cutoff value of 300 ng/dL to define hypogonadism. There is no consensus among specialists (endocrinologists, urologists, pathologists) as to what lab values define a “low” T level. Society definitions of T levels and hypogonadism are summarized in Section II: “Hypogonadism, Society Definitions”.

**Lab**

- Testicular size: palpation
- Testosterone: serum
- Testosterone precursors: DHEA-S
- Testosterone metabolites: estradiol

**EXTERNAL GENITALIA**: Testes and phallus

- Small, firm suggests Klinefelter syndrome
- Soft and atrophic but normal sized suggestive of hypogonadism

**BRAIN FUNCTION**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**BONE FUNCTION**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**Gastrointestinal functions**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**Cardiovascular function**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**Respiratory function**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**Integumentary system**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**Musculoskeletal system**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**Hypothalamic-pituitary-gonadal (HPG) axis**

- Decreased muscle bulk/strength; reduced physical activity or performance; broad or elongated gait; poor coordination and memory

**Differential diagnosis**

- Hypogonadotropic hypogonadism (primary): Inadequate stimulation of gonadotropin release by the hypothalamus
- Hypergonadotropic hypogonadism (primary): Gonadal failure (chemotherapy or radiotherapy)
- Hypogonadotropic hypogonadism (secondary): Inadequate stimulation of gonadotropin release by the hypothalamus

**Pathological findings**

- Testicular biopsy: Klinefelter syndrome
- FSH and LH: Kallmann syndrome
- Androgen receptor assay (genetic testing):
  - Small testes: Klinefelter syndrome
  - Large testes: Pretibial myxedema, pseudohyppoparathyroidism

**Diagnostic procedures/surgery**

- MRI: Testicular tumor
- Biopsy: Testicular mass
- Ultrasound: Testicular mass

**Treatment**

- Avoid T replacement in a man with infertility seeking to regain fertility.

**General measures**

- General well-being; reduced sexual desire, interest, and motivation (fatigue); poor energy/vitality; excessive fatigue; poor motivation and initiative, passivity, low self-confidence/self-esteem; depressed mood; irritability; difficulty sleeping; hot flashes/sweats, poor concentration and memory

**Physical examination**

- External genitalia: Testis and phallus
- Testes volume
- Measure with a Prader orchidometer (normal adult 15–25 mL)
- ≤ 6 mL: characteristic of prepubertal hypogonadism
- Soft and atrophic but normal sized suggestive of prepubertal hypogonadism
- Small, firm suggests Klinefelter syndrome
- Genital ambiguity, hypoplastic/absent penis

**Diagnostic tests & interpretation**

- There is no consensus among specialists (endocrinologists, urologists, pathologists) as to what lab values define a “low” T level.
- The Food and Drug Administration (FDA) uses a cutoff value of 300 ng/dL to define hypogonadism for clinical trial development and enrollment.
- Society definitions of T levels and hypogonadism are summarized in Section II: “Hypogonadism, Society Definitions”.
- Total T concentrations are affected by alterations in sex hormone binding globulin (SHBG), and T levels may be suppressed sufficiently with illness, certain medications, and some nutritional deficiencies.
**MEDICATION**

## First Line
- **Buccal** (Sialol) 30 mg Titrat-system
  - Dose: 30 mg BID
  - Avoid 1st pass effect of hepatic inactivation
- **Transdermal** (Androderm). Apply to non-scrotal skin (back, abdomen, upper arms, thighs); avoid bony prominence; delivers 2-4 mg/patch
  - Dose: Based on patch; start one 4 mg/patch/24 h; adjust to 1 or more patch combinations for desired effect
- Skin irritation may be noted; remove for MRI
- **Transdermal** pain; product-specific dosing; apply deep dry: Shoulder, upper arm, or abdomen
  - (AndroGel 1%)—Doses: Topical daily 5-10 g (24 h)
  - (AndroGel 1.62%)—Doses: Topical 2 pump activations or 40-55 mg pack; adjust from 1 activation 25-25 mg or single 25-25 mg packs; 81 mg (24 h)
  - (Fortesta) 10 mg 10.5 mg/g per patch; apply to inner thigh area only
  - Dose: Start 4 pump activations (80 mg QAM); adjust 1-2 pump activations (50-70 mg daily; 70 mg max)
- (Dector) 10 g 50 g 1-5 g gels: 50 mg/g dose tube; apply shoulder or upper arm
  - Dose: Topical 5-10 g/2 tubes MAX
- **Transdermal solution**
  - (Aventen) 30 mg/1.5 mL solution
  - Dose 60 mg T (1 pump) = 30 mg of T solution to each area daily; adjust based on levels
- RA short-acting formulations, may be associated with fluctuations in serum T (endocrinologic fluctuations)
  - (Gelone; Testosterone) 200-400 mg IM every 3-4 wk or 100-150 mg every 2 wk preferred
  - 1 anectrate (Deltrostib) 100-400 mg IM every 4 wk or 100-150 mg every 2 wk preferred
  - Pentaject: 50-100 mg IM agent monthly, or 25-50 mg every 2 wk, increase to 50-100 mg every 4 wk and then adult dose over 2-4 yr or until pubertal development occurs

## Second Line
- **T implant**
  - (Omipact) 2 pellets (15 mg/packet) 150-450 mg SC implant every 3-6 mo
  - 2 pellets for each 25-25 mg required weekly, in upper buttock with local anesthesia
  - Local symptoms such as pain, bleeding
  - Pelvic infection and erosion (up to 10%)
  - T nasal gel (Nasltest 2 pumps each nostril; 111 mg testosterone) once in each nostril 110 mg total (113 mg/day)
  - T formulations outside US:
    - Oral T undecanoate: 40-80 mg PO with meals IND to TID
    - Parenteral T undecanoate: 1,000 mg IM initially, at 6 wk, then 1,000 mg every 10-14 wk; long lasting
    - T in-adhesive matrix patch: 2 patches (4.8 mg T) applied every 2 days
    - T gel 2%; 3.4-4.60-80 mg of T) applied to abdomen or both inner thighs daily

### Second Line
- Any of the agents noted as first line can be potentially used a second line alternative agents

## SURGERY/OTHER PROCEDURES
### Pituitary adenoma; Transsphenoidal resection
- **ADDITIONAL TREATMENT**
- **Radiation Therapy**
  - GnRH: 5-25 ng/kg SQ every 2 hr by programmable infusion pump for 6-12 mo or longer
  - FSH/human menopausal gonadotropin (hMG), LHRH agonists, recombinant human FSH (rhFSH): After 6-12 mo of hCG treatment alone
  - Human chorionic gonadotropin (hCG): 500-2,000 IU given SQ 2-3x weekly to maintain serum T levels within the normal range for 6-12 mo
  - Addition to KCS to stimulate sperm production: human chorionic gonadotrophin (hCG): 500-2,000 IU given SQ 2-3x weekly to maintain serum T levels within the normal range for 6-12 mo
  - Added to KCS to stimulate sperm production: FSH/human menopausal gonadotropin (hMG), human FSH (FSH), recombinant human FSH (rHMG)

### Additional Therapies
- **if Hypogonadotropic**: May provide
  - supplemental hormone replacement therapy to stimulate testicular production of androgens
  - Initially stimulate T and sperm production:
    - Human chorionic gonadotrophin (hCG): 500-2,000 IU given SQ 2-3x weekly to maintain serum T levels within the normal range for 6-12 mo
  - Addition to KCS to stimulate sperm production
    - FSH/human menopausal gonadotropin (hMG), human FSH (FSH), recombinant human FSH (rHMG)

### Additional Therapies
- **If Hypogonadotropic**: May provide
  - supplemental hormone replacement therapy to stimulate testicular production of androgens
  - Initially stimulate T and sperm production:
    - Human chorionic gonadotrophin (hCG): 500-2,000 IU given SQ 2-3x weekly to maintain serum T levels within the normal range for 6-12 mo
  - Addition to KCS to stimulate sperm production
    - FSH/human menopausal gonadotropin (hMG), human FSH (FSH), recombinant human FSH (rHMG)

### Ongoing Care
- Radiation therapy to restore T levels to the normal range by adjusting dosage of medication and improve symptoms of hypogonadism (4)
- **COMPLICATIONS**
  - **Hypogonadism**: (5)
  - Metabolic syndrome: Anemia, increased fasting blood sugar, increased triglycerides, increased cholesterol, increased body fat
  - Appetite changes (increased or decreased)
  - Balance problems
  - Body hair loss
  - Dry eyes
  - Edema or leg pain
  - Fatigue
  - GI and/or respiratory disturbances
  - Dry mouth
  - Hot flashes/flashes/sweats
  - Loss of libido/impotence
  - Muscle weakness/wasting
  - Osteoporosis
  - Psychologic: Depression, memory difficulties, emotional lability
  - Testicular atrophy
  - Weight gain/increased body fat
  - There are no alternative therapies that will cure hypogonadism
  - No data to support the use of over the counter or direct to consumer “natural” T supplements.

### Ongoing Care
- Radiation therapy to restore T levels to the normal range by adjusting dosage of medication and improve symptoms of hypogonadism (4)

### Complications
- **Hypogonadism**: (5)
  - Metabolic syndrome: Anemia, increased fasting blood sugar, increased triglycerides, increased cholesterol, increased body fat
  - Appetite changes (increased or decreased)
  - Balance problems
  - Body hair loss
  - Dry eyes
  - Edema or leg pain
  - Fatigue
  - GI and/or respiratory disturbances
  - Dry mouth
  - Hot flashes/flashes/sweats
  - Loss of libido/impotence
  - Muscle weakness/wasting
  - Osteoporosis
  - Psychologic: Depression, memory difficulties, emotional lability
  - Testicular atrophy
  - Weight gain/increased body fat

### Prognosis
- Excise ability to restore T levels to the normal range by adjusting dosage of medication and improve symptoms of hypogonadism (4)

### Prognosis
- Excise ability to restore T levels to the normal range by adjusting dosage of medication and improve symptoms of hypogonadism (4)
TESTOSTERONE, DECREASED (HYPOGONADISM)

- T replacement:
  - Fluid retention
  - Gynecomastia
  - Hepatotoxicity
  - Sleep apnea
  - Theoretical risk of progression of prostate cancer: Unsubstantiated in recent studies

FOLLOW-UP

Patient Monitoring
- Every 3 mo (CBC, PSA, DRE) after starting treatment annually for response and adverse effects
- In men with known osteopenia or osteoporosis, bone mineral density should be verified after 6, 12, or 24 mo of TRT
- Monitoring lipid and glycemia is not routinely required for safety but should be done as part of general health maintenance

Patient Resources
- Urology Care Foundation AUA. www.urologyhealth.org/urology/index.cfm?article=132

- 799.81 Decreased libido

ICD10
- E29.1 Testicular hypofunction
- R68.82 Decreased libido
- R86.9 Unsp abnormal finding in specimens from male genital organs

CLINICAL/SURGICAL PEARLS
- Early morning serum total T below 300 ng/dL on at least 2 occasions in a symptomatic man usually confirms hypogonadism.
- Gonadotropins (LH and FSH) distinguish between a primary and a secondary cause.
- When caused by pituitary adenoma, patients can have additional symptoms due to mass effects, such as headaches or peripheral visual disturbance. There may also be signs and symptoms of other pituitary hormone deficiencies.
- Low T might be transient suppression (critical, acute/subacute illness, short-term use of certain medications; transient malnutrition; or excessive and chronic strenuous endurance exercise).
TORSION, TESTIS OR TESTICULAR/EPIDIDYMAL APPENDAGES
Julia S. Barthold, MD, FACS

BASICS

DESCRIPTION
- Torsion of the testicle or testicular appendages results in vascular compromise to the testicle or 1 of the appendages.
- Impaired perfusion of the testis, appendix testis, or appendix epididymis is caused by spermatic cord (intravaginal) torsion or appendix torsion.
- Presents as acute scrotal and/or inguinal pain with or without scrotal erythema and swelling.
- Occurs primarily in children.

EPIDEMIOLOGY
Incidence
- Most scrotal pain occurs at age 12–18
- Bimodal age distribution
- Puberty: Peak incidence of intravaginal testicular torsion, but can occur at any age

Prevalence
14,000 males <25 yo

RISK FACTORS
- Usually none
- Cryptorchidism
- History of contralateral torsion

GENETICS
- Rectal torsion reported in 10% of family members, may be autosomal or X-linked recessive
- No specific genetic defects identified

PATHOPHYSIOLOGY
- Testicular torsion can be either intravaginal or extravaginal
- Intravaginal testicular torsion
- Twisting of the spermatic cord within the tunica vaginalis
- Due to congenital incomplete fixation of testis within the tunica vaginalis (bell-clapper deformity, see images)
- Intermittent or sustained
- Impaired venous outflow, impaired arterial inflow, ischemia, potential testicular necrosis
- May progress to compartment syndrome
- Torsion: Usually painless and asymptomatic
- Appendiceal torsion
- Usually more gradual but may be acute
- Pain may be mild or severe
- Nausea/vomiting uncommon
- No prior episodes
- Impaired or abdominal pain may be associated or may be only site of pain in younger boys
- Inflamed epididymis reported as “epididymitis”

HISTORY
- Intravaginal testicular torsion
- Usually severe pain, sudden onset
- Nausea/vomiting more common
- May be recurrent usually same side
- Extravaginal testicular torsion
- Usually painless and asymptomatic
- Appendiceal torsion
- Usually more gradual but may be acute
- Pain may be mild or severe
- Nausea/vomiting uncommon
- No prior episodes
- Impaired or abdominal pain may be associated or may be only site of pain in younger boys
- Inflamed epididymis reported as “epididymitis”

PHYSICAL EXAM
- Note: Phren sign (elevation of scrotum relieves pain in epididymitis but in torsion it is no longer considered reliable)
- Intravaginal testicular torsion
- These are possible findings but these may be highly variable
- Early
  - Generalized testicular tenderness
  - Loss of spermatic cord Doppler
  - Elevated gonadotropin levels (see the appendix for this in intermittent testicular torsion cases)
- Appendiceal torsion
  - Late
  - Any of the above, increasing scrotal swelling and erythema
  - Loss of scrotal rugation ± hydrocele
  - Inability to distinguish epididymal landmarks
- Extravaginal testicular torsion
  - Firm to hard nontender testes
  - Scrotal discoloration
- Appendix torsion
  - Localized tenderness superior to testis
  - Supernumerary appendix
  - Preserved spermatic cord Doppler
  - Normal testicular position and orientation
- Blue dot sign: Rare, more likely in prepuberal/early pubertal boys; tender nodule with blue discoloration on the upper pole of the testis and more easily seen in light-skinned individuals
  - Lab
  - Any of the above
  - Generalized tenderness
  - Increasing scrotal swelling and erythema
  - Hydrocele

DIAGNOSIS

HISTORY
- Intravaginal testicular torsion
- Usually severe pain, sudden onset
- Nausea/vomiting more common
- May be recurrent usually same side
- Extravaginal testicular torsion
- Usually painless and asymptomatic
- Appendiceal torsion
- Usually more gradual but may be acute
- Pain may be mild or severe
- Nausea/vomiting uncommon
- No prior episodes
- Impaired or abdominal pain may be associated or may be only site of pain in younger boys
- Inflamed epididymis reported as “epididymitis”

PHYSICAL EXAM
- Note: Phren sign (elevation of scrotum relieves pain in epididymitis but in torsion it is no longer considered reliable)
- Intravaginal testicular torsion
- These are possible findings but these may be highly variable
- Early
  - Generalized testicular tenderness
  - Loss of spermatic cord Doppler
  - Elevated gonadotropin levels (see the appendix for this in intermittent testicular torsion cases)
- Appendiceal torsion
  - Late
  - Any of the above, increasing scrotal swelling and erythema
  - Loss of scrotal rugation ± hydrocele
  - Inability to distinguish epididymal landmarks
- Extravaginal testicular torsion
  - Firm to hard nontender testes
  - Scrotal discoloration
- Appendix torsion
  - Localized tenderness superior to testis
  - Supernumerary appendix
  - Preserved spermatic cord Doppler
  - Normal testicular position and orientation
- Blue dot sign: Rare, more likely in prepuberal/early pubertal boys; tender nodule with blue discoloration on the upper pole of the testis and more easily seen in light-skinned individuals
  - Lab
  - Any of the above
  - Generalized tenderness
  - Increasing scrotal swelling and erythema
  - Hydrocele

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis
  - If pyuria suspect epididymitis/UTI
  - If hematuria consider renal or ureteral source of pain (e.g., stone)
- Urine culture if indicated
  - Additional labs not needed

Imaging
- Social US with Doppler
  - Need to identify waveforms that originate in the central parenchyma
  - Intravaginal testicular torsion findings:
    - Usually shows decreased or absent arterial flow but may be normal
    - Increased flow possible in intermittent testicular torsion
    - Increased or mixed echogenicity suggests torsion: Compare both sides
    - Hydrocele and/or enlarged epididymis may be present
    - Visible twist of cord: Requires expertise but highly specific if present
    - Additional US findings:
      - Heterogeneous appearance typical
      - Doppler flow may be hard to demonstrate in neonatal testes
      - Calcification may be present
- Appendix torsion findings:
  - Normal exam must precede
  - Supernumerary complex mass w/o vascular flow may be present
  - Enlarged epididymis reported as “epididymitis” often present
  - Doppler flow normal or increased
  - Doppler flow normal
  - Thickened scrotal skin and hydrocele are nonspecific findings in acute scrotum cases
  - Nuclear scan: Rarely performed
Diagnostic Procedures/Surgery

Exploration for diagnosis if equivocal findings on exam and/or US; suspicion of testicular rupture, or tumor

Pathologic Findings

- Testicular necrosis (intravaginal) or subclinical loss of tubules with eddy current (extravaginal) testicular torsion
- Severity of injury depends on age, duration of testicular torsion, number of twists/thickness of spermatic cord
- In cases of appendicular torsion the necrotic tissue is reabsorbed usually without any sequelae

Differential Diagnosis

- Acute testicular pain
  - Appendicitis most common in prepubertal boys
  - Testicular torsion most common in peri-pubescent boys but can occur at any age; less common than epididymitis
  - Appendicitis due to LUTI or STD: Rare in pediatric age group
- Communicating hydrocele
- Incarcerated inguinal hernia
- Trauma and possible testicular rupture
- Noma testicularis present
- Orchitis (eg, mumps)
- Henoch–Schönlein purpura
- Rapidly usually present
- Fournier gangrene (rare in children)
- Delayed pain from orchidopexy or intra-abdominal process such as appendicitis
- Orchialgia; consider voiding dysfunction

Treatment

General Measures

- Testicular torsion: Consider manual detorsion in ER
  - Not effective; 1/3 of cases may rotate further
- Does not preclude need for immediate surgery
- Emergency surgery is indicated for all cases of testicular torsion

Medication

First Line

- Ibuprofen to reduce inflammation in appendix
  - Appendix torsion: Rest until pain resolves

Second Line

- None

Surgery/Other Procedures

- Emergent exploration indicated if evaluation suggests intraabdominal testicular torsion or diagnosis is equivocal
- Detorsion, observation for reperfusion, and bilateral orchidopexy via scrotal approach with fixation of tests extravaginally
- Consider capsulotomy if flow improves with placement of tunica vaginalis patch

- Urgent exploration, bilateral fixation for extravaginal testicular torsion to avoid asynchronous contralateral torsion
- Avoid imaging delays if findings are classic
- Elective surgery for resolved intermittent testicular torsion
- Consider delay in intraabdominal extraperitoneal testicular torsion if or testis appears nonviable after detorsion or circumscription
- Consider delayed prosthesis placement for mumps orchitis
- Appendix torsion
  - Prolonged pain not responsive to conservative measures
  - Recurrent episode (rare) or diagnostic uncertainty

Additional Treatment

- Radiation Therapy

Additional Therapies

- Experimental agents such as nitric oxide (NOS) inhibitors to reduce reperfusion injury in testicular torsion not used clinically

Complementary & Alternative Therapies

- N/A

Ongoing Care

Prognosis

- Intravaginal testicular torsion
  - Risk of postoperative atrophy increases with duration of torsion
  - Risk of contralateral torsion in the neonatal period
  - Risk of postoperative atrophy increases with duration of torsion
  - Risk of postoperative atrophy increases with duration of torsion
  - Risk of postoperative atrophy increases with duration of torsion
  - Risk of postoperative atrophy increases with duration of torsion

Complications

- Recurrent testicular torsion: Rare, occurs with failure of absorbable or nonabsorbable suture fixation of a testis that remains within an intact tunica vaginalis
- Testicular atrophy

Follow-Up

- Patient Monitoring
  - Follow for at least 6 mo to determine risk of atrophy
  - Monitor for recurrent testicular pain
  - Social protection in contact sports

- Education of healthy adolescent populations about the signs/symptoms of testicular torsion and the benefits of early evaluation and treatment
- Specific educational focus on family members of affected individuals

Patient Resources

- Torsion, Testis or Testicular/Epididymal Appendages

Icd9

- 608.20 Torsion of testis, unspecified
- 608.23 Torsion of appendix testis
- 608.24 Torsion of appendix epididymis

Icd10

- N44.00 Torsion of testis, unspecified
- N44.03 Torsion of appendix testis
- N44.04 Torsion of appendix epididymis

Clinical/Surgical Pearls

- Diagnosis of spermatic cord torsion requires a high index of suspicion, particularly in patients with intermittent testicular pain
- Emergent surgery is indicated for all cases of suspected spermatic cord torsion
- The risk of testicular loss increases after 4–6 hr of untreated spermatic cord torsion

519
ASSOCIATED CONDITIONS

Common causes include end-stage renal disease, diabetes, hypertension, glomerulonephritis, cystic renal disease.

GENERAL PREVENTION

- Avoid incompatible donors for kidney transplant recipients. Avoid transplants across a positive crossmatch or with preformed DSAs.
- Induction immunosuppression with lymphocyte-depleting agents, especially for high immunologic-risk recipients.
- Compliance with immunosuppressant medications.
- Monitor renal function and maintain therapeutic immunosuppressant drug levels.
- Minimize sensitizing events (eg, blood transfusions and pregnancies).

DIAGNOSIS

HISTORY

- Medication noncompliance or tapering off immunosuppression for a failed allograft.
- Often asymptomatic with plasma creatinine elevation as sole abnormality.
- Severe rejection may result in decreased urine output and pain over kidney transplant.
- Fluid retention/weight gain

PHYSICAL EXAM

- May be normal
- Increased blood pressure
- Volume overload
- May have tenderness over kidney transplant

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Rising BUN/plasma creatinine
- Rule out pyelonephritis.
- Otherwise unexplained plasma creatinine rise >20% over baseline is suggestive of rejection.
- Urinalysis and urine culture
- Rule out pyelonephritis.
- Determine drug levels (bacteriuria or cyclosporine)
- 12-24 hr trough level (usually before morning dose)
- Suspect calcineurin inhibitor (CNI: tacrolimus or cyclosporine) toxicity if abnormally high levels
- Target levels vary by patient and assay
- If antibody-mediated rejection (AMR) is suspected, test for donor-specific antibodies (DSAs)

Imaging

- Renal ultrasound
  - Rule out obstructive uropathy or stone.
  - Assess for diminished renal blood flow.
- Color flow Doppler evaluates vascular status
- Detect graft swelling (with acute rejection; graft may be small with chronic rejection).
- Nuclear medicine renal scan:
  - Rejection: Decreased renal blood flow/glomerular filtration rate
  - Arterial or venous thrombosis: Decreased or absent perfusion.
- Complete obstruction, a reniform photopenic area can be seen
- Acute rejection/tube/tubular necrosis: Marked parenchymal retraction with normal or mildly reduced perfusion. Rejection cell show progressive decrease in function over time.

Diagnostic Procedures/Surgery

- Needle biopsy of transplant kidney (continuation of rejection)
  - Usually under ultrasound guidance.
  - Automated biopsy gun device, needle sizes 14–18 gauge
  - Adequate sample
  - <2 cores of cortex, ≥2 glomeruli, and ≥2 arteries required

Pathologic Findings

- Acute cellular rejection
  - Interstitial mononuclear cell infiltrate
  - Tubules
  - Vascularis (in more-severe cases)
- Acute antibody-mediated rejection
  - Pathology variable
  - Acute tubular necrosis (ATN)
  - Glomerulitis
  - Peritubular capillaritis
  - Pyelonephritis
  - C3 glomerular (C6) is a complement split product that covalently binds to tissue indicating antibody-mediated complement activation
- Chronic rejection
  - Interstitial fibrosis
  - Tubular atrophy

DIFFERENTIAL DIAGNOSIS

- Prerenal: volume depletion or hypertension
- CNI (calcineurin inhibitor) toxicity (bacteriuria or cyclosporine)
- Pyelonephritis
- ATN
- Technical complications
  - Arterial or venous thrombus
  - Arterial stenosis
  - Urinary obstruction or urine leak (early posttransplant)
- Obstructive urology
- Recurrence of original renal disease
TREATMENT

GENERAL MEASURES
• Attempt to reverse rejection with medical therapy
• Graft removal may be necessary in severe rejection eg, hyperacute rejection.

MEDICATION
First Line
• Acute cellular rejection: High-dose glucocorticoids
  – Methylprednisolone 1–2 g IV bolus, 5 mg/kg/d for 3–5 days followed by taper to maintenance dosing
• Antibody-mediated rejection: Plasmapheresis and rituximab in attempt to remove, neutralize, or prevent the production of DSAs, respectively
• Chronic rejection: No effective therapy.
• Hyperacute rejection: Remove transplanted kidney (ZEA)
  – Can result in DIC if not removed promptly

Second Line
• Acute cellular rejection: Lymphocyte-depleting agents such as antithymocyte globulin (ATG) or alemtuzumab may be given for severe rejection or rejection refractory to high-dose glucocorticoid therapy (3A).
• Significant reactions possible with 1st doses (eg, hyperacute rejection).
• Monitor for recurrence of native kidney disease
• Continue maintenance immunosuppression

SURGERY/OTHER PROCEDURES
• Allograft nephrectomy
  – Remove a symptomatic, irreversibly rejected allograft
  – Remove an asymptomatic, chronically rejected kidney to withdraw immunosuppression and prevent further development of anti-HLA antibodies

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
• Severe rejection and graft failure may require acute dialysis

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
• Repeated episodes of acute rejection reduce allograft survival
• Relative risk of graft failure is 1.8 for patients who have had 1 episode of rejection compared to none (4)

COMPLICATIONS
• DIC can accompany hyperacute rejection
• Graft loss can result from untreated or unrecognized rejection episode
• Cyclosporin toxicity can resemble mild acute rejection
• Need to resume dialysis

FOLLOW-UP

Patient Monitoring (3)
• Compliance with anti rejection critical
• Therapeutic drug levels: Including monitoring of CNI toxicity
• Plasma creatinine
  – Monitor for recurrence of native kidney disease (eg, diabetes, hypertension, etc.)
• Protocol transplant biopsies (optional)

Patient Resources

CODES

ICD9
596.81 Complications of transplanted kidney
T86.12 Kidney transplant failure
T86.11 Kidney transplant rejection

ICD10
T86.1 Kidney transplant rejection
T86.12 Kidney transplant failure

CLINICAL/SURGICAL PEARLS
• Don’t confuse kidney transplant rejection with pyelonephritis
• Cyclosporin toxicity can resemble mild acute rejection.

521
**TRASURETHRAL RESECTION (TUR) SYNDROME**

**Raju Thomas, MD, MHA, FACS**

**Philip J. Dorsey, Jr., MD, MPH**

**DESCRIPTION**

- Transurethral resection (TUR) syndrome is classically associated with TUR of the prostate (TURP) and is characterized by confusion, hypotension (HTN), bradycardia, and visual disturbances.
- Symptoms are caused by hyponatremia, dilutional hyponatremia, and solute effects from irrigation absorption during resection.
- While traditionally associated with prostate resection, it can also be seen in TUR of bladder tumor (TURBT) and has also been described for procedures such as cystoscopy.
- Use of bipolar TURP and laser TURP techniques with normal saline irrigant has led to decreased incidence of TUR syndromes.
- Syncytial TURP syndrome

**EPIDEMIOLOGY**

**Prevalence**
- N/A

**Risk Factors**
- Resection time > 60 min
- Gland size > 45 g
- Intravesical pressures > 30 mm Hg
- Operative technique (open venous sinuses, capsular perforations increase risk)
- Sympathetic blockade associated with spinal anesthesia may contribute to late hypotension.

**Genetics**
- N/A

**PATHOPHYSIOLOGY**

- Irrigants used are osmotically active.
- Osmolarity of TUR irrigation solutions:
  - Normal saline: 280–310 mOsm/L
  - 5% mannitol: 275 mOsm/L
  - 2.5% sodium/0.5% mannitol: 178 mOsm/L
  - 3% dextrose: 165 mOsm/L
- Irrigant is absorbed by venous sinuses opened during resection or by slow absorption from the periurethral and perivesical spaces in case of capsular perforation.
- As osmotically active solute enters the intravascular space, the plasma sodium concentration drops, leading to hypo-osmolality.

**Volume effects:**
- Increase in intravascular volume initially leads to hypervolemia, HTN, and renal failure. As gland size increases, the left ventricle may also lead to PE and respiratory failure.

**ALERT**

After 35–50 min of resection, flow from the intravesical space to peripheral tissues increases and can cause hyponatremia and hypotension (2).

- Hypotension:
  - Caused by loading the intravesical space with nonelectrolyte solution.
  - Contributes to CNS disturbances.
- If severe enough, negative intraperitoneal pressures may initiate hypotension.

**DIAGNOSTIC TESTS & INTERPRETATION**

**PHYSICAL EXAM**

- Nonspecific physical findings: Although skin may be clammy, patient may complain of any of the following:
  - Headache
  - Lethargy
  - Confusion
  - Chest pain
  - Nausea and vomiting
  - Syncope of breath

**ASSOCIATED CONDITIONS**

- BPH
- Bladder tumors

**GENERAL PREVENTION**

- Using irrigants such as glycine, sorbitol, and mannitol solutions reduces the hemolytic effects associated with sterile water irrigation.
- Glycine is no longer recommended as an irrigation fluid.
- Intravesical pressure can be reduced by using continuous flow equipment, shunting the bladder with a suprapubic tube, or lowering the fluid height to ~60 cm.
- If a significant extraperitoneal perforation occurs during the TURP, or TURBT, it is best to abandon the procedure after achieving hemostasis to prevent excessive fluid absorption.
- Appropriate selection of patients for TURP is based on gland size:
  - Limited resection time to <60–90 min.
  - Consider open prostatectomy, or other appropriate options, for adenoma >100 g measured by imaging studies.
  - Judicious use of IV diuretics.
- Use of bipolar resectoscopes to perform TURP allows for saline irrigation.
- Reduces the hypo-osmotic effect of the absorbed fluid.
- Use of laser energy sources for TUR management also decreases occurrence of TUR syndrome.

**DIAGNOSIS**

A patient who is slow to awaken from anesthesia or complains of visual disturbances should be considered to have the TUR syndrome following TURP.

**HISTORY**

- During TURP procedure: HTN and bradycardia may be a prodrome to rapid reduction in BP.
- Postoperatively: No classic presentation, but patient may complain of any of the following:
  - Chest pain
  - Confusion
  - Headache
  - Lethargy
  - Nausea and vomiting
  - Syncope of breath

**PHYSICAL EXAM**

- Nonspecific physical findings: Although skin may be clammy

**LAB**

- Serum sodium < 125 mEq/L
- Serum ammonium and glycine may be elevated if glycine solution is used.
Hemodynamic and cardiopulmonary support should be provided as needed. Patients with normal renal function need no further intervention, except to be monitored for rapid correction of hyponatremia. Monitoring of serum sodium is essential. Prompt diagnosis, evaluation, and management are essential to prevent adverse events.

If a significant extraperitoneal perforation occurs, if therapy is delayed and hyponatremia is severe, risk of significant morbidity and mortality.

COMPLICATIONS
- Cardiopulmonary collapse
- Cerebral edema and brainstem herniation
- Seizures
- Transient blindness

FOLLOW-UP
- Patient Monitoring: Hemodynamic monitoring and close attention to serum electrolytes, especially sodium, is essential during and after procedure.
- Serial neurologic exams/mental status exams should be performed until symptoms improve.

Patient Resources

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Blender Suture Distraction (BSD)
- Hyponatremia, Urologic Considerations
- Prostate, Benign Hyperplasia/Hyper trophy (BPH)

CODES
- ICD9: 276.1 Hyponatremia and/or hyponatremia
- 276.99 Other fluid overload
- 195.9 Urological complications, not elsewhere classified
- ICD10: E87.3 Hypo-osmolality and hyponatremia
- E87.7 Fluid overload, unspecified
- N99.89 Oth postprocedural complications and disorders of fluid volume

CLINICAL/SURGICAL PEARLS
- Diagnosis of the TUR syndrome requires high clinical suspicion.
- Prompt diagnosis, evaluation, and management are essential to prevent adverse events.
- If a significant extraperitoneal perforation occurs during the TUR, consider abandoning procedure after achieving hemostasis to prevent excessive fluid absorption.
- Limit resection time to 60–90 min.
- Consider open prostatectomy, or other appropriate options (e.g., laser-assisted techniques), for adenoma >100 g.
- Use of bipolar resectoscopes to perform TUR permits use of saline irrigation reducing risk of TUR syndrome.
TROCAR INJURY DURING LAPAROSCOPY

Costas D. Lallas, MD, FACS
Leonard G. Gomella, MD, FACS

ASSOCIATED CONDITIONS
- For urologic laparoscopy: the underlying indication for the laparoscopy: (H)Nephrectomy (kidney, prostate, testicular, uterine, bladder)
- Observation: Ureteropelvic junction obstruction
- Invasion: Adenocarcinoma, retroperitoneal
- Others: Lymphoma, hemia

GENERAL PREVENTION
- Reason technique: (brusk down OR "open trocar placement") for initial access; allows direct visualization of peritoneum.
- Use of visual obturator trocar for primary port placement.
- Use of a nonbladed port for all ports.
- Utilization of confirmatory testing to ensure proper placement of initial Veress needle before full insufflation (4):
  - Modified Palmer test: Inject 10 mL of saline into the needle and attempt to aspirate. Inability to aspirate the fluid suggests that the fluid has dispersed into the abdomen and the needle is in correct position.
  - Initial pressure reading <8 mm Hg. The insufflator is turned on with no flow to obtain a pressure reading.
  - A decrease in pressure with elevation of the abdominal wall.
  - If perforation of a viscus occurs, the needle should be removed and discarded. A new needle may then be inserted at another location or the surgeon may choose to obtain open access using the Hasson technique. The injury should be observed laparoscopically or through open intervention if there is any concern over the degree of injury.
- Utilizing a LUS insertion site (Palmers point, located 3 cm above the middle of the left costal margin, for primary port)
- Increase pneumoperitoneum to 20–25 mm Hg during port placement to increase tension of abdominal wall and decrease posterior displacement during trocar insertion
- Ensure adequate skin incision for trocar size to avoid excess insertion pressure
- Subdiaphragm abdominal wall when inserting trocar
- Describe vision of secondary port placement and transfundulation of abdominal wall to avoid more superficial vessels
- Bladder catheter placement
- Nasogastric tube placement
- Surgeons should completely familiarize themselves with a new trocar device or design before 1st use
- Visualization of port removal can help identify unrecognized anterior abdominal wall vascular injury.

DIAGNOSTIC TESTS & INTERPRETATION
- Lab: Sudden unexplained drop in blood pressure at the beginning of the case consistent with unrecognized major vascular injury
- Need to differentiate from insufflation causing compromised blood pressure

DIAGNOSTIC PROCEDURES/SURGERY
- Primary site of injury
- Pathologic Findings
- Differential Diagnosis

PHYSICAL EXAM
- Intraoperative findings that suggest trocar injury:
  - Blood in the port after initial placement
  - Retroperitoneal hemorrhage on initial abdominal inspection
  - Air in the bladder catheter bag after initial trocar placement
- Visualization of port removal can help identify unrecognized anterior abdominal wall vascular injury
- Drop pneumoperitoneum to 5 mm Hg at the end of the case to uncover possible significant small vessel or venous bleeding.

DIFFERENTIAL DIAGNOSIS
- Sudden loss in vision without mydriasis
**TREATMENT**

**GENERAL MEASURES**
- In general Veress needle injuries often heal with conservative management whereas trocar injuries or gross spillage of bowel contents require formal repair
- Direct injury may be observed laparoscopically or during conversion laparotomy
- Abdominal wall/gastric vessel bleeding may be recognized after ports are removed under direct visualization
- If a port is placed into a major vessel, do not remove but keep in place during laparotomy
- During an emergent open conversion, use anteriorly deflected port or laparoscope to cut down into abdomen (unless in major vessel)

**MEDICATION**

**First Line**
N/A

**Second Line**
N/A

**SURGERY/OTHER PROCEDURES**

- **Laparoscopic or open repair of injury**
  - Always have open tray available for each case
  - If the Veress needle aspiration returns frank blood or other fluid (T)
    - Consider leaving the needle in place to help tamponade and identify the injury site
    - If the patient is unstable, consider an alternate access site and laparoscopically evaluate the site.
  - For abdominal wall bleeding:
    - Clips or electrocautery
    - Advancement of a central venous line into the right heart with subsequent attempts to aspirate gas may sometimes be helpful.
  - For gas embolism (4):
    - Immediate cessation of insufflation and prompt deflation of the peritoneal cavity
    - Advancement of a central venous line into the right heart with subsequent attempts to aspirate gas may sometimes be helpful.
  - **Bladder injury**:
    - Veress needle injury can usually be managed by bladder catheter for 7–10 days
    - More significant injury requires 2-layer closure with absorbable suture and catheter drainage
  - **Bowel injury**:
    - Requires further inspection and repair either laparoscopically or via laparotomy.

**ADDITIONAL TREATMENT**

**Radiation Therapy**
N/A

**Additional Therapies**

**Complementary & Alternative Therapies**
N/A

**ONGOING CARE**

**PROGNOSIS**
- Excellent if injury is recognized and managed quickly.
- Delayed or unrecognized visceral injury can lead to significant morbidity or mortality.
- Many bowel injuries are not recognized initially and typically present with peritonitis.

**COMPLICATIONS**
- Unrecognized injury can lead to ongoing hemorrhage, infection.

**FOLLOW-UP**
- Dependent on injury and management.

**Patient Resources**

**REFERENCES**

**CODES**

**ICD9**
- 902.9 Injury to unspecified blood vessel of abdomen and pelvis
- 998.3 Accidental puncture or laceration during a procedure, not elsewhere classified

**ICD10**
- S35.91XA Laceration of unspecified blood vessel during laparoscopy
- S35.91XA Laceration of unspecified blood vessel of abdomen, lower back and pelvis level, initial encounter
- S36.90XA Unspecified injury of unspecified abdominal organs, with open wound into cavity
- K91.72 Acc pnctr & lac of a dgstv sys org during oth procedure
- S33.91XA Laceration of unspecified blood vessel at abdomen, lower back and pelvis level, initial encounter
- 998.3 Accidental puncture or laceration during a procedure, not elsewhere classified

**CLINICAL/SURGICAL PEARLS**
- **Bladder injury**:
  - Veress needle injury can usually be managed by bladder catheter for 7–10 days
  - More significant injury requires 2-layer closure with absorbable suture and catheter drainage
  - Bowel injury:
    - Requires further inspection and repair either laparoscopically or via laparotomy.

**RISK FACTORS**

- Immunocompromised states (e.g., AIDS)
- Malnutrition
- Poor living conditions/poverty/drug use
- Malnutrition
- Chronic TB infection
- Chronic cystitis unresponsive to therapy
- Dysuria from seeding of the bladder with TB
- Men commonly present with epididymitis.
- Vague, intermittent, nonspecific complaints such as malaise, lethargy, weight loss, and low-grade fevers common.
- Common presentation with epididymitis.
- Kidney and epididymis are primary sites of TB infection in the GU tract in men, and tubular tubules in women.
- Tuberculosis develops in glomerular capillaries as a result of hematogenous seeding from lungs.
- Normal renal parenchyma is slowly replaced by caseous material; calcium is laid down as part of the reparative process.
- Adrenal TB is seen in <6% of active TB cases (up to 56% of patients with adrenal TB will have a subnormal cortisol response to corticotrophin stimulation).

**BASICS**

- **DESCRIPTION**
  - Genitourinary tuberculosis (TB) refers to urinary and GU infection with Mycobacterium tuberculosis. Common GU sites include the kidney, urinary bladder, prostate, and testicles/epididymis.
  - GU tract is 2nd most common site after lungs for tuberculosis infection. Unreported TB represents 27% of extrapulmonary cases (1).
  - Tuberculosis found in 7–29% of urine in patients with extrapulmonary TB.
  - In 1882, the bacillus causing TB, M. tuberculosis, was first identified and described by Robert Koch.
  - 10% of TB is extrapulmonary with GU locations accounting for 33% of these sites and these rates double in developing countries.
  - TB is 2nd only to HIV/AIDS as the greatest killer of women aged 15–44.
  - 10% of TB is extrapulmonary with GU locations accounting for 33% of these sites and these rates double in developing countries.
  - TB is 2nd only to HIV/AIDS as the greatest killer of women aged 15–44.
  - 10% of TB is extrapulmonary with GU locations accounting for 33% of these sites and these rates double in developing countries.

- **ASSOCIATED CONDITIONS**
  - Chronic TB infection
  - Immunocompromised states (e.g., AIDS)
  - Malnutrition
  - Poor living conditions/poverty/drug use
  - Malnutrition
  - Chronic cystitis unresponsive to therapy
  - Dysuria from seeding of the bladder with TB
  - Men commonly present with epididymitis.
  - Vague, intermittent, nonspecific complaints such as malaise, lethargy, weight loss, and low-grade fevers common.
  - Common presentation with epididymitis.
  - Kidney and epididymis are primary sites of TB infection in the GU tract in men, and tubular tubules in women.
  - Tuberculosis develops in glomerular capillaries as a result of hematogenous seeding from lungs.
  - Normal renal parenchyma is slowly replaced by caseous material; calcium is laid down as part of the reparative process.
  - Adrenal TB is seen in <6% of active TB cases (up to 56% of patients with adrenal TB will have a subnormal cortisol response to corticotrophin stimulation).

**HISTORY**

- Initial symptoms may be minimal, even in presence of extensive disease. No classical clinical picture, most symptoms are of bladder/urinary origin.
- History or exposure to TB; determine past PPD testing results; latency can be >20 after primary TB.
- Vague, intermittent, nonspecific complaints such as malaise, lethargy, weight loss, and low-grade fevers common.
- Common presentation with epididymitis.
- Kidney and epididymis are primary sites of TB infection in the GU tract in men, and tubular tubules in women.
- Tuberculosis develops in glomerular capillaries as a result of hematogenous seeding from lungs.
- Normal renal parenchyma is slowly replaced by caseous material; calcium is laid down as part of the reparative process.
- Adrenal TB is seen in <6% of active TB cases (up to 56% of patients with adrenal TB will have a subnormal cortisol response to corticotrophin stimulation).

**PATHOPHYSIOLOGY**

- Hematogenous spread to kidneys from pulmonary disease proved by Medlar, et al. in 1949.
- 2–12 wk; often ensue before mycobacterial numbers are sufficient to mount a clinically detectable cellular immune response.
- M. tuberculosis infections acquired by inhalation of aerosolized droplet nuclei (1–5 μm), which reach pulmonary alveoli.
- Invasion of GU organs by ascept (prostate to bladder) or decendent (kidney to bladder, prostate to epididymis).
- Kidney and epididymis are primary sites of TB infection in the GU tract in men, and tubular tubules in women.
- Tuberculosis develops in glomerular capillaries as a result of hematogenous seeding from lungs.
- Normal renal parenchyma is slowly replaced by caseous material; calcium is laid down as part of the reparative process.
- Adrenal TB is seen in <6% of active TB cases (up to 56% of patients with adrenal TB will have a subnormal cortisol response to corticotrophin stimulation).

**DIAGNOSIS**

- **PHYSICAL EXAM**
  - Physical exam is often of limited value in the diagnostic process, because physical signs develop late in the disease. The most common physical finding is an abdominal scirrhold mass in about half the patients.
  - Suspected when disease is extensive
  - Painful scissel tests
  - Chronic draining scrotal sinuses should be considered TB until proven otherwise.
  - Nodular, indurated prostate and thickened seminal vesicles on rectal exam mitotic neoplasms.
  - Upper abdominal bruit may be indication of advanced renal disease.
  - Up to 25% of patients will present only with sterile pyuria and 13% might have gross or microscopic hematuria as their only presentation.

- **TUBERCULOsis, Genitourinary, General Considerations**

  - **DESCRIPTION**
    - Genitourinary tuberculosis (TB) refers to urinary and GU infection with Mycobacterium tuberculosis. Common GU sites include the kidney, urinary bladder, prostate, and testicles/epididymis.
    - GU tract is 2nd most common site after lungs for tuberculosis infection. Unreported TB represents 27% of extrapulmonary cases (1).
    - Tuberculosis found in 7–29% of urine in patients with extrapulmonary TB.

      - Upper abdominal bruit may be indication of advanced renal disease.
      - Up to 25% of patients will present only with sterile pyuria and 13% might have gross or microscopic hematuria as their only presentation.
Medication

**DIFFERENTIAL DIAGNOSIS**

- **Aminic cystitis**
- **BCG urologic/Cystitis**
- **Chronic nonspecific cystitis or pyelonephritis**
- **Disseminated coagulopathies**
- **Granulomatous prostatitis, prostatic cancer**
- **Mediastinal sponge kidney**
- **Necrotizing papillitis**
- **Nonspecific-epididymitis**
- **Renal stones or nephrocalcinosis**
- **Urinary lithiasis (chrocomiasis)**

**TREATMENT**

**GENERAL MEASURES**

- **Quarantine until appropriate medications**
- **Screen close contacts**

**MEDICATION**

**First Line (2)**

- **Antituberculous drugs**: isoniazid, rifampin, pyrazinamide, ethambutol, and streptomycin.
- **Patient with uncomplicated TB infection**: isoniazid (300 mg/d), rifampin (550–600 mg/d), and pyrazinamide (25 mg/kg) once a day in the morning, 3 times a week, for 2–4 mo, followed by isoniazid and rifampin once a day, 3 times a week, for an additional 2–4 mo. (Add 1 g of vitamin C, 3 times a week, for 4 mo with above regimen).

**Second Line**

- **Patient with complicated TB infection**: Add streptomycin to the above for severe infection or severe bladder symptoms.
- **Drug resistance**: increasing and necessitates tight therapy control. Expand antibiotic regimen of 4 of the following: ethambutol, pyrazinamide, quinolones, thiamphenicol, ciprofloxacin, kanamycin, ciprofloxacin, capreomycin, thiocarbazone, and para-amoxycycline.
- **Steroids**: No role in initial therapy but can be used for acute TB cystitis or structure at distal ureter (maintenance 20 mg PO TID).

**SURGERY/OTHER PROCEDURES**

- **Nephrectomy**: for symptomatic or severe renal or clinical renal cell carcinoma.
- **Peritoneal nephrectomy**: for severe renal or clinical renal cell carcinoma.
- **Pericystectomy**: indicated for caseating abscess. Perform 4–6 wk after onset of antituberculous drugs.
- **Epididymectomy**: Indicated for chronic draining scrotal sinus. Perform 4–6 wk after start of antituberculous drugs.
- **Bladder augmentation**: Small capacity, fibrotic bladder. Surgery not necessary for TB abscesses; Treat medically.

**ONGOING CARE**

**PROGNOSIS**

- **Awareness of renal TB is urgently needed by physicians to suspect this disease in patients with unexplained urinary tract abnormalities, mainly in those with any immunosuppression and those coming from TB-endemic areas**.
- **No specific statistics, but overall patients can do well with appropriate, early antituberculosis medications and surgical interventions**.

**COMPLICATIONS**

- **Urinary TB**: formation of hematomas, hydronephrosis, scarring, and renal destruction
- **Complete nonfunctioning of an affected kidney (“autonephrectomy”)**
- **Renal TB**: Obliteration of the renal and psoas shadow on plain radiographs, perinephric abscess may cause an enlarging mass in the flank.
- **Genital TB**: Stenosis as a consequence
- **Bladder TB**: Stenosis of ureterovesical junction, fibrosis, and contracture of bladder
- **Nephrotoxicity induced by antimicrobial agents (especially rifampin)**

**FOLLOW-UP**

- **Completion of TB regimen long term is essential.**
- **Structures can evolve after organism is eradicated.**
- **Follow regularly after completion of therapy as stricturing can continue**.
- **Need long-term imaging follow-up of calcifications**.

TUBERCULOSIS, KIDNEY AND URETER

Mohamed S. Ismail, MBChB, MRCS, PhD
Jayram Krishnan, DO, MBA

ASSOCIATED CONDITIONS
- Chronic TB infection
- Immunocompromised states (HIV/AIDS)
- Malnutrition
- Poor living conditions/notify

GENERAL PREVENTION
- Diagnose and treat patients with TB before development of active disease
- Take careful precautions with patients hospitalized with TB
- Test annually with the purified protein derivative (PPD) skin test if at high risk for exposure

DIAGNOSIS

HISTORY
- Often mimics a wide range of nonspecific urologic symptoms and are often renal flare with extensive disease
- History or exposure to TB; determine last PPD test results; latency can be > 20 yr after primary TB
- Vague, intermittent, nonspecific complaints such as malaise, lethargy, weight loss, and low-grade fevers common
- Men commonly present with epididymitis
- Bacterial cystitis may be superimposed on bladder with TB

PHYSICAL EXAM
- Significant physical signs develop late with extensive disease
- Storage symptoms are the most common overall presentation (55.4%)(11)
- Hematuria (35.6%)(11)
- Lumbar pain (44.4%)(11)
- Most common physical finding in men is an abnormal urinalysis (49.8%)(11)
- Scolial lumps, epididymal hardening, or draining abnormal scrotal exam (49.8%)(11)
- Upper abdominal bruits may indicate advanced renal disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis and culture:
  - Clue finding: sterile pyuria (>20 white blood cells/high power field)
  - 20% of patients will also have bacterial cystitis or urinary tract infection with E. coli
  - 13% of patients will present with gross or microscopic hematuria (10)
- GOLD STANDARD: Specific staining of urine for acid-fast bacteria and mycobacterial culture
- Nontuberculous mycobacteria can also stain positive, so culture more useful
- Ziehl-Neelsen or Kinyoun acid-fast stain; more rapid if fluorescent microscopy
- 1st morning urine specimen has highest yield of tubercle bacilli

- Minimum 3 and up to 6 early-morning urine specimens are recommended, as TB organisms shed into urine intermittently.
- 64.2% of patients had M. tuberculosis in their urine (11)
- High index of suspicion for persistent pyuria without bacteria on repeated cultures (stain with methylene blue)
- Polynuclear chain reaction (PCR) assay may identify organisms
- Complete blood count and electrolytes
- Renal failure is present in 7.4% of cases (creatinine > 1.5)(11)
- Functional loss of the affected kidney can be present in up to 25% of cases (11)
- Erythrocyte sedimentation rate (ESR)
- Measure monthly as indicator of response to therapy
- Proteinuria may suggest secondary involvement of the kidney with amyloidosis

Imaging
- Chest radiograph: Abnormal in 75%
- Abdominal radiograph:
  - Enlargement of 1 kidney
  - Renal stones in 10%
  - Focal punctate calcifications occur within the caudate lesions in renal parenchyma
  - Obliteration of psoas shadow due to perinephric abscess
- Characteristic diffuse, uniform, extensive parenchymal calcifications are present with lobar cast of the kidney (auto nephrectomy)
- Scarring pattern:
  - Nodular or linear appearance in atrophied calyces (4E)
  - Obliteration of upper tract secondary to ureteral stricture (4F)
  - Obliteration of calyces
  - Loss of kidney function due to complete occlusion or renal destruction
- Computed tomographic (CT)
  - Most common finding: Renal parenchymal sarcoidosis (75%)
  - Hydronephrosis, hydropnephrosis, or hydronephrosis due to stricture (67%) (11)
  - Thick walls of the renal pelvis, ureters, and bladder (67%)

Diagnostic Procedures/Surgery
- Tuberculin skin test (PPD):
  - 98% patients have positive skin tests
  - 5 mm or more of induration is considered positive in persons with the highest likelihood of developing active disease
  - HIV, immunosuppression, organ transplants
  - 15 mm or more of induration is considered positive in those who are at high risk for TB
- Drug abuse, health care workers, family members
  - 15 mm or more of induration is considered positive in any patient
- Positive reaction indicates exposure, not necessarily active disease
**MEDICATION**

**GENERAL MEASURES**

- Early diagnosis of active disease is imperative and requires prompt initiation of adequate drug regimens.
- Surgical treatment is reserved for advanced cases and with the goal of renal preservation.
- Correct the obstructive effects of fibrosis and scarring rather than removal of infected tissues.
- Drainage of abscesses
- Balanced approach is required between medications and surgery to preserve function and eradicate mycobacteria.
- A surgical approach is required if medications and surgery do not achieve adequate disease response.
- Compliance to treatment regimen is essential for adequate disease response.

**COMPLICATIONS**

- Loss of renal function
- Hydronephrosis
- Hyponatremia
- Perinephric abscess may cause an enlarging flank mass
- Autonephrectomy: Complete nonfunctioning of an affected kidney
- Resistant to at least isoniazid and rifampin, and possibly additional agents
- Extensively drug-resistant TB (XDR-TB)
- Resistant to at least isoniazid and rifampin, and additionally resistant to fluoroquinolones and other antimicrobials or both

**SURGERY/OTHER PROCEDURES**

- 55% of patients with GU TB will require surgical intervention
- Ureteral obstruction
- Early stent or nephrostomy may decrease loss of renal function and increase opportunity for later reconstruction (2JE)
- Some strictures may resolve after medical therapy
- Nephrectomy
- Steroids
- Prednisone 20 mg 3 times daily orally
- Some strictures may resolve after medical therapy
- Enteric or nephrostomy tubes
- Nephrostomy
- Drainage of abscesses
- Percutaneous renal drainage
- Percutaneous or ureteral stent
- Ureteral stricture
- Early stent or nephrostomy may decrease loss of renal function
- Not recommended for routine use
- Some strictures may resolve after medical therapy
- Late strictures are refractory to medical therapy and require surgical intervention
- Stents
- Used for treatment of TB-induced ureteral strictures or cysts
- Prednisone 20 mg 3 times daily orally
- Not recommended for routine use
- Late strictures are refractory to medical therapy and require surgical intervention
- BCG Sepsis/BCGosis
- Prostatitis, Granulomatous
- Tuberculosis, Bladder and Urethra
- Tuberculosis, Genitourinary, General Considerations
- Tuberculosis, Kidney and Ureter
- Tuberculosis, Male External Genitalia

**Ongoing Care**

- Prognosis is good in patients who are compliant in therapy
- Better prognosis with early diagnosis of disease

**Follow-up**

- All TB patients should be screened for HIV/AIDS
- Structures can evolve after mycobacteria is eradicated
- Imaging (excretory urography/contrast computed tomography) and urine culture every 3 mos for 1st yr then annual abdominal radiographs
- Continue long-term imaging if calcifications present

**ADDITIONAL READING**

**ICD9**

- 016.20 Tuberculosis of ureter, unspecified
- 016.20 Tuberculosis of kidney, unspecified

**ICD10**

- A16.11 Tuberculosis of kidney and ureter

**CLINICAL/SURGICAL PEARLS**

Compliance to treatment regimen is essential for adequate disease response.
TUNICA ALBUGINEA/PARATESTICULAR TUMORS AND CYSTS
John L. Phillips, MD, FACS
Vladimir A. Valera, MD, PhD

PATHOPHYSIOLOGY

- Arise from epithelial, mesothelial, or mesenchymal tissues
  - Epithelium
  - Adenomatoid tumor
  - Cystadenoma (1/3 occur in VHL)
  - Spermatic cord
  - Sarcoma (arise from undifferentiated mesoderm)
  - Adenoma (found incidentally during hernia repair)
  - Lipoma/leiomyoma/liposarcoma, etc.
  - Tunica vaginalis (TV)
  - MM

ASSOCIATED CONDITIONS

- Germline conditions
  - Von Hippel–Lindau disease
  - Li–Fraumeni syndrome
  - Nevoid basal cell carcinoma syndrome
  - Li–Fraumeni syndrome

- Somatic (acquired) conditions
  - Inflammatory/infectious scrotal conditions
  - Morphologic changes (and asbestos exposure in MM of the TV)

- Solid masses require exploration
  - Cystic structures such as tunica albuginea cyst may be monitored serially
  - CT scan of the chest, abdomen, and pelvis required when malignancy suspected and to rule out metastasis in cases of known malignancy

DIAGNOSTIC PROCEDURES/SURGERY

- Fine needle aspiration may lead to false negatives or positives
- Solid lesions require inguinal approach
- Germ lesions
  - Observation
  - Testis-sparing surgery
- Malignant or suspicious lesions
  - Radical orchiectomy, inguinal approach
  - High dissection to internal ring
  - Early vascular control
- Removal of adenohypophysis
- Skin
  - Fascia
  - Muscle

Pathologic Findings

- Benign lesions usually need low power H&E
- Adenomatoid tumor
  - Well circumscribed
  - May involve tunica albuginea
- Benign appearing cords and cystic tubules lined by eosinophilic cells with small nuclei
- Focal cystadenoma
  - Well circumscribed
  - Brown fronds within cystic space
  - May have clear cells that resemble renal cell carcinoma commonly associated with VHL
- Malignant lesions may need electron microscopy
  - Stalk
  - Rhabdoid, multiphasic within hydrocele
  - Epithelioid, papillary, tubulovillous pattern
  - Fibrovascular core
  - Rhabdomyosarcoma (RMS)
  - Embryonal in 90%
  - Alveolar
  - Mixed pleomorphic

DIAGNOSIS

HISTORY

- Slowly growing inguinal or scrotal mass
- Often painless
- Found in workup for herna
- Found in evaluation of scrotal trauma or inflammation/infectious scrotal conditions

PHYSICAL EXAM

- Inguinal or scrotal mass
- Tenderness or discoloration and normal
- Adenomatous tumors may occur more inferiorty on the testis
- Superior pole tumors may mimic a spermaticcele (SC)
- Evaluate for herna, hydrocele, SC, and varicocele

ALERT

- Fixation to inguinal canal or testis suggests malignancy. Prepare for and rule out sarcoma.
- Fixation or involvement of testis and not the cord suggests primary testicular or MM
- Rule out germ cell tumor or MM
- Large size > 5 cm suggests RMS

ALERT

- Transformation does not rule out tumor
- Rule out secondary or, more so, primary lymphoma.
Therapies
Additional Therapies
malignant PT sarcomas
Reserved for local adjuvant or salvage control of
Radiation Therapy
ADDITIONAL TREATMENT
N/A

DIFFERENTIAL DIAGNOSIS
Epidermoid tumors (rare)
—Adenocarcinoma
—Cystadenoma
—Proliferative papillitis
—Resemble nodular fascitis
—Incidental at hemiorrhaphy
—Hematoma, direct or indirect
—Hydrocele
—Lymphadenopathy
—Secondary resection
—Vasitis nodosa
—Tunica albuginea cyst
—Vasitis nodosa

TREATMENT
GENERAL MEASURES
—Cephalic PT structures are treated with observation or rarely post-vasectomy.
—Secondary hernia
—Pain
—Hematoma
—Infection
—Secondary resection

MEDICATION
First Line
—Malignant rhabdomyosarcoma (RMS)
—Vincristine
—Dactinomycin
—Muscle biopsy
—METHA for bladder protection

Second Line
IFL

ADDITIONAL TREATMENT
Radiation Therapy
Reserved for local adjuvant or salvage control of malignant PT sarcomas

Additional Therapies
Secondary resection
—Local recurrence of benign lesions
—Local recurrence of malignant lesions if localized, no evidence of metastatic disease, and radiation not given

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
Benign lesions
—Resolution is usually curative
—Fertility can be maintained
—Malignant lesions
—RMS
—Favorable prognosis in children
—Stage I in 60–80%
—Unfavorable prognosis in adults and children
—>10 yr
—DRT unfavorable prognosis with nodal and pulmonary metastasis
—Malignant: Aggressive; similar to peritoneal mesothelioma
—Lipo-/leiomyosarcoma
—Excellent prognosis but may recur locally and require retreatment
—Metastases exceedingly rare, reportable

COMPLICATIONS
—General as seen for inguinal surgery
—Secondary hernia
—Infection
—Hematoma
—Pain
—Loss of tests after testicular sparing surgery (TSS) (rare)
—Infertility (eg, after excision of bilateral cystadenoma or epididymal masses in VHL)

FOLLOW-UP
Patient Monitoring
—Benign lesions
—Physical exam semiannual and self-exam yearly
—Malignant lesions
—Liposarcoma rarely metastasize but can recur locally
—RMS
—Immunosuppressive oncologic team (O)
—Serial imaging
—40% metastases to retroperitoneum
—Role of RPLND in RMS controversial

CLINICAL/SURGICAL PEARS
—Most common benign adult paratesticular tumor: Lipoma
—Most common adult malignant paratesticular tumor: Liposarcoma
—Most common pediatric PT tumor is malignant RMS (Rhabdomyosarcoma)
— Cure rate of RMS with multimodality therapy: 90%
UMBILICAL ABNORMALITIES, UROLOGIC CONSIDERATIONS

Evalynn Vasquez, MD, MBA
Derek Matoka, MD

BASICS

DESCRIPTION

- Umbilical abnormalities result from failure of umbilical cord to close or persistence of umbilical structures.
- Abnormalities can be classified as:
  - Uss: Umbilical sinus
  - Infection: Umbilical granuloma
  - Persistent drainage: Umbilical fistula
- Most likely to present during the neonatal period or early infancy

EPIDEMIOLOGY

Incidence
- Most common mass at the umbilicus in an infant is umbilical hernia with a prevalence of 1/1000 live births

Prevalence
- N/A

PATHOPHYSIOLOGY (1)

- The primitive umbilical cord develops with the anterior abdominal wall during weeks 2–3 of gestation.
  - Early in gestation, the umbilical cord contains the vitelline duct, allantois, two arteries, and one vein.
  - The vitelline duct is a connection between the midgut and yolk sac. It involutes to the ligamentum teres of the liver.
  - The ligament attaches to the inferior portion of the umbilicus. The urachus involutes to a fibrous cord leaving only an umbilical ring.
- Urachal remnants are common but often asymptomatic (1% of adult autopsy specimens).
- Failure of normal development or failure of development results in umbilical abnormalities:
  - Omphalitis: Tender, erythematous, bleeding, and infective process of the umbilicus.
  - Umbilical hernia: 10–20% of all infants
  - Umbilical sinus: Umbilical granuloma
  - Urachal remnants are common but often asymptomatic (1% of adult autopsy specimens)
- Patent urachus occurs in 1/8000 live births
- Urachal carcinoma: 1 in 5 million cases annually

ASSOCIATED CONDITIONS

- Vitelline umbilical fistula: Found in newborn period with the appearance of an umbilical stoma with pink, circular, intestinal remnant.
- Medial diverticulum: Asymptomatic unless bowel obstruction from intussusception occurs or GI bleed due to mucosal ulceration from acid secretion.
- Meckel diverticulum: May present with urinary tract infections.
- Vitelline umbilical fistula: Found in newborn period with the appearance of an umbilical stoma with pink, circular, intestinal remnant.
- Medial diverticulum: Asymptomatic unless bowel obstruction from intussusception occurs or GI bleed due to mucosal ulceration from acid secretion.
- Meckel diverticulum: May present with urinary tract infections.

HISTORY

- Most umbilical disorders are found antenatally or at birth and can be diagnosed prenatally.
- Urachal carcinoma may be positive in cases of umbilical carcinoma.

DIAGNOSIS

HISTORY

- Most umbilical disorders are found antenatally or at birth and can be diagnosed prenatally.
- Urachal carcinoma may be positive in cases of umbilical carcinoma.

PHYSICAL EXAM

- Ultrasound: Evaluates anterior abdominal wall.
- CT or MRI of abdomen and pelvis with IV and PO contrast: Assess the fluid level and determine if it could be a patent urachus.
- Meckel scan: Specific for gastric mucosal cells and evaluates for bladders/small bowel communication.
- VCUG: Assess for a urachal remnant and can rule out associated bladder outlet obstruction.

Lab

- Urinalysis: Evaluate hematuria or infection.
- Check creatinine of draining umbilical fluid to determine if it could be a patent urachus.
- Urine cytology may be positive in cases of urachal carcinoma.

Imaging

- Ultrasound: Best tool for initial assessment. It accurately determines anatomy of umbilical structures and evaluates for bladder/small bowel communication.
- VCUG: Assess for a urachal remnant and can rule out associated bladder outlet obstruction.
- Radiography/Sonography: Catheterization of tract and injection of contrast may be difficult and unreliable.
- CT or MRI of abdomen and pelvis with IV and PO contrast: Gold standard for diagnosis and staging particularly for cancer.
-eline, calcified, partially obstructed with local extension is concerning for but not diagnostic of urachal carcinoma.

Diagnostic Procedures/Surgery

- Cesarean: For delivery of babies with umbilical abnormalities.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Ultrasound: Best tool for initial assessment. It accurately determines anatomy of umbilical structures and evaluates for bladder/small bowel communication.
- VCUG: Assess for a urachal remnant and can rule out associated bladder outlet obstruction.
- Radiography/Sonography: Catheterization of tract and injection of contrast may be difficult and unreliable.

- CT or MRI of abdomen and pelvis with IV and PO contrast: Gold standard for diagnosis and staging particularly for cancer.
Pathologic findings

- Urachal polyp: Persistence of urachal remnant
- Urachal adenocarcinoma: Malignant tumor
- Urachal sinus: Fistula connecting the bladder to the umbilicus
- Urachal abscess
- Umbilical polyp: Granuloma
- Umbilical hernia: Defect in the abdominal wall
- Umbilical cancer: Malignant tumor

Identify the abnormality and manage accordingly.

GENERAL MEASURES

Pathologic Findings

- Patent urachus: Resect entire duct via infra-umbilical incision.
- Omphalitis (infants): Broad spectrum antibiotics.
- Granuloma and umbilical polyp (infants): Very difficult to differentiate clinically.

DIFFERENTIAL DIAGNOSIS

- Umbilical hernia: All ages
- Urachal neoplasm: Adults
- Bezold (very rare): Adenomas, fibromas, endometriosis, hydatid cysts
- Malignant (very rare, less than 0.5% of all bladder cancers): Most adenocarcinoma
- Sister Mary Joseph nodules (adults): Umbilical metastases of primary tumors (if primary is known, usually from genital or GI tract)
- Others: Dermoid cyst, sebum cyst, spontaneous umbilical fistula from Crohn disease/Meckel's diverticulum, umbilicus, posterior rectus sheath, and skin cancers such as basal-cell and squamous-cell carcinoma
- Infection
- Omphalitis
- Infected urachal cyst
- Drainage
- Urachal remnant
- Patent urachus (50%)
- Blind urachus (30%)
- Urachal sinus (15%)
- Vesicourethral fistula (9%)
- Vesicovaginal fistula (9%)
- Vesicovaginal fistula (9%)

TREATMENT

GENERAL MEASURES

- Identify the abnormality and manage accordingly.

SURGERY/OFFICE PROCEDURES (2,3)

- Granuloma and umbilical polyp (infants): Very difficult to differentiate clinically. Treat with silver nitrate. If there is no response after two or three attempts, surgical excision may be necessary.

- Umbilical hernia: Up to 20% of infants, the majority will resolve by 3 yr of life.

- Umbilical polyp: Excision of urachal remnant.

- Urachal remnant: Surgical exploration with excision.
- If urachal cyst is infected, it may be treated initially with broad spectrum antibiotics and drainage.
- Complete excision can be performed once infection has subsided. Risk of malignant degeneration has been reported in the literature.
- Patent urachal duct: Urachal remnant fistula (enteric contents per umbilicus). Surgical exploration with excision needs prompt laparotomy and duct excision to avoid intra-abdominal infection.
- Medial diverticulum: Surgical exploration with excision.
- Urachal carcinoma:
  - Radical cystectomy or partial cystectomy with wide surgical margins and en-bloc resection of urachal remnant extending from bladder to umbilicus, posterior rectus sheath, and all tissue between medial umbilical ligaments is recommended for lower stage, resectable disease.
  - Partial cystectomy may offer a comparable oncologic outcome and less morbidity to radical cystectomy if tumor is completely resected (IC)
  - Failure to resect the umbilicus and positive surgical margins are associated with a worse outcome (IB).
- Bilateral pelvic lymph node dissection
  - Should follow the standard template for bladder cancer.
  - May be useful for staging but does not provide any survival advantage.
  - Surgical resection is particularly well-suited to a laparoscopic or robotic approach with comparable short-term outcomes.

ADDITIONAL TREATMENT

Radiation Therapy

Limited role for unresectable urachal carcinoma

Additional Therapies

- None

COMPLEMENTARY & ALTERNATIVE THERAPIES

- N/A

ONCONEUROLOGY

PROGNOSIS

- Minimal long-term sequelae when managed appropriately.
- Urachal carcinoma:
  - 5-yr overall survival: 27–80%, about 50% for locally advanced disease
  - Less than 20% for metastatic disease
  - 93% for disease confined to the urachus and bladder after surgical resection with bladder preservation
  - 69% for extravesical and perivesical disease after surgical resection with bladder preservation

COMPILATIONS

- Mortality related to the abdominolocalin and the specific treatment modality that is utilized.

CODES

ICD-9

- 753.1 Urachal hernia without mention of obstruction or gangrene
- 759.89 Other specified congenital anomalies
- 772.3 Urachal hemorrhage after birth

ICD-10

- K42.9 Urachal hernia without obstruction or gangrene
- P51.9 Urachal hemorrhage of newborn, unspecified
- O89.8 Other specified congenital malformations

CLINICAL/SURGICAL PEARLS

- In the newborn, a granuloma is the most common cause of persistent drainage.
- Ultrasound is an accurate, minimally invasive imaging modality.
- Umbilical hernias may be seen in up to 20% of infants, but the majority will resolve by 3 yr of life.
- If surgical excision of a urachal remnant is performed, a bladder cuff should be taken if there is involvement of the dome of the bladder.
UNDERACTIVE BLADDER (DETRUSOR UNDERACTIVITY)
Michael J. Amirian, MD
Leonard G. Gomella, MD, FACS

**BASICS**

**DESCRIPTION**
- Detrusor underactivity (DU) often referred to as underactive bladder is a bladder contraction of reduced strength and/or duration.
- Results in prolonged bladder emptying.
- Failure to complete bladder emptying within a normal time span.
- Observed in many neurologic conditions and myogenic failure.
- DU is a common cause of lower urinary tract symptoms (LUTS) in both men and women.
- A wide range of terminology is currently applied in the literature.
- The only formal definition was from the International Continence Society (ICS) in 2002.

**EPIDEMIOLOGY**

**Incidence**
- Present in 9–48% of men and 12–45% of older women undergoing urodynamic evaluation for non-neurogenic LUTS (1).

**Prevalence**
- N/A

**RISK FACTORS**
- Overactive bladder (OAB) may lead to underactive bladder (UAB).
- Diabetes mellitus.
- Aging.
- Acute cerebrovascular accident (CVA).
- Multiple sclerosis (MS).
- Parkinson disease.
- Injury to spinal cord, cauda equina, and pelvic plexus.
- Pelvic surgery.
- Pelvic and sacral fractures.
- Herniated disc.
- Lesions of pudendal nerve.

**PATHOPHYSIOLOGY**
- Diabetic mellitus leading to diabetic cystopathy.
  - Metabolic derangement of Schwann cells.
  - Altered metabolism of glucose.
  - Ischemia.
  - Superoxide-induced, free-radical formation.
  - Impaired axonal transport.
- Alteration in physiology of detrusor smooth muscle cell.
- Aging.
  - Reduction in acetylcholinesterase-positive nerve.
- Reduced parasympathetic innervation.
- CVA.
- Cerebellar defect leading to detrusor areflexia.

**ASSOCIATED CONDITIONS**
- OAB syndrome.

**GENERAL PREVENTION**
- Diabetic patients.
  - Control blood glucose levels.
- Hypertension and hyperlipidemia control.
- Smoking cessation.

**DIAGNOSIS**

**HISTORY**
- History of neurologic injury or medical disorder.
- Recurrent episodes of urinary retention.
- Lower urinary tract symptoms.
  - Straining to urinate.
  - Sensation of incomplete bladder emptying.
  - Diminished and interrupted urinary stream.
  - Urinary urgency.
  - Rely on abdominal straining to urinate.
- Impotence.
  - Overflow, urge, or stress.
- Recurrent urinary tract infections.

**PHYSICAL EXAM**
- May reveal a distended bladder.
- Suspected or known neurologic injury due to pelvic or sacral injury.
- Testing of anal dermatomes.
  - Assessing perianal sensation.
  - Anal sphincter tone.
  - Bulbocavernosus reflex.
- Neurologic testing.
  - Deep tendon reflexes in the lower extremities.
  - Clonus.
  - Plantar responses.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Beyond routine urinalysis and culture, none specific.

**Imaging**
- Upper tract screening if obstruction suspected.

**Diagnostic Procedures/Surgery**
- Urodynamic evaluation (basis of current ICS definition of UAB).
  - Cystometry.
  - Long-curve with lack of sensation.
  - Low detrusor pressure.
  - Electromyography.
  - Usually normal.
  - May show sphincter denervation and uninhibited sphincter relaxation.
- Uroflowmetry.
  - Low peak flow.
  - Prolonged duration of flow.
  - Increased residual urine.

**Pathologic Findings**
- N/A

**DIFFERENTIAL DIAGNOSIS**
- Bladder outlet obstruction.
- Detrusor overactivity.
UNDERACTIVE BLADDER (DETRUSOR UNDERACTIVITY)

**TREATMENT**

**GENERAL MEASURES**
- Limited management available (3)
  - No validated, effective oral drugs, no FDA approved medications. All used off label.
  - Double void or straining to void
  - Avoidance of bladder overdistention
    - Indwelling urinary catheter
    - Intermittent catheterization (preferred)

**MEDICATION**

**First Line**
- α-Adrenergic blockers
  - Alfuzosin
  - Doxazosin
  - Terazosin
- Muscarinic receptor agonists
  - Bethanechol, carbachol
- Choline esterase inhibitors
  - Distigmine (Approved outside of US)

**Second Line**
- Potential therapy
  - Prostaglandin E2
    ◦ Increase detrusor contraction
    ◦ Relax the urethra

**SURGERY/OTHER PROCEDURES**
- Sacral nerve stimulation and intravesical electrical stimulation
  - Potentially beneficial in select patients
- Invasive surgical reconstruction
  - Latissimus dorsi muscle transposition to restore bladder function

**ADDITIONAL TREATMENT**

**Radiation Therapy**

**Additional Therapies**
- Experimental therapeutics:
  - Stem cell therapy
    ◦ Allow weak detrusor to improve contractility
  - Targeted gene therapy

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

**ONGOING CARE**

**PROGNOSIS**
- Good prognosis with appropriate bladder management

**COMPLICATIONS**
- Urinary retention
- Urinary tract infections
- Damage to upper urinary tract

**FOLLOW-UP**

**Patient Monitoring**
- Post-void residual
- Uroflowmetry
- Urinalysis and urine culture

**Patient Resources**
- Underactive Bladder Foundation
  - www.underactivebladder.org

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD9**
- 596.59 Other functional disorder of bladder
- 789.21 Incomplete bladder emptying
- 789.99 Other symptoms involving urinary system

**ICD10**
- N31.8 Other neuromuscular dysfunction of bladder
- R33.8 Other retention of urine
- R39.19 Other difficulties with micturition

**CLINICAL/SURGICAL PEARLS**

The term DU remains surrounded by ambiguity and confusion with a lack of accepted terminology, definition, and diagnostic methods and criteria.

**U**
UNTENDED TESTES (CRYPTORCHIDISM)
Julia S. Barthold, MD, FACS

BASES
DESCRIPTION
• Cryptorchidism, or undescended testes (UDT), is failure of one or both testes to descend or remain descended in a dependent scrotal position.
• Position — Intra-abdominal (10–20%)
• Gubernaculum: Within inguinal canal
• Distal to external ring, including prepubic, pretesticular/gubernaculum, superficial inguinal pouch — True ectopic: Perineal most common
• Subclassifications — Congenital: Testis extrascrotal at birth
— Acquired: Testis extrascrotal at birth but found in an extrascrotal position at a subsequent time (T)
— Delayed diagnosis of primary UDT
— After inguinal surgery
— After spontaneous postnatal descent (recurrent cryptorchidism)
— Vanishing: Blind-ending spermatic vessels and vas deferens in a boy initially diagnosed with UDT

EPIDEMIOLOGY
Incidence
• 2–4% of full-term boys
• Up to 30% of premature boys (<37 weeks gestational age)
• Up to half descend spontaneously in the first 3–6 months of life but some will reascend
• Tectes of premature boys are more likely to descend and may take a year or longer

Prevalence
• 1% of boys at 1 year of age
• Up to 4% of boys undergo orchidopexy for UDT during childhood, presumably related to risk of acquired UDT
• Up to half of boys present with acquired UDT

RISK FACTORS
• Increased incidence in families (2)
— Fathers, brothers, identical twins, monozygotic twins
— Low birth weight: Prematurity or SGA
— Maternal environment
— Retardate testes is a risk factor for acquired UDT in some individuals
— Unilateral — bilateral
— Risk of ascent 7–32% (3)
— Normal testes frequently retractile >6 mo up to puberty, peak at 4–7 y
— Environmental exposure — endocrine and estrogenic compounds in animal models but weak evidence for etiology in human population

Genetics
• Rare variants of INSL3 (or its receptor RXFP2)
• Possible association with AR or ESR1 variants
• Likely polygene/multifactorial

PATHOPHYSIOLOGY
• Failure of complete testicular descent
• Requires normal development and function of the gubernaculum
• Arises from intermediate mesoderm: 1st trimester, enlarges 2nd trimester, regresses and then regresses 3rd trimester—birth
• Requires stimulation by testicular androgens and INSL3

Acquired UDTs are frequently located in the superficial inguinal pouch and in most cases represent primary undescended testes not clinically identifiable until a later age

ASSOCIATED CONDITIONS
• Intra- or extrascrotal persistent vesicovaginal sinus
— 50–90%, increased incidence in younger boys
— Rarely clinically apparent
• Epididymal anomalies
— Long-looping most common
— Detachment of caput
— Atresia rete
— Association with patent processus vaginalis
— Clinical misdiagnosis
• Hypoplasia
• Abdominal wall defects
— Prune Belly (Blind) syndrome; omphalocele; gastrochisis
• Neurologic and musculoskeletal diseases
— Myelomeningocele, cerebral palsy
• Component of over 30 syndromes
• Abnormal Leydig cell function
— Subtle reduction in testosterone (T) and/or increased LH
— Low incidence in non-syndromic UDT
• Disorders of sex differentiation (DSD)
— Usually associated with abnormal urethral and/or penile development
— 46XX congenital adrenal hyperplasia (CAH) with complete penile development; very rare; bilateral non-palpable testes; urgent diagnosis in newborn due to risk of salt wasting

GENERAL PREVENTION
Uncommon

DIAGNOSIS
HISTORY
• Family history of UDT
• History of inguinal hernia and/or surgery
• Maternal exposures or illness during pregnancy
• Birth history: Gestational age and birth weight
• Physical exam:
— Assess scrotal development: May be hypoplastic
— Assess penile development
— Hypoplasia
— Microopenis (<2 SD below mean for age)
— Ambiguous genitalia (DSD)
— Continual periodic exams to assess for spontaneous testicular descent for at least 6 mo
— Assess maintenance of scrotal position
— After spontaneous descent
— Older boys with retractile testes
— Yearly exam, warm room, warm hands, relaxed child if possible
— Upright cross-legged position or supine with legs abducted
— Evidence that a nonpalpable testis is absent
• Intrascrotal “nubbin” = vanishing testis
• Congenital testicular hypoplasia (length ≤1.8 cm) (4)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Bilateral nonpalpable testes: No testing
• Bilateral nonpalpable testes
— Rule out CAH in newborns: Karyotype, electrolytes, 17-OH progesterone
— Hormone levels: T and gonadotropin levels during postnatal surge at 1–3 mo
— Low anti-Müllerian hormone (AMH)
— Abnormal NGS stimulation test

Imaging
• Imaging rarely indicated (5)
— US inaccurate to determine position
— MRI/US more accurate but rarely used
— Potentially useful in selected cases after referral to specialist
— Observe boys with a history of palpable testes
— Rule out to identify spermatic vessels after laparoscopy or abdominal exploration

Diagnostic Procedures/Surgery
• Laparoscopy
— Procedure of choice for localization and determination of status of nonpalpable testes
— Open internal ring: Distal testes likely
— Closed internal ring: No vessels; look for high abdnominal or inguinal testes (image); onamalatic vessels suggests distal “vanishing” testes
— Retroperitoneal exploration to kidney may be required

Pathologic Findings
• Testicular biopsy
— Not standard practice at orchidopexy
• Reduced spermoprosis numbers in UDT
• Reduced sperm (suck dark) spermoprosis most predictive of spermatogenic function
• Leydig cell hyperplasia and/or Sertol cell degeneration—limited data

DIFFERENTIAL DIAGNOSIS
• Nonobstructive UDT
• Vanishing testis: Confirmation of blind-ending spermatic vessels; atretic testis, torsion, or vascular accident
• True agenesis
• Rare; bilateral failure of Wolfian duct development and Müllerian duct regression

TREATMENT
GENERAL MEASURES
• Observe for spontaneous postnatal descent
• Identify clinical hernia or torsion
• Reduce permanent, stable scrotal position by 6 mo of age, then yearly observation
• Observe longer for descent if premature
• Plan surgery at 6–18 mo of age if testis fails to descend to improve testicular growth (6)
• Plan surgery at diagnosis in boys with acquired UDT

MEDICATION
• Hormonal treatment not efficacious (7)
• NGS injections or LHRH nasal spray (not available in the United States)
• Slight benefit over placebo; efficacy 15–20%
• Possible adverse effects: Pigmentation, transient pubic hair, behavior changes, adverse testicular effects
• Inadequate follow-up to rule out recurrence
Surgery/Other Procedures

Alert
In cases of nonpalpable tests, the surgeon must identify the spermatic vessels and confirm that they are blind-ending or associated with an intact testis.

- Surgery vs treatment of choice (3)
- Approach depends on testis palpability
  - Inguinal orchidopexy
    - Standard approach for palpable testis
    - Mobilize testes via inguinal incision
    - High ligation of hemiasac if present
    - Transection of lateral retroperitoneal fascial bands to provide additional length
    - Mobilization performed proximal to spermatic vessels (Penrose nonwoven) rarely needed
    - Higher abdominal counterincision possible if further mobilization needed
  - Placement of testis in sub-Dartos pouch without tension
  - Success rate = 95%
  - Complications: Testicular retraction, testis, cord or nerve injury, bleeding, infection, recurrent hernia (all rare)
  - Primary scrotal orchidopexy (Bland)
    - Increasingly reported as preferred approach for testes distal to external inguinal ring
    - Mobilization of testes and cremasteric muscle/vasa from cord via scrotal incision
    - Standard fixation in subdartos pouch
    - Best for low tests without associated patent processus vaginalis
    - Repair of hernia through scrotal approach along long-term failure rate uncertain and may be higher (18)
  - Similar success and complication rates as compared to inguinal orchidopexy
  - Laparoscopic orchidopexy
    - Procedure of choice for abdominopelvic or high canicular testes near internal ring
    - Laparoscopy for testis localization with two additional lower quadrant ports
    - Mobilization of lateral and medial peritesticular attachments to cord
    - Transection of peritoneum over cord
    - Transection of mobilized testis through existing or neo-inferior and standard fixation in subdartos pouch
    - Success rate = 72–91%
    - Open abdominal orchidopexy
      - High inguinal incision: Potentially more limited access to proximal cord
      - Mobilization similar to laparoscopic approach
      - Success rate = 77–86%
  - Fowler-Stephens orchidopexy
    - One or two-stage procedure via open or laparoscopic approach
    - Required for high tests and/or short spermatic vessels
    - Maintain vascular supply between vas and spermatic vessels
    - Transection of spermatic vessels
    - Success rates 80–94%
  - Orchidectomy of unilateral UDT
    - Consider in high abdominopelvic tests; short vas deferens, hydropsplastic testes, adolescent/young patient
  - Special considerations
    - Testicular biopsy in dysmorphic testis; consider in high abdominal testis, short vas deferens, hypoplastic testes, adolescent/young patient
    - Testicular atrophy; increased risk for abdominal hernia
    - Malignancy: Overall relative risk 2.9–6.5
    - Pregnancy
      - Conception success essentially normal in unilateral, 90%; reduced in bilateral, 30–50%
    - Malgnancy
      - Overall relative risk 2.9–6.5
      - Palpation
        - Femal prolapse/thrombosis; risk may be decreased by prophylactic orchidopexy
      - Testis position may influence histology
      - Abdominal: Seminoma more common
      - Scrotal: Nonseminomatous germ cell tumor more common
  - Complications
    - Testicular atrophy; increased risk for abdominal hernia
    - Torsion risk
      - 10
    - Paternity
      - Testicular position may influence histology
      - Conception success essentially normal in unilateral, 90%; reduced in bilateral, 30–50%
      - Abnormal semen analysis: Highly variable in undescended testes
      - Scrotal: Nonseminomatous germ cell tumor more common

Additional Treatment

Additional Therapies
Adjuvant hormonal therapy may improve germ cell number and/or maturation; long-term efficacy uncertain

Ongoing Care

Prognosis
- Testicular biopsy in dysmorphic testis; consider in high abdominal testis, short vas deferens, hypoplastic testes, adolescent/young patient
- Transection of spermatic vessels
- Required for high testis and/or short spermatic vessels
- High inguinal incision; Potentially more limited access to proximal cord
- Success rates 72–91%
- Similar success and complication rates as compared to inguinal orchidopexy
- Laparoscopy for testis(es) localization with two additional lower quadrant ports
- Mobilization performed proximal to spermatic vessels (Penrose nonwoven) rarely needed
- Higher abdominal counterincision possible if further mobilization needed
- Repair of hernia through scrotal approach along long-term failure rate uncertain and may be higher (18)
- Similar success and complication rates as compared to inguinal orchidopexy

Follow-Up

Patient Monitoring
- Testicular development and position during peripubertal period
- Counseling regarding potential subfertility
- Testicular self-exam
- Counseling regarding potential subfertility
- Microvascular autotransplant requires specific expertise; solitary tests in low risk patients
- Subcutaneous tests placed as last resort to maintain endocrine function

  - Undescended Testes (Cryptorchidism) Images
- Codes
  - ICD-9
    - 752.31 Undescended testes
    - 752.32 Retractile testes
    - 752.89 Other specified anomalies of genital organs
  - ICD-10
    - O37.9 Undescended testes, unspecified
    - O37.11 Abdominal testis, unilateral
    - O55.22 Retractile testes

Clinical/Surgical Pearls
- Spontaneous testicular descent is common in the first 6 mos of life but tests may re-ascend.
- Surgery is the standard treatment.
- Tests that appear to be scrotal at birth can be later diagnosed as cryptorchid with potentially increased risk in retroperitoneal tests.
- Routine tests exams with well-child visits are indicated.

References
URACHAL CARCINOMA
Michael O. Koch, MD, FACS
Andrew D. Strine, MD

DIAGNOSIS

HISTORY
- Increasing incidental detection due to routine use of imaging.
- Often asymptomatic until more advanced.
- Presenting signs and symptoms:
  - Hematuria (most common) or mucosuria
  - Abdominal pain
  - Voiding symptoms or urinary tract infection (UTI)
  - Uterine drainage
  - Urethral mass

PHYSICAL EXAM
- Palpable urachal mass
- Large, fixed mass or concurrent ascites
- Cystoscopy with transurethral biopsy or resection

DIAGNOSTIC TESTS & INTERPRETATION
- Urothelial carcinoma markers:
  - CA-125 and CA 19-9
  - Urine cytology to evaluate for a urothelial malignancy
  - Urinalysis and urine culture to evaluate for infection and metastatic disease.

DIAGNOSTIC EUS & IMAGING
- Abdominal ultrasound:
  - Often obtained during the initial evaluation and in follow-up
- CT or MRI of the abdomen and pelvis with IV and PO contrast:
  - May be elevated in 40–60% of patients
- Bone scan if advanced disease, bony symptoms, or metastasis
- Chest x-ray or CT of chest for staging
- Hematologic and chemistry panels
- Pathologic findings:
  - Favorable (well-differentiated) histology may have a better prognosis than unfavorable (poorly differentiated) histology
  - Absence of urothelial dysplasia or carcinoma
  - Presence of urachal remnant in tumor
  - Presence of urachal remnants in tumor

DIFFERENTIAL DIAGNOSIS
- Vesicourachal diverticulum
- Urachal neoplasms: Adults
  - Benign (very rare): Adenomas, fibromas
  - Malignant: adenocarcinoma
- Vesicourachal fistula from Crohn disease
- Other malignancies:
  - Bladder cancer
  - Kidney cancer
  - Colon cancer
  - Prostate cancer

DIFFERENTIAL DIAGNOSIS
- Urachal remnants, including patent urachus, urachal sinus, cyst, and diverticulum

GENERAL PREVENTION
- None

DESCRIPTION
- Urachal carcinoma is a rare non-urothelial malignancy (almost always adenocarcinoma) usually involving the dome of the bladder due to direct extension from the urachal ligament, the structure from which this tumor arises.
- Rare malignancy
- Less than 1% of all bladder cancers
- Almost exclusively occurs in adults and most commonly in the 4th to 5th decades.
- Adenocarcinoma is the most common histologic subtype.
- Staging is distinct from bladder cancer but not standardized.
- Urachal neoplasms: Adults
  - Urachal remnants
  - Urachal cyst
  - Patent urachus
  - Vesicourachal diverticulum
  - Urachal neoplasm: Adults
    - Benign (very rare): Adenomas, fibromas, fibroadenomas, fibromyxomas, hamartomas
    - Malignant (very rare): less than 0.5% of all bladder cancers

RISK FACTORS
- Nature
- Unknown due to its rarity and often asymptomatic nature
- Prevalence
- 1 in 5 million cases annually
- Incidence
- EPIDEMIOLOGY
- URACHAL CARCINOMA
- Originates from the urachus.
- Serves as a communication between the developing bladder and allantois but becomes a fibrous band by 12 weeks of gestation and is recognized as the median umbilical ligament in adults.
- Composed of urothelium-lined lumen of epithelial origin as well as submucosa and smooth muscle of mesenchymal origin.
- Any layer may undergo a malignant transformation.
- Locally invades into muscularis propria and perivesical fat with demarcation from urothelium.
- Metastasizes to pelvic lymph nodes, lungs, liver, and bone.

ASSOCIATED CONDITIONS
- Urachal remnants, including patent urachus, urachal sinus, cyst, and diverticulum

GENERAL PREVENTION
- None

DIAGNOSTIC PROCEDURES/SURGERY
- Cystoscopy with transurethral biopsy or resection:
  - Evaluate for intravesical invasion, drop metastases, or metastatic disease.
  - Any tumor arising from the dome of bladder should be considered urachal in origin until proven otherwise.
- Percutaneous biopsy may be performed but raises a theoretical concern for seeding the biopsy tract.

PATHOLOGIC FINDINGS
- A majority (50–60%) is adenocarcinoma with glandular features and prostatic mucin.
- Similar immunohistochemistry to colorectal adenocarcinoma (1):
  - Strong reactivity for CDX2 and lack of diffuse nuclear reactivity for α1-antichymotrypsin is more suggestive of urachal origin.
  - No immunohistochemical markers to differentiate adenocarcinoma originating from the urachus and bladder
- Other subtypes:
  - Sarcoma
  - Squamous-cell carcinoma
  - Urothelial carcinoma

PATHOLOGY
- Definitive:
  - Tumor located in the dome of bladder or along midline
  - Demarcation between tumor and urothelium
  - Presence of urachal remnant in tumor
  - Enteric-type pathology
  - Absence of urothelial dysplasia or carcinoma
  - Absence of cystic glandularis and pylorus
  - Favorable (well-differentiated) histology may have a better prognosis than unfavorable (poorly differentiated) historical tumors

DIFFERENTIAL DIAGNOSIS
- Vesicourachal diverticulum
- Urachal neoplasm: Adults
**TREATMENT**

**GENERAL MEASURES**
- Typically manifests as locally advanced or metastatic disease.
- About 20% of patients present with stage 1 (no invasion) or 2 (invasion confined to urachus) disease based on ICD staging system in most series.
- Management is controversial but typically involves surgical resection.
- Chemotherapy and radiation therapy are generally thought to be less effective and reserved for higher stage disease.

**MEDICATION**
- Chemotherapy is typically reserved for unresectable or metastatic disease.
- No standard regimen established.
- Regimens using 5-fluorouracil, cisplatin, and either uracil or gemcitabine and docetaxel are superior to others.
- Median overall survival of 20 months reported in patients with at least a partial response to established disease (48).
- No definitive role for neoadjuvant chemotherapy.

**SECOND LINE**
- No definitive role but often used as an adjuvant therapy for margin- and node-positive disease as well as recurrences.

**SURGERY/OTHER PROCEDURES**
- Radical cystectomy or partial cystectomy with wide surgical margins and en bloc resection of urachal remnant extending from bladder to umbilicus, posterior rectus sheath, and all tissue between medial umbilical ligaments is recommended for lower stage, resectable disease.
- Partial cystectomy may offer a comparable oncologic outcome and less morbidity to radical cystectomy if tumor is completely resected on clinical examination.
- In case of positive surgical margins, additional neoadjuvant chemotherapy and radiation therapy may be beneficial.
- For patients initially staged as locally advanced disease, surgical resection is not recommended, and patients should be considered for neoadjuvant therapy with chemotherapy and radiation therapy, respectively (1).

**ADDITIONAL TREATMENT**
- Radiation Therapy
  - Limited evidence.
  - Occasional use for unresectable or metastatic disease (with chemotherapy) or as an adjuvant therapy for margin- and node-positive disease as well as recurrences.
- Median overall survival of 19.5 mo and 21 mo reported after radiation therapy alone and radiation therapy with chemotherapy, respectively (38).

**ADDENDUM**
- Complementary & Alternative Therapies
  - None

**ONGOING CARE**

**PROGNOSIS**
- Clinical and pathologic staging is the most important predictor of survival (1-3).
- Two staging systems: Chahed and Ashley (6) (See Section II: Urachal Carcinoma Staging Systems).
- 5-yr overall survival rate ranges from 27 to 80%, depending on the series.
- About 50% for locally advanced disease (1-3) (9% for disease confined to the urachus and bladder after surgical resection with bladder resection (5)).
- 89% for extravesical and peri-urachal disease after surgical resection with bladder preservation (10).

**COMPLICATIONS**
- Bleeding
- Infection
- Injury to surrounding organs
- Urinary tract
- Lymphocele
- Postoperative cardiopulmonary complications, including myocardial infarction, deep vein thrombosis, and pulmonary embolism
- Development of recurrent or progressive disease

**FOLLOW-UP**

**Patient Monitoring**
- No standard schedule for oncologic surveillance established.
- Adaptation from bladder cancer
  - Radical cystectomy
  - History and physical examination, electrolytes, serum creatinine, and urine cytology every 3–6 mo for 2 yr and then as clinically indicated
  - Imaging of the chest, abdomen, and pelvis every 6 mo for 2 yr and then as clinically indicated
  - Partial cystectomy
  - Same as above
  - Cystoscopy every 3–6 mo for 2 yr and then at increasing intervals as clinically indicated

**Patient Resources**

**REFERENCES**

**ADDITIONAL READING**

**CLINICAL/SURGICAL PEARLS**
- It is difficult to differentiate between an infection and urachal carcinoma for symptomatic urachal lesions.
- There should be a high clinical suspicion for urachal carcinoma in any adult with an urachal lesion.
- Any tumor arising from the dome of bladder should be considered urachal carcinoma until proven otherwise.
- Surgical management of urachal carcinoma should involve a complete resection of the urachus and umbilicus with wide surgical margins.
URETER AND RENAL PELVIC TUMORS, GENERAL CONSIDERATIONS

Julie M. Riley, MD
Timothy D. Averch, MD, FACS

DESCRIPTION
- Tumors of the ureter and renal pelvis are relatively rare.
- Tumors are most often malignant and account for 5% of all urothelial tumors; most commonly TCC (transitional cell carcinoma), also called urothelial cell carcinoma (UCC).

Epidemiology
- Incidence
  - 1 in 113,333 or ~2400 cases/yr.
  - 7% of all kidney tumors.
- Uterine TCC account for 1 in every 25 upper tract tumors.
- More common in Caucasian population; Asians more often have high-grade tumors.

Prevalence
- Rare.
- Prevalence rate: 6th-7th decade.

Risk Factors
- Smoking: Risk from 2.6-4.0.
- Increases with higher dose and duration.
- History of bladder cancer: 2–25% of patients with bladder cancer develop upper tract TCC.
- Occupational exposure: Similar to bladder cancer; increases with higher dose and duration.
- History of bladder cancer: 2–25% of patients with bladder cancer develop upper tract TCC.
- Smoking: Risk from 4.0 to 5.5.
- Rare benign tumors include inverted papilloma and papilloma.
- Rare malignant tumors include sarcoma, SCC, adenocarcinoma, and carcinocarcinoma.
- Lynch syndrome.
- Black Foot disease: Vasculopathy in Taiwan; arsenic contamination of water.
- Balkan nephropathy: Endemic to Bulgaria, Greece, and Romania.
- Cyclophosphamide: Hemorrhagic cystitis and carcinoma; 9 times increased risk of carcinoma after a dose of 10–15 g over 10 yr; tend to be women.
- Analgesic abuse: All components implicated;
  - Coffee: Minor contribution, relative risk of 1.3.
  - Red meat: Risk from 2.6–4.0.
- Asymmetric azoic urea (color dye, fabrics).
- Naphthalenes, arsine (arsenic) in coal, cigarette smoke.
- High-risk jobs: Autoworkers, leather workers, dry cleaners, dental technicians, beauticians, and painters.
- Coffee: Minor contribution, relative risk of 1.3.
- Analgesic abuse: All components implicated; higher risk with phenacetin abuse.
- Latency of 25 yr.
- Most have no family history of disease.
- Familial clustering exists; difficult to determine if related to environmental factors.
- Low-grade superficial TCC: p16 and p16 loss (chromosome 9p).
- High-grade TCC: p53 loss (chromosome 17p).
- Amplification and overexpression of genes that code for growth factors or their receptors
  - EGFR (chromeosome 7); loss of tumor suppressor gene p16.
- Smoking cessation.
- Avoid or limit chronic analgesia use.
- Avoid exposure to implicated toxins.

PHYSICAL EXAM
- Usually normal.
- Pain or abdominal mass with advanced disease.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging
- Intravenous urogram (IVP): 50–75%.
- Radiolucent filling defect, irregular and continuous with the wall.
- 10–30% show obstruction or non-visualization of the collecting system, which indicates more invasive disease.
- Ascites contralateral kidney for lesion and function.
- Retrograde pyelography (RGP): Better visualization than IVP (>75% accuracy).
- Arteriography, CT angiography.
- Used only if not possible to visualize collecting system via retrograde approach utilizing a percutaneous nephrostomy tube.

Pathologic Findings
- Unilateral or abdominal mass with advanced disease.

Histology
- Urothelial carcinoma of the bladder
- Urothelial carcinoma: Papillary (exophytic).
- Selective cytology barbotage (repeated injection and aspiration of saline): Localize tumor.
- Retrograde pyelography: Better visualization than IVP (>75% accuracy).
- Papillary and squamous cell carcinoma.
- Bucchial glosses.
- High-grade relative risk of bleeding and perforation.
- Selective chemotherapy (image).

Intravenous pyelogram (IVP):
- Used in all cases for staging TCCs due to difficulty in determining the depth of invasion, particularly renal pelvic TCC.
- 10–30% show obstruction or non-visualization of the collecting system.
- Accuracy increases with increasing grade of tumor.

Magnetic resonance imaging (MRI):
- Primary imaging study used for diagnosis and staging of tumors.
- CT urography: Usually normal.

Urine analysis: Hematuria (gross or microscopic).
- Complete blood count: Erythropoietin (EPO) levels.
- Bone marrow biopsy: Metastatic disease.
- Urinary cytology: False negatives.
- Voided specimen: Low sensitivity for upper-tract tumors.

Computed Tomography Urogram (CTU): Primary imaging study used for diagnosis and staging of tumors.
- Magnetic resonance imaging (MRI): Staging.

Antegrade pyelography:
- Used only if not possible to visualize collecting system via retrograde approach utilizing a percutaneous nephrostomy tube.
- Retrograde pyelography: Better visualization than IVP (>75% accuracy).
- Arteriography, CT angiography.
- Used only if not possible to visualize collecting system via retrograde approach utilizing a percutaneous nephrostomy tube.

Intravenous urogram (IVP):
- Used in all cases for staging TCCs due to difficulty in determining the depth of invasion, particularly renal pelvic TCC.
- Radiolucent filling defect, irregular and continuous with the wall.
- 10–30% show obstruction or non-visualization of the collecting system.
URETER AND RENAL PELVIC TUMORS, GENERAL CONSIDERATIONS

DIFFERENTIAL DIAGNOSIS
- Malignant filling defect of the ureter and renal pelvis:
  - TCC, ureteral or renal pelvic: Urothelial carcinoma
  - Adenocarcinoma, sarcoma, angiosarcoma, and carcinosarcoma
  - Renal cell carcinoma (RCC)
- Benign filling defect of the ureter and renal pelvis:
  - Air, gas-forming, infectious, or due to fistula
  - Blood clot
  - Pseudoaneurysm
  - Hemangiomata
  - Inflammatory lesions: Granuloma, miliary peliosis, tuberculous
  - Inverted papilloma
  - Radiolucent calculus
  - Rare benign tumors: Leiomyoma, neurofibroma, cholesteatoma
  - Renal or sloughed papilla
  - Diffuse or focal patterns
  - Protein matrix
  - Mucus: Urinary diversion patients
  - Renal or sloughed papilla
  - Rare benign tumors: Leiomyoma, neurofibroma, cholesteatoma
  - Ureteritis or pyelitis cystica
  - Mucus: Urinary diversion patients
  - Renal or sloughed papilla
  - Rare benign tumors: Leiomyoma, neurofibroma, cholesteatoma
  - Ureteritis or pyelitis cystica
  - Mucus: Urinary diversion patients
  - Renal or sloughed papilla
  - Rare benign tumors: Leiomyoma, neurofibroma, cholesteatoma
  - Ureteritis or pyelitis cystica
  - Mucus: Urinary diversion patients
  - Renal or sloughed papilla

TREATMENT

GENERAL MEASURES
- If positive pathology is the only sign of upper tract TCC, close follow-up is required.
- Standard treatment is surgical for most benign and malignant lesions.

MEDICATION

First Line
- Hikth

Second Line
- Immobilization therapy with BCG or mitomycin not proven to increase survival
- Appears to be safe
- May be used in multiple superficial tumors or bilateral disease
- Difficult to deliver the agent in adequate doses and dwell-time

SURGERY/OTHER PROCEDURES
- Standard treatment is nephroureterectomy (NU) or laparoscopic or open
- Renal sparing surgery indicated: Solitary kidney, bilateral disease, poor function of contralateral kidney, or low grade and stage
- Survival related to stage and grade of tumor rather than to treatment modality
- Radical NU and excision of bladder cuff: 60-90% 5 yr survival (low grade and stage)
- Radical lymphadenectomy not shown to improve survival
- Endoscopic approach to bladder cuff resection has slightly higher rate of bladder recurrence (1)
- Endoscopic treatment (uroscopy (URS) or percutaneous:
  - Indications: solitary kidney, poor renal function, bilateral disease, moderate tumor burden, low-grade, poor surgery candidate
  - Risk of perforation is higher than that in bladder (overall complication rate: 7%)
  - Requires close follow-up due to high recurrence rate (recurrence-free survival ~ 20% at 10 yr (2)
  - Laser ablation in low-grade or multiple tumors
  - Seeding of perinephric space is low (0.03%) (3)
- Segmental ureteral resection: Solitary low-grade upper and mid-ureteral lesions
- Recurrence rate of 6%, higher if multifocal
- Distal ureterectomy and ureteroneocystostomy: Distal, solitary ureteral lesion
- Benign tumors such as fibroepithelial polyp or inverted papilloma: Endoscopic management

ADDITIONAL TREATMENT

Radiation Therapy
Can be used for advanced tumors not amenable to surgery, with decreased efficacy

Additional Therapies
- Neoadjuvant/adjuvant chemotherapy has not been established as in bladder cancer (3)
- Capital therapies have been successful

Complementary & Alternative Therapies
- N/A

ONGOING CARE

PROGNOSIS
- Recurrence site related with more aggressive resection: tumor:
  - 40% recurrence with nephrectomy
  - 32% with nephrectomy plus partial ureterectomy
  - 24% with nephrectomy plus subtotal ureterectomy
  - 12% with NU
  - Prognosis largely unchanged in locally advanced disease
  - Better survival for tumors in renal pelvis than ureteral in T3 or higher disease

COMPLICATIONS
- Obstruction of urinary tract
- Development of metastatic disease

FOLLOW-UP

Patient Monitoring
- Uroscopy with cystoscopy every 3–6 mo for 2–3 yr, then yearly
- 6-mo CT urogram + chest x-ray, then annually
- URS is more sensitive than radiologic techniques for follow-up of upper tract TCC

Patient Resources
- Urology Care Foundation http://www.urolgyhealth.org/urology/index.cfm?artid=39

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Filling Defect, Upper Urinary Tract (Renal Pelvis and Ureter)
- Reference Tables: TTM: Renal Pelvis and Ureter Cancer
- Reference Tables: TTM: Renal Pelvis and Ureter Cancer
- Reference Tables: TTM: Renal Pelvis and Ureter Cancer

CODES

ICD9
- 188.1 Malignant neoplasm of renal pelvis
- 188.2 Malignant neoplasm of ureter

ICD10
- C44.9 Malignant neoplasm of unspecified renal pelvis
- C44.9 Malignant neoplasm of unspecified ureter

CLINICAL/SURGICAL PEARLS
- Universal and renal pelvic tumors are rare
- Management remains surgical with NU being the gold standard
- Endoscopic management is becoming more accepted but the risk of under staging and under grading remains
- Close follow-up is warranted and uroscopy remains the most sensitive surveillance test.
ASSOCIATED CONDITIONS
Pathophysiology
- Chronic inflammation
- Struvite stones
- Xanthogranulomatous pyelonephritis
- Paraneoplastic syndrome
- Chronic infection
- Hypercalcemia

BASICS
DESCRIPTION
- Squamous-cell carcinoma (SCC) of the renal pelvis and ureter is a rare but aggressive tumor characterized by nests of squamous cells with hyperchromatic nuclei and prominent keratin production.
- Most common non-urothelial tumor of the upper urinary tract.

PREVALENCE
- Prevalence unknown due to rarity of tumor.
- 6-15% of all upper tract urothelial cancers
- 0.5-0.8% of all malignant renal tumors
- Most common non-urothelial tumor of the upper urinary tract.

RISK FACTORS
- Prior percutaneous nephrolithotomy
- Analgesic abuse
- Parasitic infection
- Chronic pyelonephritis or pyonephrosis
- Struvite stones
- Genitourinary tuberculosis
- Presumed that chronic irritation of urothelium to be associated with chronic infection and inflammation

DIAGNOSIS
HISTORY
- History of chronic renal infections or stones
- Vague abdominal or flank pain
- Gross hematuria
- Lab:
  - Hematuria
  - Pyuria
  - Serum creatinine may be elevated due to tumor infiltration, obstruction, chronic infection, or scarring
  - Paraneoplastic syndrome which may resolve following resection includes:
    - Hypercalcemia
    - Thrombocytosis
    - Keratin pearls and intercellular bridges may not be apparent in advanced cases

DIAGNOSTIC TESTS & INTERPRETATION
- Imaging:
  - Diagnosis suggested (but not definitive) with radiologic imaging
  - Excretory imaging useful (including intravenous pyelogram, CT urogram) and may demonstrate:
    - Filling defect
    - Solid mass w/ or w/o calcifications
    - Hydronephrosis
  - Oncologic pathology confirmed, CT or MRI/MRA necessary for surgical planning
  - Vascular anatomy
  - Presence of metastases
  - Evaluation of contralateral renal unit
  - Size and extent of tumor

Pathologic Findings
- Most moderately or poorly differentiated
- Gross (180):
  - Nonspecific symptoms:
    - Local symptoms more common than those with TCC
  - Nonspecific symptoms:
    - Anorexia
    - Lethargy
    - Weight loss
  - Physical exam:
    - Flank or abdominal mass may be present with advanced disease
    - May have calcifications
    - Definitive diagnosis confirmed following nephroureterectomy (see TREATMENT)

DIFFERENTIAL DIAGNOSIS
- Primary renal neoplasms
  - Renal cell carcinoma
  - Urothelial cancer
  - Wilms tumor

- Secondary renal neoplasms
  - Metastasis to kidney
  - Metastasis to kidney (breast, lung, and others)

- Benign renal masses
  - Xanthogranulomatous pyelonephritis
  - Rare form of chronic pyelonephritis
  - Angiomyolipoma
URETER AND RENAL PELVIS, SQUAMOUS CELL CARCINOMA

TREATMENT

GENERAL MEASURES
Surgery (nephroureterectomy) is mainstay of treatment (3)[C]

MEDICATION
First Line
Medical therapy not effective although some patients require broad-spectrum antibiotics in the setting of concurrent infection

Second Line
N/A

SURGERY/OTHER PROCEDURES
Referent standard treatment is surgical excision (radical nephroureterectomy with excision of bladder cuff) (3)[C]
Role of retroperitoneal lymph node dissection controversial
For those patients with infection, pre- and post-operative antibiotics may be required

ADDITIONAL TREATMENT
Radiation Therapy
Occasionally used for adjuvant treatment following surgery; however shown to have little benefit (1)[C]

ADDITIONAL TREATMENT
Complementary & Alternative Therapies
No complementary therapies have shown benefit

ONGOING CARE

PROGNOSIS
• Generally poor if found at advanced stage
  – Median survival of 7–14 mo postoperatively (2–4)[C]
  – Median 5-yr survival: 7.7% (3)[C]
• Tumor stage at diagnosis most important for prognosis (3)[C]
• Grade has been found to add little value (3)[C]

COMPLICATIONS
• Renal insufficiency or failure
  • Metastatic disease (3)[C]
  • Regional lymph nodes
  • Liver
  • Bone

FOLLOW-UP
Patient Monitoring
• Limited data for patient monitoring
• Similar to TCC of upper tract
  – Urine cytology and cystoscopy every 3–4 mo for first 2 yr
  – Value of cystoscopy questionable due to low number of concurrent bladder cancers
  – Metastatic workup every 6–12 mo, depending on stage
    – Chest imaging
    – CT abdomen/pelvis
  – Monitor renal function periodically

ADDITIONAL READING

CLINICAL/SURGICAL PEARLS
• SCC of upper tract is the most common non-urothelial cancer of the renal pelvis and ureter
• A few symptoms manifest, but once hematuria and pain present, often advanced stage.
• Usually presents as advanced disease and has poor prognosis at this stage.
• Nephroureterectomy is standard of care with chemotherapy and radiation of limited benefit.

ICD-9
189.1 Malignant neoplasm of renal pelvis
189.2 Malignant neoplasm of ureter

ICD-10
C65.1 Malignant neoplasm of right renal pelvis
C65.9 Malignant neoplasm of unspecified renal pelvis
C66.9 Malignant neoplasm of unspecified ureter
URETER AND RENAL PELVIS, UROTHELIAL CARCINOMA

Emma F.P. Jacobs, MD
Michael O. Koch, MD, FACS

DESCRIPTION
Urothelial carcinoma (formerly known as transitional cell carcinoma or TCC) is an epithelial neoplasm of the urinary, renal pelvic, and calyces.

Epidemiology
Incidence
- 5–10% of renal tumors are renal pelvis TCC
- 2–5% of urothelial tumors occur in the upper urinary tract (UUT)
- Peak incidence of 10 per 100,000 yr in 75–79 age group
- Male age at presentation is 65, seldom appear before age 40 yr.
- Incidence is increasing.

Prevalence
Poor data available given rarity of condition.

Prevalence
Incidence
EPIDEMIOLOGY

DESCRIPTION
Urothelial carcinoma (formerly known as transitional cell carcinoma or TCC) is an epithelial neoplasm of the urinary, renal pelvic, and calyces.

Clinical Features
- Male
- White
- Typically bilateral, multifocal, low-grade
- Renal pelvic TCC
- Sites: Ureter (50–80% present with hematuria)
- Diagnosis
- General measures
- Smoking
- Cyclophosphamide
- Radiographic imaging
- Voided urine cytology: Low sensitivity for low-grade

RECOMMENDATIONS
- Pap screening of UUT TCC is difficult due to the limited size of biopsy specimens.
- Staging is predicted by biopsy grade.
- Tumor grade may be a more important prognostic factor than pathologic stage in UUT.
- Sending all biopsies for cytopathologic exam can improve the diagnostic yield (full block).

DIAGNOSTIC TESTS & INTERPRETATION
- Vein analysis: Gross or microscopic hematuria
- Electrolytes, LFTs: normal in absence of urinary obstruction, or metastatic disease
- Voided urine cytology: Low sensitivity for low-grade TCC, better for high-grade, CIS

DIAGNOSTIC PROCEDURES/SURGERY
- IVP:—traditional diagnostic study largely replaced by CT Urograms
- Retrograde pyeloureterography
- Computerized tomographic urography (CTU):—3D reconstruction image quality is equivalent to CT Urograms
- Intravenous urogram (IVU) or intravenous pyelogram

TREATMENT

GENERAL MEASURES
- Topical therapy—BCG, mitomycin, thiotepa
- Fungal infection
- Intravesical urothelial neoplasms
- General measures

BASICS
Urothelial carcinoma (formerly known as transitional cell carcinoma or TCC) is an epithelial neoplasm of the upper urinary tract (UUT). Urothelial carcinoma, also known as urothelial cancer, bladder cancer, or transitional cell carcinoma (TCC), is the most common type of urinary tract cancer in adults. It is characterized by the presence of abnormal cells lining the urinary tract, typically in the bladder or ureter. The condition can be associated with various risk factors, including smoking, cyclophosphamide use, and occupational exposure to certain chemicals. The incidence of urothelial carcinoma is increasing, and it is more common in men than in women. Diagnostic procedures such as cystoscopy, retrograde pyelography, and computerized tomographic urography (CTU) are used to identify and stage the disease. Treatment options include surgery, chemotherapy, and immunotherapy, with the goal of preserving renal function and improving quality of life.
URETER AND RENAL PELVIS, UROTHELIAL CARCINOMA

SURGERY/OTHER PROCEDURES
- Open radical nephroureterectomy (RNU) with en-bloc excision of peri-ureteric and peri-bladder cuff:
  - Traditional treatment
  - Provides adequate surgical margins, local control, removes need for bilateral ureteroscopy
- Role of lymphadenectomy is unclear
- Laparoscopic RNU:
  - Equivalent disease-specific and overall survival compared to open RNU
- Skin incision positioned to allow for distal ureteral reimplantation
- Nephron-sparing surgery—For locally contained low-grade disease or high-grade disease with overwhelming concern for loss of renal function
- Segmental ureterectomy:
  - Used for noninvasive low-grade TCC of proximal or mid ureter too large for endoscopic ablation
  - Distal ureterectomy with reimplantation
- Used for distal ureteral TCC too large for endoscopic ablation or high-grade TCC
  - Endoscopic treatment:
    - Indications include solitary kidney, bilateral disease, poor renal function, moderate tumor burden, low-grade disease, high-risk surgical candidates
    - Retrograde or percutaneous antegrade approach
    - Tumor biopsy with cold-cup or basket
    - Treatment techniques include electrocautery, fulguration, laser ablation
    - Recurrence rate: 33% for unilateral TCC, 31% for renal pelvis TCC

ADDITIONAL TREATMENT
Radiation Therapy
Possible role for adjuvant radiation after complete excision. Studies have been small and collectively inconclusive.

Additional Therapies
- Consider systemic chemotherapy for high-stage or node-positive disease in patient with adequate renal function
  - Standard chemotherapy agents used for bladder cancer
  - Methotrexate, vinblastine, doxorubicin, and cisplatin (MVAC)
  - Gemcitabine and cisplatin

Complementary & Alternative Therapies
- No accepted therapy

ONGOING CARE
PROGNOSIS
- Overall 5-yr survival based on grade:
  - Grade 1–2: 40–87%
  - Grade 3–4: 0–33%
- 5-yr survival based on stage:
  - Stage T1: 75–85%
  - Stage T2: 43–75%
  - Stage T3: 16–33%
  - Stage T4: 0–5%

COMPLICATIONS
- Local obstruction, metastatic dissemination

FOLLOW-UP
Patient Monitoring
- If RNU is performed:
  - Cystoscopy and cytology every 3 mo for 2 yr, then every 6 mo for 2 yr, then yearly thereafter (VP or CTU) yearly
- If nephron-sparing surgery is performed:
  - Ureteroscopy, surveillance, and cytology every 3 mo until tumor-free, then every 6 mo thereafter (VP or CTU) yearly

Patient Resources
Urology Care Foundation http://www.urologyhealth.org/urologyvideo/ch/7articleid=9

REFERENCES

ADDITIONAL READING

CODES
ICD9
- 189.1 Malignant neoplasm of renal pelvis
- 189.2 Malignant neoplasm of ureter

ICD10
- C65.9 Malignant neoplasm of unspecified renal pelvis
- C66.9 Malignant neoplasm of unspecified ureter

CLINICAL/SURGICAL PEARLS
Due to the high distal recurrence rate (33–55%), it is prudent to ensure that the entire ureteral stump is removed at the time of radical nephroureterectomy (RNU).
URETER, INTRAOPERATIVE INJURY

John M. Barry, MD, FACS
Daniel D. Dugi III, MD

DESCRIPTION

• Intraoperative injury to the ureter can occur during open, laparoscopic, or endoscopic surgery
• May be direct laceration, suture ligation, crush injury, thermal injury, or devascularization
• Lower 1/3 of ureter (within the pelvis) is most commonly injured
• Injury may cause obstruction of kidney if ureter is ligated or urinary extravasation if lacerated
• Due to the proximity to the vagina, some injuries may result in ureter-vaginal fistula

ASSOCIATED CONDITIONS

• Radiation therapy, cancer, prior pelvic surgery
• Ureteral stones

RISK FACTORS

• Women with leakage of urine per vagina
• Symptoms of urinary tract infection

EPIDEMIOLOGY

Incidence

• Most series report 1–5% of pelvic surgeries; highest rates among radical hysterectomy cases (18)
• 1–5% of ureteroscopic surgeries (19)
• Approximately half of iatrogenic injuries occur during gynecologic surgery (20)

Prevalence

N/A

HISTORY

Most ureteral injuries are not recognized preoperatively (16). Postoperative recognition is essential to prevent or recognize an intraoperative injury.

PHYSICAL EXAM

• Intravenous or intravesical administration of an indigo carmine or methylene blue dye helps identify ureteral injury if dye is seen in the operative field after intravenous or intravesical administration.
• Contrast studies are critical for postoperative diagnosis. CT scan with IV contrast and excretory phase imaging may show urine extravasation or a urinoma.

DIAGNOSTIC PROCEDURES/SURGERY

Indigo carmine or methylene blue may help identify ureteral injury if dye is seen in the operative field after intravenous or intravesical administration.

Diagnostic Procedures/Surgery

• Indigo carmine or methylene blue dye is administered prior to placement of a ureteral stent. The dye should be administered to both ureters if bilateral ureteral stenting is needed.
• Injuries above the true pelvis (proximal ureter) may be repaired with direct anastomosis if proximal and distal mobilization allows tension-free repair.
• Injuries within the pelvis are usually best repaired by direct reimplantation into bladder, with psoas hitch, if necessary (15).
• Partial-thickness, clean lacerations may be closed by direct reapproximation.
• Ligation injuries: Remove suture and inspect for surrounding tissue has not be devascularized.
• Injuries above the true pelvis (proximal ureter) may be repaired with direct anastomosis if proximal and distal mobilization allows tension-free repair of healthy, well-vascularized edges.
• More complex repairs, such as flap, trans-ureteral-reimplantation, or ureteral patch should be undertaken cautiously in the acute setting.
• In unstable patients, the ureter may be left ligated and a percutaneous nephrostomy tube placed postoperatively to drain the kidney.
• It is best to leave an indwelling ureteral stent postoperatively.

DIAGNOSIS

History

• Indigo carmine or methylene blue dye may help identify ureteral injury if dye is seen in the operative field after intravenous or intravesical administration.
• Partial-thickness, clean lacerations may be closed by direct reapproximation.
• Injuries above the true pelvis (proximal ureter) may be repaired with direct anastomosis if proximal and distal mobilization allows tension-free repair of healthy, well-vascularized edges.
• More complex repairs, such as flap, trans-ureteral-reimplantation, or ureteral patch should be undertaken cautiously in the acute setting.
• In unstable patients, the ureter may be left ligated and a percutaneous nephrostomy tube placed postoperatively to drain the kidney.
• It is best to leave an indwelling ureteral stent postoperatively.

Medication

First Line

Indigo carmine or methylene blue may help identify ureteral injury if dye is seen in the operative field after intravenous or intravesical administration.

Second Line

SUTURES

SURGERY/OTHER PROCEDURES

• Indigo carmine or methylene blue dye may help identify ureteral injury if dye is seen in the operative field after intravenous or intravesical administration.
• Partial-thickness, clean lacerations may be closed by direct reapproximation.
• Injuries above the true pelvis (proximal ureter) may be repaired with direct anastomosis if proximal and distal mobilization allows tension-free repair of healthy, well-vascularized edges.
• More complex repairs, such as flap, trans-ureteral-reimplantation, or ureteral patch should be undertaken cautiously in the acute setting.
• In unstable patients, the ureter may be left ligated and a percutaneous nephrostomy tube placed postoperatively to drain the kidney.
• It is best to leave an indwelling ureteral stent postoperatively.
Injuries recognized postoperatively:
- If recognized in the first few days to 1 week after initial injury, operative repair is recommended
- If recognized later, reoperation after resolution of surgical inflammation 6 weeks or more postoperatively is recommended (2)
  - Retrograde ureteropyelography is helpful in diagnosing ureteral injury and allows for attempt at ureteral stent placement in low-grade injuries (2)
  - Small lacerations or partial ligations may heal after a period of ureteral stenting
- Peritoneal nephrostomy drainage is recommended if ureteral stenting is not possible. This also allows attempt at antegrade ureteral stent placement
  - Optimal duration of ureteral stenting is not known, but 6 wk is reasonable
  - Percutaneous drainage of urinoma is necessary if the urinoma is infected, symptomatic, or does not decrease in size after successful renal drainage is established

Additional Treatment
Radiation Therapy
N/A
Additional Therapies
N/A
Complementary & Alternative Therapies
N/A

Ongoing Care

Prognosis
- Intraoperative recognition and repair usually prevents complication of urine extravasation or renal obstruction
- Ureteroneocystostomy for distal ureteral injuries has an excellent prognosis. Proximal ureteral repair have a higher risk of long-term complications because of compromised blood supply
- Patients who have delayed recognition of injuries have higher rates of complications and more procedures needed to resolve injury than those with injuries recognized intraoperatively (2)

Complications
- Urine leakage from a ureteral injury may lead to urine extravasation and renal obstruction
- Extravasated urine may cause irritation of the intestines and peritoneum and result in pain and/or ileus
- Urinary stricture and renal obstruction may cause loss of renal function
- Ureterovaginal fistula
- Complications of ureteral injury and repair may result in nephrectomy

Follow-Up
Patient Monitoring
- Perform follow-up imaging of the kidney to assure no obstruction from ureteral stricture. Renal ultrasound can evaluate for hydronephrosis and urinoma and has no radiation
- Intravenous imaging (i.e., ExU, CT urography, retrograde ureterography with hydrodynamic washout) may be indicated in complex circumstances or when hydronephrosis is found by ultrasound.

Patient Resources
N/A

See also (Topic, Algorithm, Media)
- Ureter, Stricture
- Ureter, Trauma

ICD9
- 867.2 Injury to ureter, without mention of open wound into cavity
- 997.5 Urinary complications, not elsewhere classified
- 998.2 Accidental puncture or laceration during a procedure, not elsewhere classified

ICD10
- N99.71 Acc pnctr & lac of a GU sys org during a GU sys procedure
- N99.81 Other intraoperative complications of genitourinary system
- S37.10XA Unspecified injury of ureter, initial encounter

Clinical/Surgical Pearls
- During mobilization of the ureter, avoid "skeletonization" and include periureteral tissue to better preserve blood supply
- Repair ureteral injuries and avoid nephrectomy unless the repair will place the patient at risk
- A cystostomy allows easy access to the ureteral orifice to aid in stent placement during open surgery.
URETER, OBSTRUCTION

Jennifer E. Heckman, MD, MPH
Stephen Y. Nakada, MD, FACS

BASICS

DESCRIPTION
- Ureteral obstruction can be anatomic or functional blockage of the ureter and further classified as:
  - Congenital or acquired
  - Acute or chronic
  - Benign or malignant
  - Intrinsic or extrinsic
  - Unilateral or bilateral
- Impact of obstruction dependent on:
  - Degree and duration of obstruction
  - Baseline renal function
  - Potential for reversibility
- Associated definitions:
  - Hydronephrosis
  - Dilation of renal pelvis and calyces
  - Can occur with or without obstruction (obstruction may be anywhere in urinary tract, from urethral meatus to calyces)
  - Hydroaureterohydronephrosis
  - Dilation of renal pelvis, calyces, and ureter
  - Obstructive uropathy
  - Impedance to urinary flow anywhere in urinary tract
  - Obstructive nephropathy
  - Renal parenchymal damage from urinary tract obstruction
- Urinary tract infection and sepsis may be superimposed

EPIDEMIOLOGY

Incidence
- No data available in unselected populations
- Etiology-dependent

Prevalence
- Can occur during fetal development, childhood, or adulthood
- Occurrence increases with increasing age
- Unilateral > bilateral
- Hydronephrosis may be surrogate marker for obstruction
- Overall prevalence in autopsy series: 3.1% (1)

RISK FACTORS
- Renal or ureteral calculus
- Malignancy
- Hematopoietic
- Infection
- Trauma
- Radiation

Genetics
- No specific associated familial or hereditary disorder, but cause may be congenital
- 10–50% of children with end-stage renal disease have obstructive uropathy associated with congenital anomalies

PATHOPHYSIOLOGY
- Ureteral obstruction results in elevated intravesical pressure
- With increased pressures in proximal tubule and Bowman capsule, glomerular filtration rate (GFR) decreases
- Persistent obstruction leads to decreased renal blood flow and subsequent ischemia and nephron loss
- Three major points of anatomic ureteral narrowing:
  - Ureteropelvic junction (UPJ)
  - Where ureter crosses iliac vessels
  - Ureterovesical junction (UVJ)

ASSOCIATED CONDITIONS
- Congenital
  - Vescoureteral reflux
  - Megacephaly
  - UPJ obstruction
- Structural
- Inflammatory
  - Abscess
  - Amyloidosis
  - Tuberculosis
- Malnutrition
- Malignancy
  - Urinary cancer
  - Bladder cancer
  - Metastatic disease
- Vascular
  - Anastomoses
  - Abnormal vessels
- Other
  - Urolithiasis
  - Pregnancy
  - Trauma
- Reconstructive/urologic disease
  - Ureteral obstruction

GENERAL PREVENTION
Dependent on underlying etiology

DIAGNOSIS

HISTORY
- Presentation reflects underlying etiology
- May be asymptomatic
- Acute obstruction may cause significant pain
  - Upper tract:
    - Flank pain (renal colic)
    - Pain radiating to abdominopelvic region (renal obstruction)
  - Lower tract:
    - Distal obstruction:
      - Pain, hematuria, pyuria, or crystals
    - Ureterovesical obstruction:
      - Urinary straining
    - Abdominal tenderness
  - Hypertension possible
  - Pyrexia if associated with infection

DIAGNOSTIC TESTS & INTERPRETATION

Imaging
- Renal ultrasound
  - Screening test of choice (inexpensive, no radiation or contrast required)
  - Can identify parenchymal thickness, urinary tract dilation
- Intravenous pyelogram (IVP)
  - Delineate collecting system anatomy
  - Requires contrast (limit use in renal insufficiency)
  - Low false-positive rate
- Retrograde pyelogram
  - Define collecting system anatomy
  - Requires contrast (limit use in renal insufficiency)
- Urography
  - Provides anatomic and functional information
  - Low false-positive rate
  - Requires contrast (limit use in renal insufficiency)
  - Requires contrast (limit use in renal insufficiency)

Lab
- Serum studies:
  - Creatinine
  - Often elevated, though may be normal in setting of normal contralateral kidney
  - Electrolytes
  - Urine studies:
    - Uretal culture:
      - May see hematuria, pyuria, or crystals
    - May see elevated pH secondary to nephron destruction in affected kidney
    - Urine electrolytes

PHYSICAL EXAM
- Renal ultrasound
  - Screening test of choice (inexpensive, no radiation or contrast required)
  - Can identify parenchymal thickness, urinary tract dilation
  - Intravenous pyelography (IVP)
  - Delineate collecting system anatomy
  - Requires contrast (limit use in renal insufficiency)
  - Low false-positive rate
  - Requires contrast (limit use in renal insufficiency)
  - Requires contrast (limit use in renal insufficiency)

Diagnosis Procedures/Surgery
Perform Whitaker test (pressure flow test) in equivocal cases

Pathologic Findings
- Gross
  - Renal papillemal dilatation
  - Papillary infarct
- Histological
  - Cortical and medullary atrophy
  - Parietal edema
  - Enlarged, edematous proximal tubular obstruction
- Microscopic
  - Urinary tract obstruction
    - Collecting duct, tubule, and lymphatic dilatation
  - Intestinal edema and fibrosis
  - Tubular basement membrane thickening

548
URETER, OBSTRUCTION

Differential Diagnosis
- Intrinsic:
  - Urolithiasis
  - Striated papilla
  - Malignancy
- Extrinsic:
  - Adenomyopic tumors
  - Retroperitoneal fibrosis
  - Pregnancy
  - Vascular anomalies
  - Aneurysm of ureter (aortic, caval)
- Systemic disease (congenital or acquired)
- Inflammatory disorder
- Neuromuscular dysfunction
- In children:
  - Potter (ureteral valves [nuke])
  - UPI obstruction
  - UO obstruction
  - Ectopic ureter
  - Megaureter
  - Ureterolysis

TREATMENT
Urinary obstruction, if high-grade, bilateral, or associated with renal failure or infection warrants urgent decompression

GENERAL MEASURES
- Early recognition important in preventing irreversible renal functional impairment
- Management of acute obstruction directed at establishing drainage
- After initial stabilization and drainage, determine location and cause of obstruction
- Unilateral obstruction does not always require intervention
- May observe (e.g., terminally ill patient with normal contralateral kidney, normal serum Cr, and electrolytes)
- Supportive care (pain control, correction of electrolyte abnormalities)

MEDICATION
First Line
- Part management (oral or parenteral)
  - 1st line: Non-steroidal, anti-inflammatory medications
  - 2nd line: Narcotic medications

Second Line
- NSAIDs

SURGERY/OTHER PROCEDURES
- Renal drainage:
  - Nephrostomy
  - Retrograde ureteral stent placement
  - Placement of an indwelling ureteral stent in ureteral obstruction
  - Techniques depend on clinical scenario (e.g., stent preferred if uncorrectable coagulopathy, stent not as effective for extrinsic ureteral obstruction)
- After management of acute obstruction, definitive management directed by cause, renal function, and patient condition
- Urolithiasis:
  - Ureteroscopy with laser lithotripsy
  - Extracorporeal shockwave lithotripsy
  - Calculus extraction, percutaneous nephrolithotomy (location and calculus dependent)
- UPI obstruction
  - Open or laparoscopic pylonephrotomy
  - Vascular lesions (e.g., aortic aneurysm)
  - May require urgent operative intervention
- May consider nephrectomy if affected kidney contributes <10% to global renal function

ADDITIONAL TREATMENT
Radiation Therapy
- None

Additional Therapies
- None

Ongoing Care
Prognosis
- Progressive renal damage may occur
- Poor if untreated bilateral obstruction

Complications
- Acute renal failure
- Postobstructive diuresis in setting of bilateral ureteral obstruction

Follow-Up
Patient Monitoring
- Serum osmolality
- Serum electrolytes
- Renal ultrasound
- Nuclear renal scan

Patient Resources
NIDDK: Unilateral hydronephrosis

Additional Reading

See Also (Topic, Algorithm, Media)
- Bladder, Renal and Genitourinary, General Considerations
- Filling Defect, Upper Urinary Tract (Renal Pelvis and Ureter)

ICD9
- 593.3 Obstructive defects of renal pelvis and ureter
- 753.20 Unspecified obstructive defect of renal pelvis and ureter

ICD10
- N13.3 Hydronephrosis
- N13.3 Stenosis or narrowing of ureter
- N13.3:20 Unspecified obstructive defect of renal pelvis and ureter

ICD11
- N13.3 Hydronephrosis: Renal pelvis and ureter
- N13.3:20 Unspecified obstructive defect of renal pelvis and ureter

Clinical/Surgical Pearls
- Hydronephrosis is an anatomic, not functional, diagnosis.
- Renal scan best study if renal function adequate
- Bilateral ureteral obstruction, unilateral obstruction in a solitary kidney, and ureteral obstruction associated with renal failure or infection warrant immediate renal drainage.
## URETER, TRAUMA

Brad Figler, MD
Hunter Wessells, MD, FACS

### BASICS

**DESCRIPTION**
- Due to its mobility, narrow diameter, and protected location, ureteral injury from external trauma is rare.
- 75% of ureteral injuries are iatrogenic; 18% from blunt trauma and only 7% from penetrating trauma (1).
- Iatrogenic injury is discussed in detail elsewhere (see Section II: “Ureter, Intraoperative Injury”).

**EPIDEMIOLOGY**

**Incidence**
- Ureteral injuries represent < 1% of all genitourinary injuries caused by violent trauma.
- Typically result from gunshot wounds.
- Blunt trauma and stab wounds responsible for ~ 20% of ureteral injuries.
- Typically occurs concomitant with other injuries (chest, retroperitoneal, pelvic).

**Prevalence**
- Unknown

**RISK FACTORS**
- Penetrating injury to the abdomen and low chest.
- Flank or lower abdominal tenderness.
- Gross hematuria.
- Abdominal distention.
- Flank pain.
- Nausea/vomiting.
- Fever.

**Genetics**
- Unknown

**PATHOPHYSIOLOGY**
- Direct injury from penetrating object.
- Stretching of ureter as a result of hyperextension of the body.
- Compression against transverse process as a result of rapid deceleration.
- American Association for the Surgery of Trauma (AAST) Injury Scoring Scale for ureteral trauma (2).

**DIFFERENTIAL DIAGNOSIS**
- Other urinary tract trauma.
- Kidney.
- Bladder.
- Nephrostomy tube.
- Ureteral stenting or autotransplantation.

**Associated Conditions**
- Small bowel injury.
- Colon injury.
- Point injury.
- Bladder injury.

**GENERAL PREVENTION**
- Avoid high-risk activity.
- Seatbelt use.

### DIAGNOSIS

**HISTORY**
- Requires a high index of suspicion.
- History of urologic condition or surgery.
- Mechanism of injury:
  - Hyperextension
  - Deviation
  - Fall from height
  - Primary location of impact
- Presence of hematuria
  - Uirit
  - Duration
- Flank pain
- Fever
- Nausea/vomiting

**PHYSICAL EXAM**
- Enlargement wounds.
- Gross hematuria.
- Flank or lower abdominal tenderness.
- Flank bulge.
- Abdominal distention.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- Hematuria is unreliable; absent in 26% of cases (3).
- Creatinine may (rarely) be elevated due to extravasation and reabsorption of urine or obstruction.

**Imaging**
- Demonstration of extravasation of contrast is the gold standard for the diagnosis of ureteral trauma.
- Retrograde pyelography is most reliable for diagnosing ureteral injury, often impractical in trauma patient.
- CT with IV contrast and delayed images is an acceptable alternative. Most trauma patients have C T scans before being taken to the OR emergently.
- On table “one-shot” IVP is sometimes performed in the operating room.
- Administration of 2 ml/kg IV contrast with on table x-ray plain film after 10 min.

**Pathologic Findings**
- Microvascular injury from high-velocity missiles or thermal injury can extend up to 2 cm beyond evidence of gross injury.

**TREATMENT**

**GENERAL MEASURES**
- Initial management of the trauma patient employs primary survey, resuscitation stabilization, and primary survey, resuscitation stabilization, and trauma patient.
- Nondistended or - Nephrostomy tube.
- Some common options for complete ureteral injury:
  - Upper third: Uretero-ureterostomy or Blandy cystoplasty.
  - Middle third: Uretero-ureterostomy or Blandy flap.
  - Lower third: Direct reimplantation or psoas hitch.
- Complete ureteral loss: Neobladder or ileal interposition as a delayed procedure.

**ALER**
- Delay in diagnosis of ureteral injury is a major contributing factor to morbidity in a trauma patient.

### Associated Conditions

</tr>
<tr>
<td>4</td>
<td>Complete tear &gt; 2 cm of devascularization</td>
</tr>
</tbody>
</table>

**Medial extravasation of contrast at the level of the UPJ, suggestive of UPJ or renal pelvis injury.**

- Ureters should opacify to the level of the bladder on delayed imaging to be diagnostic.
- Access for foreign bodies, fluid collection, and hydrothorax.
- Ultrasound is generally not useful, except in demonstrating a urinoma or hydrothorax.
- MRI not used acutely in the trauma setting.

**Diagnosis Procedures/Surgery**
- Retrograde pyelogram: Useful to verify presence or absence of suspected injury.
- Ureteral exploration is highly sensitive.
- Probe wounds to establish trajectory.
- Bladder
- Nephrostomy tube.
- Ureteral stenting or autotransplantation as a delayed procedure.

**Alert**
- Absence of hematuria does not exclude ureteral injury. Clinical suspicion should guide investigation.

- Duration.
- Onset.
- Primary location of impact.
- Fall from height.
- Deceleration.
- Hyperextension.
**MEDICATION**

**First Line**
- Methylene blue and indigo carmine may help identify the site of a ureteral perforation or transection (see Section I: “Ureter, Intraoperative Injury”).

**Second Line**
- Furosemide (20–40 mg IV) can be administered to speed indigo carmine excretion.

**SURGERY/OTHER PROCEDURES**

- Principles of ureteral repair include:
  - Careful mobilization
  - Preserve adventitia
  - Avoid electrocautery
  - Debridement of nonviable tissue to bleeding
  - Sphincterotomy
  - Tension-free
  - Watertight
  - Mucosa to mucosa
  - Spatulated
  - Debridement of nonviable tissue to bleeding

- Advanced techniques typically not appropriate in the unstable patient.
  - Bowel interposition
  - S37.19XA Other injury of ureter, initial encounter
  - S37.10XA Unspecified injury of ureter, initial encounter
  - N99.81 Other intraoperative complications of open wound
  - 997.5 Urinary complications, not elsewhere classified
  - 867.3 Injury to ureter, with open wound into cavity

**PROGNOSIS**

- Long-term outcomes not reported in this population, but long-term results of ureteral surgery are excellent (4).

**COMPLICATIONS**

- Delayed complications include:
  - Retained ureteral stent
  - Ureteral stricture
  - Prolonged leakage

- Hydronephrosis

**FOLLOW-UP**

**Patient Monitoring**
- Check if stone in at least 2 days after abdominal injury. If consistent with stone, consider removing.
- Stent removal 4–6 wk
- Renal scintigraphy with Lasix 2–4 wk after stent removal to document function/drainage

**Patient Resources**
- Ureter Trauma Image
- Ureter, Intraoperative Injury
- Renal Trauma, Adult
- Bladder Injury, Intraoperative
- Ureter, Stricture
- Ureter Trauma Image

**REFERENCES**

**ADDITIONAL READING**

** Hình ảnh**

- Ureter, Intraoperative Injury
- Renal Trauma, Adult
- Bladder Injury, Intraoperative
- Ureter, Stricture
- Ureter Trauma Image

**CODES**

- ICD9: 551.9 Other injury of ureter, without mention of open wound into cavity
- ICD-10: S37.5 Other intraoperative complications of peritoneal system
- S37.59 Other intraoperative complications of genitourinary system
- S37.10XA Unspecified injury of ureter, initial encounter
- S37.19XA Other injury of ureter, initial encounter

**CLINICAL/SURGICAL PEARLS**

- Diagnosis of ureteral injury requires a high index of suspicion.
- Absence of hematuria does not exclude ureteral injury. Hematuria absent in 25–45% of ureteral trauma.
- Ureteral injury is indicated by extravasation of contrast.
- Primary anastomosis and reimplant with psoas hitch are effective methods for repairing ureteral injuries.
- More complicated injuries can be managed in a delayed fashion.
- Unstable patients can be managed with temporary drainage followed by delayed management.
URETEROCELE
Ross M. Decter, MD, FRCS
Paul H. Smith III, MD

BASICS
DESCRIPTION
Ureterocele is a cystic dilation of the terminal/intravesical ureter. May be classified based on anatomic location:
– Intravesical: Contained entirely within the bladder above the bladder neck; seen frequently in single system ureteroceles.
– Extravesical (Ectopic): Some portion of ureterocele permanently located at the level of the bladder neck or urethra; seen frequently in duplex system ureteroceles.

Descriptive classification:
– Cecoureterocele: Ureterocele extends into urethra, but orifice within the bladder
– Sphincteric
– Stenotic
– Sphinctero-stenotic
– Blind
– Nonobstructive

Most ureteroceles are associated with the upper pole of a duplex collecting system and are usually ectopic

Today many ureteroceles are detected during routine prenatal screening ultrasounds

When discovered in adults they are rarely of clinical consequence.

EPIDEMIOLOGY
Incidence
1 in 500 to 1 in 4,000
Prevalence
As high as 1 in 500 (autopsy study)

RISK FACTORS
– More common in girls (5–7:1)
– More common in whites
– Bilateral in 10–15% of cases
– Extravesical ureteroceles associated with upper pole of duplex system often diagnosed in infancy or childhood

Genetics
 Likely multifactorial inheritance

PATHOPHYSIOLOGY
Several hypotheses:
– During embryogenesis, the mesonephric duct and the distal ureteral bud incorporate into the anterior cloaca/urogenital sinus. Chawalla membrane breaks down allowing the incorporation of the distal ureter into the developing bladder. Incomplete breakdown of Chawalla membrane is thought to be one cause of the ureterocele.
– Delay in canalization of ureter-urethral bud is another theory.

ASSOCIATED CONDITIONS
– Duplicated collecting system: 60%
– Single system: 20%
– Most common type in boys, but uncommon in girls (5%)
– Vesicoureteral reflux (VUR) – Ureteral lower pole in duplex system: 50–70% – Contralateral kidney: 10–30%

GENERAL PREVENTION
Antibiotic prophylaxis in patients at risk for upper-tract infection (VUR or obstruction)

DIAGNOSIS
HISTORY
– Prenatal hydronephrosis
– UTI/sepsis/failure to thrive
– Hematuria
– Bladder outlet obstruction
– Bladder outlet obstruction is most common cause of bladder outlet obstruction in newborn girls
– Intravesical mass (ectopic ureterocele)

PHYSICAL EXAM
– Abdominal mass (hydronephrosis)
– Intralabial prolapsing cystic mass
– Smooth, broad- based filling defect near trigone

IMAGING
– Renal/bladder US:
– Prenatal hydronephrosis
– Thin-walled intravesical cystic structure or septations in the bladder
– Hydronephrosis
– Duplex collecting system with dilated upper pole
– Voiding cystourethrogram (VCUG):
– Smooth, broad- based filling defect near trigone
– Critical to image during early filling

DIAGNOSTIC TESTS & INTERPRETATION
Lab
– Serum creatinine
– Urinalysis
– Urine culture

Imaging
– Renal/bladder US:
– Prenatal hydronephrosis
– Thin-walled intravesical cystic structure or septations in the bladder
– Hydronephrosis
– Duplex collecting system with dilated upper pole
– Voiding cystourethrogram (VCUG):
– Smooth, broad- based filling defect near trigone
– Critical to image during early filling

– May efface as bladder fills

DIFFERENTIAL DIAGNOSIS
– Bladder polyp
– Ectopic ureter
– Edema
– Mesonephric duct cyst
– Tumor
– Urethral prolapse

TREATMENT
GENERAL MEASURES
Surgical treatment is needed in most cases

MEDICATION
First Line
– Culture-directed antibiotics for treatment of UTI
– Antimicrobial prophylaxis until reflux or obstruction repaired in children
– Amoxicillin: 5–7 mg/kg as neonate
– Trimethoprim-sulfamethoxazole: 2 mg/kg/d OR nitrofurantoin 1–2 mg/kg/d beyond 2 mo of age

Second Line
Endoscopic incision if acutely septic
URETEROCELE

Surgery/Other Procedures

- Endoscopic transurethral incision:
  - Usually effective in relieving obstruction
  - Risk of developing reflux in that system
  - Outpatient procedure
  - Effective for intravesical and single-system ureteroceles, less so for extravesical ureteroceles (CUB)
  - Can be a temporizing measure until definitive repair (CUB)
- Formal surgical repair:
  - Definitive treatment but higher morbidity
  - Goals of surgery: Preserve functional renal parenchyma, relieve obstruction, correct reflux
  - Upper-pole heminephrectomy if dilated, non-functioning upper pole
  - Ureteroureterostomy if upper pole is functional and no lower pole reflux
  - Ureterocele excision and common sheath reimplantation if reflux is present (CUB)

Additional Treatment

Radiation Therapy
No

Additional Therapies

Observation if asymptomatic; no or mild reflux or obstruction

Complementary & Alternative Therapies
No

Ongoing Care

Prognosis

Depends on extent of obstruction, infections, and presence or absence of renal dysplasia

Complications

- The major complication in adults and children is ureteral obstruction (4)
- Sepsis, loss of renal function
- Incontinence (primary or secondary)
- Persistent dilution of ureteral stump
- Persistent VUR

Follow-Up

- Patient Monitoring:
  - Renal and bladder US
  - VCUG to diagnose/follow-up VUR
  - Monitor renal function if bilateral
  - Treat UTI

Codes

ICD9
- 583.70 Vesicoureteral reflux unspecified or without reflux nephropathy
- 583.89 Other specified disorders of kidney and ureter
- 753.23 Congenital ureterocele

ICD10
- N13.30 Vesicoureteral reflux, unspecified
- N28.89 Other specified disorders of kidney and ureter
- Q62.31 Congenital ureterocele, orthotopic

Clinical/Surgical Pearls

- Early filling x-rays during VCUG mandatory to enhance detection of ureterocele.
- Choice of treatment driven by acuity of illness, degree of obstruction, VUR, and degree of renal dysplasia.
- Definitive endoscopic treatment most successful for single-system ureteroceles.
URETEROENTERIC ANASTOMOTIC STRicture

David F. Penson, MD, MPH
Chad R. Ritch, MD, MBA

DESCRIPTION
Ureteroenteric anastomotic stricture (UE) is typically a benign obstruction of the ureter at the level of the ileal urinary diversion.

- Typically benign process that develops 7–18 mo postoperatively (1)
- Most often performed in setting of radical cystectomy and urinary diversion; therefore, recurrent malignancy must be ruled out (malignant stricture)

PHYSICAL EXAM
- Full acute pain on palpation of flank
- May be sharp if associated with infection

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM
- Complain of flank pain or fever and UTI suggestive of pyelonephritis
- Typically presents 6–18 mo after surgery or chronic as opposed to acute process

IMAGING
- If kidney appears atrophic consider renal scan to assess function
- Ultrasound cost-effective and highly sensitive for obstructive process
- CT imaging with pre- and post-IV contrast dye can provide further anatomic and functional information
- More costly than US and risk of radiation exposure and contrast-dye allergy in susceptible patients
- Patients may have compromised renal function that precludes the use of IV contrast
- Some patients may have compromised renal function if feasible contrast dye allergy in susceptible patients
- Nephrostogram can be therapeutic by providing instant drainage via nephrostomy as well as access to locate and cannulate ureteral orifice during loop enterostomy

DIFFERENTIAL DIAGNOSIS
- Ureteral stone
- Extrinsic compression
- Urinary infection
- Recurrent malignancy
- Pyelonephritis
- Differential can be explored with CT or MR imaging which will provide anatomical detail

TREATMENT
- Consider pain relief if obstruction causing hydronephrosis and flank pain
- Rule out and treat UTI if suspected
- Ureteral stent may prevent urine leak
- Nephrostomy tube and systemic antibiotics
- If patient comfortable and no evidence of infection, then consider elective repair

DIAGNOSIS
- Complain of flank pain or fever and UTI suggestive of pyelonephritis
- Typically presents 6–18 mo after surgery
- Chronic as opposed to acute process

GENERAL MEASURES
- Consider pain relief if obstruction causing hydronephrosis and flank pain
- Rule out and treat UTI if suspected
- Ureteral stent may prevent urine leak
- Nephrostomy tube and systemic antibiotics
- If patient comfortable and no evidence of infection, then consider elective repair

Epidemiology
- Various series report range of 3–10% (1,2)
- More common on left (1,2)

Prevalence
N/A

RISK FACTORS
- Surgical technique is the main risk factor
- Aggressive handling of the ureter leads to stricture formation
- Excessive tension on the ureter
- A non-refluxing anastomosis may be more prone to stricture formation than a refluxing anastomosis
- Suture-line gaps lead to urine leak and predispose to stricture

Genetics
N/A

PATHOPHYSIOLOGY
- Aggressive handling, suboptimal technique devascularizes tissue causing poor blood flow and ischemia
- Ectasia interferes with healing of ureteral tissue and causes stricture formation
- Ureteral stricture formation or leakage causes inflammation around anastomotic site
- Lack of mucosa to mucosa apposition impairs healing

ASSOCIATED CONDITIONS
- Any condition where surgical or injury occurs may result in stricture formation
- Urinary tract infection
- Bladder carcinoma
- Neurogenic bladder
- Gynecologic malignancies
- Pelvic exenteration for malignancy

GENERAL PREVENTION
- Good surgical technique essential
- No grasping of ureter with instruments, may crush and devascularize tissue
- Maintain good blood supply—Avoid skeletonization
- Minimize stretching and tension
- Ensure mucosa to mucosa apposition
- Balance wright Anastomosis with excessively devascularized tissue
- Urinary stent may prevent urine leak

Lab
- CT imaging with pre- and post-IV contrast dye can provide further anatomic and functional information
- More costly than US and risk of radiation exposure and contrast-dye allergy in susceptible patients
- Patients may have compromised renal function that precludes the use of IV contrast
- Some patients may have compromised renal function if feasible contrast dye allergy in susceptible patients
- Nephrostogram can be therapeutic by providing instant drainage via nephrostomy as well as access to locate and cannulate ureteral orifice during loop enterostomy

DIFFERENTIAL DIAGNOSIS
- Ureteral stone
- Extrusive compression
- Urinary infection
- Recurrent malignancy
- Pyelonephritis
- Ureteral kinking
- Recurrent malignancy
- Differential can be explored with CT or MR imaging which will provide anatomical detail
URETEROENTERIC ANASTOMOTIC STRicture

MEDICATION
First Line
- No therapeutic medications
- Consider narcotics and anti-inflammatories for temporary relief of pain
- If infection noted and patient clinically stable, mildly symptomatic, treat with fluoroquinolone or culture specific antibiotics for 7–14 days
- Asymptomatic infection can be treated prior to elective repair

Second Line
- SAH

SURGERY/OThER PROCEDURES
- Nephroureteral or antegrade ureteral stent placement for temporary relief of obstruction or in the setting of palliative care
- Definitive therapy. Open versus endoscopic repair – Decision is based on surgeon experience, prior attempts at repair (primary vs secondary) and length/complexity of stricture
- Retrospective series suggest higher success rates with open repair (see below)
- Indwelling stent for 2–3 wk after repair
- Open surgical repair – Recommended for strictures >1 cm and failed endoscopic repairs
- Success rates of up to 71.4–100% reported for primary open revision (2,3)
- Difficult procedure with mean reported operative time of 240+ (145–450) min, EBL 300+ (150–500) cc (2,4)
- Endoscopic repair – Recommended for stricture <1 cm and primary repairs
- Typically performed antegrade with Ho:Yag laser or Accucise device (2,5). Balloon dilation less commonly used and may be less efficacious
- Success rates of 36–50% reported for primary repair (3–5)
- Secondary or redo endoscopic repair has low success rate (50%) (5)
- Left side strictures and those >1 cm in length appear more prone to failure after repair (2,5)

ADDITIONAL TREATMENT
Radiation Therapy
- N/A

Additional Therapies
- If external stricture very long, ureter deaucesalvored or insufficient length and renal unit still functional consider bowel interposition (tailed ileum)
- If renal scan demonstrates poorly functioning kidney (<15%) consider nephrectomy

Complementary & Alternative Therapies
- N/A

Ongoing care

PROGNOSIS
- Mean time to failure after open and endoscopic repair are 12 and 5 mo, respectively (3)
- Left sided and redo repairs are at higher risk for failure

COMPLICATIONS
- Uretero enteric stricture – Stone formation
- Hydroureter
- Renal insufficiency
- Pyelonephritis
- Open repair: complication rate of up to 40% (2,4)
- Complications include vascular injury, contralateral ureteral injury, urine leak, damage to diversion bowel segment, bowel injury (2,4)
- Endoscopic repair:
  - Complications are rare, most common is infection (UTI)success rate (2,3-5)

FOLLOW-UP
Patient Monitoring
- Consider renal US at 6 weeks following repair
- If hydroureter present consider waiting 2 wk potential post-op anastomotic edema and perform repeat imaging with contrast based study to rule out obstruction/failure
- Reflux may occur following repair so should also rule out as possible cause of hydroureter

Patient Resources
- N/A

REFERENCES

ADDITIONAL READING

See Also (Topic, Algorithm, Media)
- Hydroureter/hydroureteronephrosis, (bladder Ureteral Reflux Disease), Adult
- Ureter, Obstruction

CODES
ICD9
- 593.3 Stricture or kinking of ureter
- 667.2 Injury to ureter, without mention of open wound into cavity
- 997.5 Urinary complications, not elsewhere classified

ICD10
- N13.5 Crossing vessel and stricture of ureter into hypogastric
- N69.89 Other postprocedural complications and disorders of GI sys
- S37.10XA Unspecified injury of ureter, initial encounter

CLINICAL/SURGICAL PEARLS
- Avoid aggressive handling of the ureter to prevent deaucesalvored or ischemia during urinary diversion operation
- If hydronephrosis, fever, and UTI in a patient with a urinary diversion requires emergent treatment with percutaneous drainage
- Open primary repair of UE stricture has higher success rate than endoscopic repair
- Open repair is complex procedure best performed in experienced hands
URETEROPELVIC JUNCTION OBSTRUCTION
Christopher E. Keel, DO
Raju Thomas, MD, MHA, FACS

BASICS
DESCRIPTION
- Ureteropelvic junction obstruction (UPJO) is a restriction of urine flow from the renal pelvis to the ureter.
- Most common cause of significant dilation of collecting system in fetal kidney

EPIDEMIOLOGY
Incidence
- 1: 500–1000 newborns
- 25% diagnosed by 1 yr, 50% by 5 yr
- Adult presentation usually in 10th–40th decade

Prevalence
- Left > right side (6:1)
- Male > female (2:1:1)

RISK FACTORS
- Familial disposition
- Congenital renal anomalies:
  - Contralateral UPJO: 10–40% risk
  - Vescoureteral reflux (VUR): 0.5–5% risk
- Familial disposition
- Male
- Left
- Adult presentation usually in 3rd–4th decade

ASSOCIATED CONDITIONS
- 50% associated with another congenital anomaly:
  - Contralateral renal agenesis or multicystic dysplastic kidney (MCDK)
  - Contralateral UPJO
- Most common:
  - Horsehoe kidney: 15% risk
  - Ectopic kidney: 15% risk

PATHOPHYSIOLOGY
- Congenital (most common etiology):
  - Adynamic ureteral segment due to ureteral smooth muscle maldevelopment: the most common cause of pediatric UPJO
  - Trabeculation: due to inadequate ureteral recanalization during fetal development
  - Persistent valvular mucosal folds
  - Ectopic ureter:
  - Crossing accessory lower pole vessel: most common cause of adult UPJO
  - High ureteral insertion into renal pelvis
  - Horsehoe kidney, ectopic, or malpositioned kidney causing kinking at ureteropelvic junction (UPJ)

- Acquired:
  - Severe VUR can cause ureteral tortuosity and kinking at UPJ
  - Inflammation and scarring from trauma, ureterolithiasis, instrumentation, infected urine, or perirenal fibrosis

ASSOCIATED CONDITIONS
- 50% associated with another congenital anomaly:
  - Contralateral renal agenesis or multicystic dysplastic kidney (MCDK)
  - Contralateral UPJO
- Most common:
  - Horsehoe kidney: 15% risk
  - Ectopic kidney: 15% risk
- Incomplete renal duplication
- Unilateral renal agenesis
- VACTERL/VACTERL syndrome
- VUR

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Prenatal/infant presentation:
  - Hydronephrosis seen on antenatal US
  - Typically asymptomatic but occasionally sees feeding difficulties, failure to thrive, sepsis
- Childhood presentation:
  - Episodic abdominal complaints or bilateral colicky flank pain
  - Cyclical nausea and vomiting
  - Gross hematuria, classically after minor abdominal or flank trauma
- Adult presentation:
  - Episodic (isolated) colicky flank pain, classically after dextrin or alcohol intake (aka Diet crisis)
  - Cyclical nausea and vomiting
  - UTI or pyelonephritis

PHYSICAL EXAM
- Prenatal/infant presentation:
  - Painless abdominal mass
  - Fever (in neonates)
- Childhood presentation:
  - Costovertebral (CVA) tenderness
  - Palpable abdominal mass
  - Feeding difficulties, failure to thrive
- Adult presentation:
  - CVA tenderness
  - Hypertension (HTN) due to acute pain or activation of renin–angiotensin–aldosterone system

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum BUN and creatinine
- Urine analysis:
  - Microscopic hematuria, rarely gross
  - Trace proteinuria
  - Pyuria and bacteriuria
- Urine culture

Imaging
- Renal US:
  - Most often used as initial screening study in pediatric population
  - Useful to distinguish renal masses and ureteropelvic junction obstruction from UPJO
- Delay until 2nd or 3rd day of life to avoid false-negative result secondary to physiologic oliguria
- Renal ultrasound
  - Cystoscopy with retrograde pyelography:
  - Allows visualization of collecting system and renal vasculature (crossing vessels)
  - Peritoneal catheter with pressure transducer
    - Defined as > 20 cm/H2O
    - Allows for placement of temporary ureteral stent to relieve ureteral obstruction
  - Magnetic resonance urography (MRU)
    - Allows for recanalization during fetal development
  - Intravenous pyelogram (IVP)
    - Most often used as initial screening study in pediatric population

DIFFERENTIAL DIAGNOSIS
- Obstructive dilation:
  - Fecal balls
  - Impacted ureteral calculus
  - Intrarenal-bowel or malignant neoplasm
  - Sloughed papilla
- Nonobstructive dilation:
  - Perinephric and periureteral fluid:
  - VUR
  - Megacyste

TREATMENT
GENERAL MEASURES
- Prevent further deterioration in renal function
- Relieve symptoms of obstruction

MEDICATION
First Line
- Neointestinal stent placement:
  - Prophylactic antibiotics to maintain sterile urine
  - UPI prophylaxis: amoxicillin 25 mg/kg/d as neonates THEN
  - Trimethoprin-sulfamethoxazole 2 mg/kg/d OR nitrofurantoin 1–2 mg/kg/d beyond 2 mo of age
  - Repeat imaging—to monitor for resolution or deterioration of function (1)
- Childhood and adult presentation:
  - No medical therapy appropriate except to treat active infection

Diagnostic Procedures/Surgery
- Cystoscopy with retrograde pyelography:
  - Allows visualization of collecting system and renal vasculature (crossing vessels)
- Magnetic resonance imaging (MRI): 3D reconstruction:
  - Allows visualization of collecting system and renal vasculature (crossing vessels)
- Helical CT scan with 3D reconstruction:
  - Allows visualization of collecting system and renal vasculature (crossing vessels)
- Peritoneal catheter with pressure transducer
  - Defined as > 20 cm/H2O
- Bilateral UPJ obstruction
  - Residual urine: 22 cm/H2O
  - Obstructed: > 20 cm/H2O
URETEROPELVIC JUNCTION OBSTRUCTION

SUGERY/OHER PROCEDURES

- **Purpose:** Restore renal function
- **Definitive operative treatment:**
  - Expectant management in the neonate:
  - Treat pyonephrosis if present:
- **Purpose:** Restore renal function

- **Laparoscopic pyeloplasty:** Success rate ~ 95%; appropriate for adults with stricture < 2 cm, UPJO associated with renal calculus, children with secondary UPJO
- **Robotic assisted laparoscopic pyeloplasty:**
  - Employ dismembered or Y-V plasty technique;
  - Offers decreased morbidity, better cosmesis, and ease in surgical dissection and suturing
  - Gaining more acceptance and is now becoming the standard approach, even in the pediatric population, with increasing access to robotic surgical technology (3).
- **Ureterocalycostomy:**
- **Spiral or vertical flap:** Appropriate for large narrowed ureter
- **Foley Y-V plasty:** Appropriate for high ureteral involvement; excise anatomic and functional abnormal segments
- **Open pyeloplasty:** Procedure of choice in pediatric patients
- **Dismembered (Anderson-Hynes) pyeloplasty:**
  - Most common open technique; success rate ~ 95%
  - Indicated for high insertion, accessory vessels, massive dilatation, long-segment involvement; excise anatomic and functionally abnormal segments
- **Pediatric Y-V plasty:** Preferred for high insertion
- **Ureteric flap technique:** Appropriate for large extrarenal pelvis and long segment of narrowed ureter
- **Ureteroureterostomy:** Appropriate for rotational anomalies or reoperation after failed pyeloplasty; partial lower pole nephrectomy is required to prevent anastomotic stenosis
- **Simple nephrectomy:** May be appropriate for unilateral poor renal function and normal contralateral renal function, especially if differential renal function < 10–15%, extensive stone disease, chronic infection, multiple failed repairs

- **Endoscopic procedures:**
  - **Minimal invasive alternative to open procedures:** in adults (5)
  - Antegrade cold-knife incision endopyelotomy: Success rate ~ 90%; requires percutaneous access, nephrostomy tube left indwelling 24–48 hr; ureteral stent left indwelling 4–6 wk; appropriate for adult patients with stricture < 2 cm, UPJO associated with renal calculus, children with secondary UPJO
  - Retrograde ureteroscopic beam incision: Success rate 90–95%, allows direct visualization of incision; required specialized ureteroscopic equipment and endourologic expertise
  - Ureteroceles: reserved for patients who are not candidates for definitive operative treatment

ONGOING CARE

- **Frequent visits**
- **Bilateral nephrectomy:** May be appropriate for the management of patients who have undergone failed pyeloplasty
- **Ureteroureterostomy:**
- **Urinary tract infection:**
- **Rarely nephrectomy**

FOLLOW-UP

- **Patient Monitoring:**
  - **Urine analysis:**
  - **Renal US or MAG3 6–12 wk postop**
  - **Antegrade cold-knife endopyelotomy:**
  - **Retrograde ureteroscopic beam incision:**
  - **Endoscopic procedures:**

COMPLICATIONS

- **Renal structure:**
  - **Ureteroureterostomy:**
  - **Ureteroneocystostomy:**
  - **Renal infection:**
- **Rarely nephrectomy**

PEARLS

- **RECOMMENDATION:**
  - **Ureterocalycostomy:**
  - **Open pyeloplasty:**
  - **Laparoscopic pyeloplasty:**
  - **Robotic assisted laparoscopic pyeloplasty:**

CLINICAL/SURGICAL PEARLS

- **Purpose:** To relieve obstruction and preserve kidney function
- **Open or laparoscopic surgical repair remains the best option for treatment.**
URETHRA, ABSCESS (PERIURETHRAL ABSCESS)

H. Henry Lai, MD, FACS
Gerald L. Andriole, MD, FACS

ASSOCIATED CONDITIONS (2)
- Diabetes mellitus
- Immunosuppression (eg, HIV)
- Sexually transmitted disease
- Urinary tract infection

GENERAL PREVENTION
- Excise and prevent sexually transmitted disease
- Sterilize the urine and defer instrumentation if the urine is infected
- Division of urine away from the urethra
- Adequate management of urethral stricture: – Dilatation
- – Interventional urotherapy
- – Urethroplasty and reconstruction
- – Perineal urotherapy

DIAGNOSIS

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM
- Evaluate for septic shock
- Look for extravasation, stricture, fistula
- Not recommended during acute phase

DIAGNOSTIC PROCEDURES/SURGERY
- – Look for extravasation, stricture, fistula
- – Transrectal ultrasound imaging of prostate: not recommended during acute phase

PATHOPHYSIOLOGY
- Perineal extravasation of infected urine
- Ureteral extravasation may be caused by:
- High-pressure voiding behind a stricture
- Difficult dilatation of a stricture, false passage
- Traumatic urethral instrumentation
- Often localized to the bulbar urethra or spongiosum
- Once eroded through Buck’s fascia, may cause extensive necrosis of the fascia and adjacent tissues, leading to Fournier gangrene.
- Three potential sources of Fournier gangrene: – Perineal
- – Perirectal
- – Subcutaneous
- Fistula may develop in delayed cases following spontaneous abscesses rupture
- Common organisms: – Aerobic gram negative
- – Anaerobic gram negative
- – Enterococci
- – Anaerobes

HISTORY
- Symptoms may include urethral discharge, dysuria, pain, swelling of penis or scrotum, foul-smelling urine, fever, chills, weak urine stream, incomplete emptying, urinary frequency, urgency
- History of urethral stricture and treatment
- Recent history of urethral instrumentation, dilatation, catheterization, bulking agent, sling, or other surgery
- History of sexually transmitted disease, pelvic radiation, trauma (risk factors of stricture)
- History of recurrent UTI
- Diabetes, including glomerular control
- Immunosuppression (eg, HIV)
- Prior periurethral abscesses and treatment
- Maintain an index of suspicion for neoplasm for recurrent periurethral abscesses and stricture

DIAGNOSIS

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM
- Evaluate for septic shock
- Look for extravasation, stricture, fistula
- Not recommended during acute phase

DIAGNOSTIC PROCEDURES/SURGERY
- – Look for extravasation, stricture, fistula

- – Perirectal
- – Subcutaneous
- Fistula may develop in delayed cases following spontaneous abscesses rupture
- Common organisms: – Aerobic gram negative
- – Anaerobic gram negative
- – Enterococci
- – Anaerobes
TREATMENT

GENERAL MEASURES
Supportive treatment of other medical issues (diabetes, hypotension, septic shock, or organ failures).

MEDICATION

First Line
- Broad-spectrum antibiotics coverage
  - Ceftriaxone 2g IV q24 + gentamicin 1.5–2 mg/kg loading dose, followed by 5–7 mg/kg IV q24
  - Consider vancomycin (15–20 mg/kg IV q12)

Second Line
- Antibiotics are adjusted based on culture sensitivity

SURGERY/OTHER PROCEDURES
- Incision and drainage of abscess with debridement and excision of necrotic tissue
- May require repeated exploration and debridement as the margin between necrotic tissue and viable tissue becomes more apparent
- Needle aspiration or endoscopic transurethral incision may be considered in selected cases
- Wet to dry dressing change twice a day
- Exposed testicle may be placed in the scrotum or thigh pouch
- Wound vac placement after debridement if the wound is clean and if wound location permits
- Needle aspiration or endoscopic transurethral incision may be considered in selected cases
- Incision and drainage of abscess with debridement and excision of necrotic tissue
- Board spectrum antibiotics coverage
- Supportive treatment of other medical issues:
  - General measures
  - Testing for sexually transmitted disease
  - Periodic evaluation of urine for infection
  - Monitoring for recurrent stricture (eg, uroflow)
  - Frequent wound check until healed

FOLLOW-UP

Patient Monitoring
- Frequent wound check until healed
- Monitoring for recurrent stricture (eg, uroflow)
- Periodic evaluation of urine for infection
- Testing for sexually transmitted disease

Patient Resources
- Urology Care Foundation: Benign urethral lesions Patient Monitoring
- Urology Care Foundation: Urinary incontinence
- Urology Care Foundation: Benign prostatic hypertrophy
- Urology Care Foundation: Urinary tract infection
- Urology Care Foundation: Urethral diverticulum

URINARY DIVERSTION
- Urinary diversion with suprapubic tube are important in the treatment of urethral abscess
- Urinary diversion with suprapubic tube are important in the treatment of urethral abscess
- Urinary diversion with suprapubic tube are important in the treatment of urethral abscess
- Urinary diversion with suprapubic tube are important in the treatment of urethral abscess

ADDITIONAL READING

CLINICAL/SURGICAL PEARLS

- In men, urethral abscess is associated with urinary infection, urethral stricture, diabetes, and immunosuppression. In women, it is associated with urethral diverticulum.
- Incision and drainage of abscesses may include exploration and debridement of necrotic tissues.
- Board spectrum antibiotics coverage and supportive care.
- Urinary diversion with suprapubic tube are important in the treatment of urethral abscess.
- Early recognition and treatment is key to prevent progression to life-threatening Fournier gangrene and septic shock.
URETHRAL CARCINOMA, GENERAL CONSIDERATIONS

Michael A. Poch, MD
Philippe E. Spiess, MD

BASICS

DESCRIPTION
• Urethral carcinoma is a tumor arising from the lining of the male or female urethra
• Considered a rare cancer (<1 of all malignancies)
• Urethral carcinoma is most common histologic type followed by squamous cell carcinoma and adenocarcinoma.

EPIDEMIOLOGY (1)

Incidence
• Incidence (male): 1.6 per 1,000,000
• Incidence (female): 0.6 per 1,000,000

RISK FACTORS (1)

- Incidence increases steadily with age, more steeply in men as compared to women peaks at age 75:
- 7,811,000,000

Prevalence

N/A

DIAGNOSIS

HISTORY
• Urethral bleeding
• Perineal discomfort
• Decrease force of stream
• Urinary frequency
• Urinary urgency
• Dysuria
• Urinary fistula
• Urinary tract infection

PHYSICAL EXAM
• Perineal exam
  - Identifies palpable mass in proximal urethra
  - Pelvic exam
    - Identifies visual or palpable mass associated with female urethra
    - Examination under anesthesia with bimanual exam
    - Inguinal exam to evaluate palpable inguinal adenopathy

Diagnostic Procedures/Surgery

Cylcoplasty with brachytherapy/external beam

Pathologic Findings (2)

- Urethral carcinoma 30-40%
- Squamous cell carcinoma 16-25%
- Adenocarcinoma 10-16%
- More common in women, traditionally considered more prevalent

ASSOCIATED CONDITIONS

- HPV, condyloma
- External beam or seed implant
- CT thorax and abdomen in patients with invasive disease (rule out metastasis)
- CT scan of pelvis
- C7 scan of pelvis
- CT those and abdomen in patients with invasive disease (rule out metastasis)

Lab

- Urinalysis
- Urine culture
- Urine cytology
  - Sensitivity 55-59%

Imaging

- Urography—Arduous in the diagnosis of diverticula and/or stricture disease
  - Water-soluble contrast (WSS) or IVU
  - Retrograde urethrogram
  - Cross sectional imaging identifies local extension
    - MRI or CT
  - Preferred imaging modality for urethral carcinoma
- C7 scan of pelvis
- CT those and abdomen in patients with invasive disease (rule out metastasis)

- Indwelling catheter
- Urethroplasty
- Interstitial therapy
- External beam or seed implant

Primary tumor staging based on TNM classification
- T—Primary tumor
  - T0—Primary tumor cannot be assessed
  - T1—Primary tumor (less than or equal to T1a)
  - T2—Primary tumor extends to surrounding structures
  - T3—Primary tumor extends to surrounding structures beyond prostate capsule
  - T4—Primary tumor invades the pelvic cavity

- N—Regional lymph nodes
  - N0—No regional lymph node metastases
  - N1—Metastasis in a single lymph node 2 cm or less
  - N2—Metastasis in a single lymph node > 2 cm or multiple nodes

- M—Distant metastasis
  - M0—No distant metastasis
  - M1—Distant metastasis

- Primary tumor in prostatic urethra
  - Ta—Non-invasive papillary carcinoma
  - T1—Carcinoma in situ
  - T2—Carcinoma in situ invading the prostatic ducts
  - T3—Carcinoma in situ invading the prostatic capsule
  - T4—Carcinoma in situ invading beyond the prostatic capsule

- Adequate lymphadenectomy
- Neoadjuvant therapy
- Radical or partial urethral resection

- Adjuvant therapy
- Radiation therapy
- Hormonal therapy
- Surgical salvage

PREVENTION

- Prevention of traumatic injury leading to stricture disease
  - Indwelling catheter
  - Urethroplasty

- Indwelling catheter
- Urinary fistulae
- Dysuria
- Urinary urgency
- Perineal discomfort
- Urethral bleeding

- History of sexually transmitted infection (STI/STD)
- Chronic inflammation
- Adenocarcinoma of bulbar urethra
- Prior radiation

- Urethral stricture disease
- Urethritis
- History of sexually transmitted infection (STI/STD)
- Chronic inflammation

- Adenocarcinoma: Occurs in urethra diverticula
- Squamous-cell carcinoma: Occurs at distal 2/3 of the urethra
- Adenocarcinoma: Occurs in the proximal 1/3 of the urethra
URETHRAL CARCINOMA, GENERAL CONSIDERATIONS

DIFFERENTIAL DIAGNOSIS
- Adenocarcinoma
- Squamous papilloma
- Transitional cell papilloma
- Lymphoma
- Naphrogenic adenoma
- Ameloblastoma
- Urethral cancer
- Leukoplakia
- Vesical ulcer
- Skin gland, inflammation/adenitis
- Urethral diverticulum
- Urethral fistula
- Urethral stricture
- Malignant neoplasms
  - Adenocarcinoma
  - Melanoma
  - Metastatic disease
  - Skene (paraurethral gland) adenocarcinoma
  - Squamous cell carcinoma
  - Urethral carcinoma

TREATMENT
GENERAL MEASURES (1,3)
Based on pathology, stage, location of tumor

MEDICATION
First Line
- No medical therapy as first-line treatment
- Preoperative cisplatin-based systemic chemotherapy followed by surgery for locally advanced urothelial cancer has demonstrated a survival advantage
- Preoperative chemoradiation followed by surgery for locally advanced squamous cell carcinoma has demonstrated a survival advantage

Second Line
- Adjusted systemic chemotherapy based on underlying tumor histopathology

SURGERY/OTHER PROCEDURES
- Male
  - Perineal urethra
    - Transurethral resection (TUR)
  - Proximal penile urethra—total penectomy
  - Prostatic urethra
  - TUR + BCG for Ta or Tis
  - Higher stage radical cystoprostatectomy
  - Bulking materials
  - TUR
  - Primary excision with primary anastomosis
  - Cystoprostatectomy with urethroctomy and total penectomy, with possible pelvic lymph node dissection
  - Locally advanced disease. Excision of pubic rami
- Female
  - Distal
  - Partial urethrectomy or TUR
  - Prostate—often presents at higher stage
  - Anterior pelvic exenteration
  - Pelvic lymph node dissection

ADDITIONAL TREATMENT
Radiation Therapy
- Used as primary therapy for low-stage distal urethral carcinoma in females
- Primary brachytherapy or external beam
- Used as adjuvant therapy for advanced cancer

Additional Therapies
- Neoadjuvant chemotherapy only recommended for palpable disease or for high-risk disease in the distal urethra

Complementary & Alternative Therapies
- None

ONGOING CARE
PROGNOSIS (4)
- Male
  - 5-yr survival: Depends on location, stage, and pathology
- Female
  - 5-yr survival: Depends on location, stage, and pathology
- Complications
  - Associated surgical complications
  - Abcess
  - Cystitis
  - Incontinence
  - Stricture
  - Fistula

FOLLOW-UP
Patient Monitoring
- O3–4 mo cystoscopy and urine cytology
- Cross-sectional imaging to evaluate for local recurrence
- Recurrences often occur early (1–2 yr)

Patient Resources

REFERENCES

ADDITIONAL READING

CODES
- ICD9
  - 189.3 Malignant neoplasm of urethra
  - 597.80 Urethritis, unspecified
  - 599.0 Urethral stricture, unspecified

- ICD10
  - C68.0 Malignant neoplasm of urethra
  - N35.9 Urethral stricture, unspecified
  - N34.2 Other urethritis
  - N35.9 Urethral stricture, unspecified

CLINICAL/SURGICAL PEARLS
- Urethral cancers appear to be associated with infection with human papillomavirus (HPV), particularly HPV16, a strain of HPV known to be causative for cervical cancer.
- Most urethral cancers are managed surgically.
- Low-grade female distal urethral cancer can be managed with radiotherapy.
- Most locally advanced urethral tumors are best approached by neoadjuvant systemic chemotherapy (i.e., radiotherapy) followed by consolidative surgical resection.
- Outcome strongly correlates with stage.
URETHRAL CARUNCLE
Margarita M. Aponte, MD
Victor W. Nitti, MD, FACS

BASICS
DESCRIPTION
Urethral caruncle is a benign tumor consisting of friable mucosa at the posterior edge of the urethral meatus in females.
• Most are asymptomatic.
• Most common in postmenopausal females.

EPIDEMIOLOGY
Incidence
• Most common benign tumor of the female urethra.
• Occurs more frequently in postmenopausal women.
• Uncommon in childbearing years.
• Extremely rare in children.

Prevalence
Common in postmenopausal elderly women.

RISK FACTORS
• Postmenopausal vaginal atrophy
• Chronic irritation to the urethral meatus

Genetics
No known genetic association

PATHOPHYSIOLOGY
• Mucosal ectropion of posterior urethral wall secondary to retraction of an atrophic vagina due to decreased estrogens
• Appears unrelated to any viral etiology
• Some cases may be related to the autoimmune phenomena of IgG4-associated disease

ASSOCIATED CONDITIONS
Vaginal atrophy

GENERAL PREVENTION
Prevention of vaginal atrophy

DIAGNOSIS
HISTORY
• Determine menopausal status, as more common in postmenopausal females
• Incidental finding on pelvic exam in asymptomatic women
• Light bleeding or spotting on underwear
• Micropapillary hematuria
• Vaginal irritation
• Occasional dyspareunia
• Voiding or obstructive symptoms infrequent
• Tenderness is infrequent

PHYSICAL EXAM
• Erythematous, soft, friable mass seen protruding from a segment of the urethral meatus and palpated on vaginal inspection
• Usually reddish, occasionally may appear blue or black
• Usually located at the ventral (posterior) urethral meatus
• May be tender to palpation
• Usually < 1–2 cm

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• There are no diagnostic lab tests
• Urine analysis may show RBCs or epithelial cells
• Urine cytology may identify malignancy but it is unrelated to the urethral caruncle

Imaging
• Urethroscopy: May help delineate extent of lesion and may be performed in the work up of microscopic hematuria
• Biopsy: Excisional or incisional
– Not usually required for diagnosis, but indicated if mass is suspicious for malignancy, it increases in size or fails to respond to topical estrogen cream.

Pathologic Findings
• Papillomatous, granulomatous, and angiomatous varieties
• Histologic:
– Connective tissue containing many inflammatory cells and blood vessels and covered by an epithelial layer
– Evidence of neovascularization, inflammation, and hemorrhage may be present.
• Transitional or stratified squamous epithelium
• 2% of caruncles have associated malignancy
• Case reports of intestinal heterotopia (1)

DIFFERENTIAL DIAGNOSIS
• Urethral prolapse:
– Eversion of urethral mucosa
– Typically circumferential
– Seen in women of all ages (pubertal through postmenopausal), caruncle is almost exclusively seen in post-menopausal females
• Malignancy:
– Urethral carcinoma:
– Uncommon
– Peak incidence 5th–7th decade
– Usually a firm, nontender, indurated mass
– Irritative and obstructive voiding symptoms may be associated
– Bleeding from urethra or on toilet tissue is more typical.
– Four subtypes of urethral carcinoma: Squamous cell, transitional cell, adenocarcinoma, melanoma (2B).
– Lymphoma
– Intestinal metaplasia
– Periurethral glands abscesses
• Urethral polyp: Pediatric equivalent of urethral caruncle
• Urethral syndrome
• Urethral condyloma
• Urethral varicosities
• Thrombosis of urethral vein:
– Bluish, swollen, very tender lesion in similar location to caruncle
• Other causes of postmenopausal bleeding: Cervical, ovarian, uterine pathology

TREATMENT
GENERAL MEASURES
• Most urethral caruncles are asymptomatic and do not require definitive treatment.
• Conservative management with sitz baths, topical estrogen creams, topical anti-inflammatory agents should be used in the majority of patients.
• Excessive or persistent bleeding of obstructive voiding symptoms may prompt treatment.
• If there is any doubt concerning the diagnosis, biopsy should be performed.
URETHRAL CARUNCLE

MEDICATION
First Line
- Topical estrogen: Apply cream 0.3 mg daily for 2 weeks, then decrease to twice a week for maintenance.
  - Due to minimal absorption, progesterone is not usually needed.
- Anti-inflammatory medications for mild discomfort, PO, or topical.

Second Line
Systemic estrogen replacement

SURGERY/OTHER PROCEDURES
- Excision:
  - Outpatient procedure performed under local anesthesia with or without sedation
  - Remove the entire caruncle and approximate the ventral urethral meatal mucosa to the vaginal epithelium
- Ligation (3)
  - Outpatient procedure performed under local anesthesia
- Cryoablation
- Laser fulguration

ADDITIONAL TREATMENT
- Radiation Therapy
  - Applicable only for certain distal urethral malignancies
  - Not for urethral caruncle
- Additional Therapies
  - Sitz baths may alleviate discomfort.
- Complementary & Alternative Therapies
  - None

ONGOING CARE
- Excellent

COMPLICATIONS
- Urethral stricture or meatal stenosis with surgical excision

FOLLOW-UP
- Patient Monitoring
  - None specific
  - Routine gynecologic follow-up as this is a benign lesion

Patient Resources

PROGNOSIS
- Excellent

ADDITIONAL READING

REFERENCES

CODES
- ICD9
  - 599.3 Urethral caruncle
  - 627.3 Postmenopausal atrophic vaginitis
  - V49.81 Asymptomatic postmenopausal status (age-related) (natural)
- ICD10
  - N36.2 Urethral caruncle
  - N95.2 Postmenopausal atrophic vaginitis
  - Z78.0 Asymptomatic menopausal state

CLINICAL/SURGICAL PEARLS
- Urethral caruncles occur most frequently in postmenopausal women.
- Most are asymptomatic and do not need treatment.
- Biopsy is indicated if there is a suspicion for malignancy.
- Topical estrogen is the first-line treatment.
- Surgical intervention should be reserved for patients with large symptomatic lesions or who fail conservative therapy.
URETHRAL DISCHARGE
Ryan Cleary, MD
Leonard G. Gomella, MD, FACS

ASSOCIATED CONDITIONS
With STI infection common (e.g., gonorrhea and chlamydia)

GENERAL PREVENTION
- Abstinence
- Female and male condoms
- Education and awareness of risky behavior

DIAGNOSIS
History
- Age, sex, and duration
- Roles are more likely to have discharge from a venereal cause
- STIs are most common in the 15–24-yr-old age group
- Venereal or traumatic cause is more likely to have acute onset while chronic inflammation or tumor is usually insidious

- Obtain thorough sexual history to discover risk of STI/STD
- See with men, women, or both
- Oral, vaginal, or anorectal intercourse
- History of STI/STD
- Condyloma
- Ask the time since onset, any inciting events, quality or character, quantity, prior treatments, associated symptoms
- History of irritative or obstructive voiding symptoms
- Hematuria, dysuria, frequency, urgency, incontinence, pollakiuria, dribbling, straining, incomplete emptying
- Hematuria noted at beginning, middle or total voiding course to urethra, bladder or upper tracts, or prostate
- Frequency and urgency can indicate an acute inflammatory response
- Incontinence can indicate a diverticula source
- Straining and incomplete emptying indicate obstructive cause
- History of penile, scrotal, or perineal pain
- Assist in localizing source of discharge
- Any vaginal symptoms
- Vaginal, vulvar, or anorectal symptoms

Lab
- Positive leukocyte esterase on first voided urine is diagnostic of urethritis.

Imaging
- If the cause of the discharge is unclear additional imaging
- Men
- Scrotal ultrasound
- Renal/bladder ultrasound
- CT abdomen and/or pelvis
- MRI pelvis
- Women
- Pelvic ultrasound (transabdominal or transvaginal)
- Renal/bladder ultrasound
- CT abdomen and/or pelvis
- MRI pelvis

PHYSICAL EXAM
- Men
- Request the patient avoid urination before being examined.
- Genital skin exam to evaluate for evidence of trauma, ulcers, rashes, abrasions, or masses
- If no discharge is seen, the urethra should be gently massaged from the ventral part of the penis toward the meatus.
- Examination of testicles and spermatic cord, scrotum, and inguinal lymph nodes
- Women
- Genital skin exam to evaluate for evidence of trauma, ulcers, rashes, abrasions, masses, or masses
- External genitaiia inspection
- Palpation of urethra for mass, fluctuance, or discharge
- Bimanual exam to evaluate for tenderness, mobility, and masses
Diagnostic Procedures/Surgery
- Cystourethroscopy
- Generally needed for more apical presentations and if discharge persists in spite of adequate medical therapy
- Evaluate for mass, erythema, false passage, stricture, or diverticulum of urethra
- Inspect prostate for friability, vascularity, hypertrophy, narrowing, and areas of visual fluctuation

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Inflammatory causes
- Gonococcal urethritis
- Non-gonococcal urethritis
- Chlamydial urethritis
- Mycobacterial genitourinary tract
- Trichomonal vaginitis
- Ureaplasma urealyticum
- Urethral diverticulum
- Urethral tuberculosis
- Trichomoniasis
- TB
- Periurethral abscess
- Reactive arthritis (Previously called Reiter syndrome)
- Masses
- Urethral tumor
- Urethral caruncle
- Urethral hemangioma
- Urethral condyloma
- Urethral caruncle
- Urethral tumor
- Urinary tract system
- Local invasion or metastasis of malignant lesion
- Systemic infection
- Abscess formation in urethra, prostate, epididymis, or testicle
- Local spread to other genitourinary organs – cystitis, prostatitis, epididymitis, orchitis
- Abscess formation in urethra, prostate, epididymis, or testicle
- Systemic infection
- Local invasion or metastasis of malignant lesion
- Recurrent pain

TREATMENT
GENERAL MEASURES
Cause of discharge dictates treatment

MEDICATION
First Line
- Gonococcal and non-gonococcal urethritis
  - Azithromycin 1 g PO x 1 or doxycycline 100 mg PO BID x 7 days plus ceftriaxone 125 mg IM x 1 or cefixime 400 mg PO x 1 as first-line empiric therapy
- Trichomonal
  - Metronidazole 2 g PO x 1 or 250 mg TID x 7 days
- Reactive arthritis
  - N / A
  - Ibuprofen, naproxen, cyclosporine, and sometimes corticosteroids
- BPH
  - See 5α-reductase inhibitors can be used for refractory prostatic bleeding

Second Line
- See 5α-reductase inhibitors can be used for refractory prostatic bleeding

  - Urethritis, Gonococcal and Non-gonococcal

REFERENCES
URETHRAL DIVERTICULA, FEMALE
Alana M. Murphy, MD

BASICS

DESCRIPTION
- A urethral diverticulum is an out-pouching off the urethra between the submucosal layer and the periurethral fascia
- Often contains a collection of urine and/or pus
- Usually connects to the urethra through a neck or ostium
- Classic symptoms are dysuria, dyspareunia, and post void dribbling

EPIDEMIOLOGY

Incidence (1)
- Diagnosis depends on history with which it is sought
- Mean age at surgery: 48 yr

Prevalence
- Difficult to determine true prevalence
- 1-3% asymptomatic women

ASSOCIATED CONDITIONS

Genetics
- No known genetic risk factors

PATOPHYSIOLOGY

- Congenital female urethral diverticula are uncommon
- Most common theory regarding adult female diverticula (2)
  - Infection or obstruction of periurethral glands
  - Obstruction or abscess formation leads to cyst-like cavity
- Diverticulum is contained within periurethral fascia

ASSOCIATED CONDITIONS

- Urinary incontinence
- Dyspareunia
- Dysuria
- Storage or voiding symptoms
  - Occasional urinary retention

GENERAL PREVENTION

No known method of prevention

DIAGNOSIS

HISTORY
- Classic: 3 D's (see table for all to be present):
  - Dysuria: Pain during voiding
  - Urinary (in)convenience: Typically due to urine leaking from the diverticulum, patient may also have concurrent stress and/or urgency incontinence
  - Dyspareunia: Pain with intercourse
- Non-specific complaints are common:
  - Frequency/urgency
  - Hematuria
  - Palpable or visible vaginal lump/lump
  - Perineal pain
  - Recurrent UTIs
  - Voiding symptoms or urinary retention
- May be an incidental finding

PHYSICAL EXAM
- Inspect the anterior vaginal wall:
  - Some diverticula are visible as a suburethral mass
  - Assess bladder neck mobility
  - Observe for stress incontinence
  - Assess for point tenderness suburethraly, which may be the only sign of a vesical diverticulum.
- If a suburethral mass is noted:
  - Classic sign: Compressing the mass expresses urine or pus from urethral meatus.
  - If the mass does not compress:
    - Vaginal wall cyst
    - Obstructed (noncommunicating) diverticulum
    - Induration suggests stone or cancer
  - Evaluate for other pelvic pathology

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Urine analysis, urine culture
- Preoperative tests appropriate to patient’s age and medical condition

Imaging
- Magnetic resonance imaging (MRI)
  - Diverticulum has high signal intensity on T2-weighted imaging
  - Most accurate diagnostic test
  - Does not require the patient to void
  - Helpful in decision-making
  - Not mandatory in straightforward cases
  - Main value: Rule out other pathology
  - Shows size, extent, location, and presence of filling defects
  - Voiding cystourethrogram (VCUG): (3)
    - Advantage: Less anatomic detail
    - Less sensitive for diagnosis
    - Patient must be able to void
  - Fluoroscopic UDS: Combines VCUG with urodynamic assessment of other causes of voiding symptoms
    - Useful if the patient has incontinence or voiding difficulty
    - Not mandatory in straightforward cases
    - Useful if the patient has recurrence or voiding difficulty

DIFFERENTIAL DIAGNOSIS

Benign neoplasms:
- Primary urethral carcinoma; more common in females:
  - Squamous cell (80%)
  - Transitional cell (15%)
  - Adenocarcinoma (4%)
  - Melanoma (1%)
  - Rarely and adenocarcinoma can arise as a urethral diverticulum or in Skene gland

TREATMENT

GENERAL MEASURES
- No treatment is necessary if the patient is asymptomatic
- Patient must understand the small risk that the diverticulum may harbor neoplastic cells
- Little is known about the natural history of untreated diverticula
- Antibiotics and analgesics may control symptoms
- With significant symptomatology, surgical excision is recommended

MEDICATION

First Line
- Antibiotics (eg, trimethoprim/sulfamethoxazole)
- Analgesics (eg, ibuprofen), and antispasmodics (eg, oxybutynin) may control mild symptoms

Second Line
- If first-line medications do not alleviate symptoms, then surgical excision is appropriate

Pathologic Findings

- Histology of epithelium may be:
  - Transitional
  - Stratified squamous
  - Cuboidal
  - Simple (i.e., flat epithelium)
  - May have carcinoma (4)
- Adenocarcinoma more common than transitional or squamous cell
- Diverticulum may contain stones

566
URETHRAL DIVERTICULA, FEMALE

SURGERY/OTHER PROCEDURES
- Transvaginal excision and reconstruction is the most common operation.
- Key principles of excision include:
  - Well-vascularized anterior vaginal wall flap
  - Preserve periurethral fascia
  - Excise diverticulum completely
  - Watertight, tension-free urethral closure
  - Avoid overlapping suture lines
  - Close dead space
  - Multiple layer closure (consider Martius flap)
  - Avoid overlapping suture lines
  - Close dead space
  - Multiple layer closure (consider Martius flap)
  - Adequate bladder drainage with a urethral catheter ± suprapubic catheter
  - Antimuscarinics can be used to prevent bladder spasms

Perform simultaneous anti-incontinence procedure (fascial sling) for stress urinary incontinence (SUI) if:
- Stress incontinence is present before surgery
- Patient desires concomitant treatment

ADDITIONAL TREATMENT
Radiation Therapy
- N/A
Additional Therapies
- N/A
Complementary & Alternative Therapies
- N/A

ONGOING CARE
PROGNOSIS
- If untreated, natural history is not well known
- Reported surgical success rates 70–99%

COMPLICATIONS
- Related to the diverticulum:
  - Stones
  - Carcinoma: Adenocarcinoma, transitional cell, squamous cell
  - Renal UTIs
  - Dysuria
  - Dyspareunia
  - Urinary incontinence
  - Storage or voiding symptoms
- Related to the surgery:
  - Infection
  - Bleeding
  - Urinary incontinence
  - Recurrent diverticulum
  - Urethrovaginal fistula
  - Urinary tract or necrosis
  - Bladder or urethral injury
  - Vaginal scarring or narrowing

FOLLOW-UP
Patient Monitoring
- VCUG after surgery at the time of catheter removal
- History and genitourinary exam on follow-up visits
- Additional studies if indicated based on history and exam findings

Patient Resources
http://www.urolgyhealth.org/urology/index.cfm?article=110

CLINICAL/SURGICAL PEARLS
- Classic symptoms include dysuria, dyspareunia, and post-void dribbling
- Definitive management requires transvaginal excision with a multilayer closure.
URETHRAL MASS

Bic N. Cung, MD
Jack H. Mydlo, MD

DESCRIPTION
- Urethral masses may be palpable; they are often visualized on cystoscopy or other imaging modalities.
- In females the most common differentials include: urachal cyst, periurethral/biunary duct cyst, prostatic urethral stenosis, periurethral abscess, and malignancy.
- In men inflammatory lesions such as: lichen sclerosus (LS) or balanitis xerothema obliterans (BXO), periurethral abscess and malignancy can be commonly seen.

EPIDEMIOLOGY
Incidence
- Incidence of urethral mass unknown.
- With respect to urethral malignancy:
  - African Americans twice as likely of developing primary urethral cancer as whites.
  - Primary urethral cancer at least twice as common in males as in females (1).
- Most common from 1st to 7th decades of life.

Prevalence
N/A

RISK FACTORS
- Malignancy:
  - Chronic UTIs may suggest anatomic problem such as diverticuli.
  - HPV-16 infection has been linked to urethral malignancy.
  - History of bladder cancer may suggest urethral malignancy.
- Inflammatory:
  - Most common from 5th to 7th decades of life.
  - African Americans twice as likely of developing primary urethral cancer as whites.
- Congenital:
  - Benign fibroepithelial polyp
  - Retention cysts of Cowper gland ducts
  - Urethral diverticulum
  - Pelvic MRI or CT often considered imaging study of choice for urethral neoplasms.

ASSOCIATED CONDITIONS
None

GENERAL PREVENTION
Self sexual practices can prevent STDs and decrease risk of inflammatory/infectious conditions.

DIAGNOSIS

HISTORY
- Age and sex of patient
- Malignancy: more common >50
- Prior history of bladder cancer may suggest urethral recurrence, particularly in men
- Sexual history
- General facts, gonorrhea may predispose to malignancy.
- Lower urinary tract symptoms:
  - Frequency, urgency, hematuria, or dysuria may be associated with stricture or malignancy.
  - Obstructive voiding symptoms such as weak stream, straining, and dribbling
- History of UTI
  - May be associated with urethral diverticulum

PHYSICAL EXAM
- General exam:
  - Assess for lower extremity edema.
- Lymph node assessment:
  - May be associated with urethral diverticulum
  - May be associated with urethral malignancy

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urate analysis
- Urine culture
- Urethral cytology
- Urethral secretions: Culture for gonorrhea, Chlamydia, and TB

Imaging
- Ultrasound to evaluate urethral stricture, diverticulum, and foreign body
- VUCs can help diagnose urethral diverticulum.
- Retrograde urethrogram (RUG) to assess for location and length of urethral stricture.
- Pelvic MRI or CT to assess for urethral diverticulum, metastasis to the pelvis and inguinal LNs, evidence of corporal invasion by carcinoma.
- Pelvic MRI often considered imaging study of choice for urethral neoplasms.

Differential Diagnosis
- Depends on clinical presentation and age of patient:
  - Children are more likely to have congenital disease
  - Young adults are more likely due to trauma or STIs/STDs
  - Older adults are at greater risk for primary or metastatic malignancy
- Congenital conditions:
  - Benign fibroepithelial polyp
  - Retention cysts of Cowper gland ducts
  - Urethral diverticulum
  - The 3 Ds: diverticulum, dysuria, dyspareunia, dribbling

Inflammatory
- Stricture disease secondary to gonoctocal urothitis
- Perirectal abscess
- Accessory gland cysts/abscesses
- Condyloma acuminata
- TB
- Lichen sclerosus (LS) or balanitis xerothema obliterans (BXO)
- Most common cause of mental stress in adults
- Traumatic:
  - Stricture disease secondary to injury: hematoma, foreign body
- Benign neoplasms:
  - Hyperplasia
  - Adenomatous polyps
  - Squamous papilloma
  - Transitional cell papilloma
  - Lichen plan
  - Inverted papilloma
  - Benign fibroepithelial polyp
  - Type 1 (benign), type 2 higher malignant potential and requires follow-up.
- Foreign body
  - Most common seen in patients with chronic catheter use.
  - Neoplastic:
  - Adenocarcinoma
  - Amyloidosis
  - Syncytial (parasquamous) gland, inflammation/ adenomalacation
  - Urethral carcinoma
  - More common in postmenopausal women
URETHRAL MASS

TREATMENT

GENERAL MEASURES
- Management is directed by the pathologic findings.
- Cystoscopic exam with biopsy is usually provided to diagnose.
- Imaging and bimanual exam will provide staging information in the case of malignancy.
- In cases with locally advanced disease, multimodality therapy using chemotherapy is sometimes used.
- Condyloma of the urethra: Intravesical 5-FU cream, anti-inflammatory cream.
- Biopsy with fulguration/laser ablation.
- Radiation is sometimes used.

Malignant neoplasms:
- Excision, fulguration, laser ablation.
- Biopsy for diagnosis.
- Excision, fulguration, laser ablation.

ADDITIONAL TREATMENT

Radiation Therapy
- May be indicated in some cases of urethral cancer to decrease local recurrence.
- In women, radiation therapy using biatriality and external beam radiation combination is a suitable alternative.

Complementary & Alternative Therapies
Combination of chemotherapy, radiation therapy, and surgery is recommended for advanced female urethral cancer.

ONGOING CARE

PROGNOSIS
- Depends on etiology of mass.
- Neoplasms:
  - Male: survival dependent on grade and stage of tumor.
  - Female: survival dependent on grade and stage of tumor.
- Urethral carcinoma in females of low stage has 70–90% cure rates with surgery.
- In females, this includes an anterior exenteration (urethrectomy, cystectomy with pelvic lymphadenectomy, hysterectomy with salpingectomy, and anterior vaginal wall).

COMPLICATIONS
- Depends on pathology and treatment.
- Urethral stricture: Complications secondary to instrumentation and treatment of urethral mass.

FOLLOW-UP

Patient Monitoring
- Cystoscopy and urethrocystogram every 6 mo for urethral carcinoma.
- Biopsy and surveillance for disease eradication.

URETHRAL SQUAMOUS-CELL CARCINOMA

Zachary L. Smith, MD
S. Bruce Malkowicz, MD, FACS

BASICS

DESCRIPTION

Squamous-cell carcinoma (SCC) of the urethra is a malignancy arising from the native squamous lining of the male and female urethra.

EPIDEMIOLOGY

Incidence

• Prevalence is higher in African American patients as compared to their white counterparts.
  – White males: 0.58 per 1,000,000
  – African American males: 2.3 per 1,000,000
  – White females: 0.43 per 1,000,000
  – African American females: 0.69 per 1,000,000

• Incidence increases steadily with age, more steeply in men as compared to women (1).

Prevalence

NR

RISK FACTORS

• Male urethral SCC:
  – Chronic irritation after prior intermittent catheterization (ICC)
  – History of sexually transmitted infection (STI): Nearly 25% of patients with urethral carcinoma will give history of STI.

• Urethral stricture disease (≥ 50% of patients).

• HPV

• History of external beam radiation therapy

• Female urethral SCC:
  – Leukoplakia
  – Chronic irritation
  – Porfus
  – Human papilloma virus
  – Visceral infections
  – Recurrent urinary tract infections
  – Possibly urethral diverticula: 4% of female urethral carcinoma is found within the diverticulum.

GENETICS

• Possibly linked to alterations in chromosomes Y, 2, 3, 4, 6, 7, 8, 11, and 20 (2).

• Notably, there have been no abnormalities described in chromosomes 9 and 17: those largely responsible for the development of urethral carcinoma.

PATHOPHYSIOLOGY

• Male urethral SCC:
  – Occurs in the male membranous urethra (80% SCC), bulbar urethra (80% SCC), and penile urethra (90% SCC).

• Female urethral SCC:
  – Occurs in the distal 2/3 of the female urethra.
  – Both male and female urethral carcinoma spread via direct local extension and via lymphatics:
    – Anterior urethra drains to superficial and deep inguinal nodes.
    – Posterior urethra drains to pelvic lymph nodes.

ASSOCIATED CONDITIONS

• Condyloma acuminatum
• History of STIs
• Presence of indwelling catheter
• Urethral diverticula
• Urethral stricture disease

GENERAL PREVENTION

Prevention of STIs with the use of barrier protection such as condoms

DIAGNOSIS

HISTORY

• Particular attention must be made to risk factors and associated GI conditions.

• Male urethral SCC:
  – Urethral bleeding
  – Perineal discomfort
  – Decreased force of stream

• Female urethral SCC:
  – Urethral bleeding
  – Palpable urethral mass
  – Urethral urgency or frequency
  – Induration of urethra or anterior vaginal wall

PHYSICAL EXAM

• Particular attention must be made to risk factors and associated GU conditions.

DIAGNOSTIC TESTS & INTERPRETATION

• Cytology of initial voided urine
• Urine culture
• Urine polymerase chain reaction for Neisseria gonorrhoeae and Chlamydia trachomatis
• Cystoscopy with biopsy or transurethral resection:

IMAGING

• Retrograde urethography/voiding cystourethrograph (RUG/VCGU):
  – Evaluates entire urethra
  – Aids in assessment for stricture disease, urinary fistula, or urethral diverticula

• Cross-sectional imaging (CT or MRI):
  – Aids in the determination of local involvement, spread to regional lymphatics, or invasion of contiguous structures

• MRI particularly helpful for assessment of corporal involvement

• CT-urography provides evaluation of upper urinary tract drainage and presence or absence of upper urinary tract neoplasia (more critical in patients with urethral urothelial carcinoma).

Diagnostic Procedures/Surgery

• Cystoscopy with biopsy or transurethral resection:
  – Gold standard in histologic diagnosis of urethral carcinoma
  – Cystoscopic appearance of fungating growth extending into urethral lumen

• Surgical specimen/excisional biopsy for concern for involvement of GI tract based upon physical exam or imaging

• Particularly important in cases of urethral adenocarcinoma to rule out a GI primary source

Pathologic Findings

Fungating tumor with varied cytologic differentiation ranging from well-differentiated lesions producing keratinized epithelium to anaplastic giant-cell tumors

DIFFERENTIAL DIAGNOSIS

• Condyloma acuminatum
• Benign neoplasms:
  – Hemangioma
  – Adenomatous polyps
  – Squamous papilloma
  – Urethral cell papilloma
  – Leukoplakia
  – Urethral caruncle (more common in postmenopausal women)

• Skene (periurethral) gland inflammation:
  – Sigmoidoscopy/colonoscopy if concern for malignancy

• Leukoplakia
• Neourethral abscess
• Skin infections:
  – Staphylococcus aureus
  – Enteric organisms
• Urethral fistula
• Urethral stricture
• Malignant neoplasms:
  – Primary urethral carcinoma:
    – Squamous cell
    – Adenocarcinoma
  – Carcinoma in situ
  – Squamous cell carcinoma
  – Adenocarcinoma

Alert

The clinician must have a very high index of suspicion when considering urethral carcinoma, considering the often insidious and nonspecific nature of the patient’s complaints.

570
URETHRAL SQUAMOUS-CELL CARCINOMA

TREATMENT

GENERAL MEASURES
- Treatment decisions based on sex, stage, and location of tumor.
- TNM staging (See Reference tables: TNM: Urethra Cancer)

MEDICATION

GENERAL MEASURES
- Male penile urethral SCC (3):
- Male bulbomembranous urethral SCC (3):

Localized disease:
- Preoperative chemotherapy or chemoradiotherapy has been shown to be of benefit over surgical resection alone.
- Cisplatin-based polychemotherapeutic regimens should be used.

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Male suburethral urethral SCC (3):
- Early lesions have been treated successfully with transurethral resection or local excision with end-to-end urethral anastomosis.
- Radical excision offers best chance at cure, with radical cystoprostatectomy, total penectomy, bilateral pelvic lymphadenectomy recommended.
- With locally advanced disease, consider en-bloc excision to include the pubic rami and urogenital diaphragm.
- Male penile urethral SCC (3):
- Transurethral resection, fulguration, or local excision may be employed for superficial low-grade tumors.
- For tumors involving the corpus spongiosum, partial penectomy with a 2-cm margin is treatment of choice if localized to the distal half of the penis.
- With involvement of the proximal penile urethra, total penectomy is required to obtain an adequate margin of excision.
- Biopsies of urethral margin are indicated in prius of palpable disease, as there has been no documented benefit of prophylactic lymphadenectomy.
- Distal female urethral carcinoma (5):
- Tumors of the distal urethra tend to be low-stage with cure rates of 70%-80% with local excision alone.
- External beam radiation therapy is also therapeutic option for distal female urethral carcinoma.
- Proximal female urethral SCC (3):
- For more likely to extend into the anterior vaginal wall and bladder.
- Requires anterior exenteration with wide resection of the vagina; pelvic lymph node dissection is often required to achieve negative surgical margins.

ADDITIONAL TREATMENT

Radiation Therapy
- Localized disease.
  - Male urethral SCC:
    - Preoperative radiation therapy for patients with early-stage lesions of the anterior urethra who refuse surgery.
    - Possible role in radiation for occasional advanced use with extensive resection.
  - Female urethral SCC:
    - Local pelvic disease:
      - Low-stage disease can be treated with external beam radiation or brachytherapy combined with 5-yr survival rates approaching 75%.
      - Although there appears to be some role to adjuvant external beam or brachytherapy in the treatment of locally advanced female proximal urethral urethral carcinoma, the possible role of radiation therapy remains unclear.
    - Advanced disease:
      - While surgical resection remains standard of care, preoperative radiation therapy combined with cisplatin-based chemotherapeutic regimens have been shown to give remarkable results in comparison to surgical resection alone.

Additional Therapies
N/A

Compensation & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Male urethral carcinoma (4):
  - 5-yr overall survival (OS): 42.3%.
  - 5-yr OS (superficial disease): 83.3%.
  - 5-yr OS (invasive disease): 35.7%.
  - 5-yr OS (anterior urethra): 69.1%.
  - 5-yr OS (bulbar urethra): 44.4%.
- Female urethral carcinoma (5):
  - 5-yr OS: 32%.
  - 5-yr OS (low-stage): 78%.
  - 5-yr OS (high-stage): 31%.
  - 5-yr OS (anterior urethra): 54%.
  - 5-yr OS (posterior urethra): 25%.

COMPLICATIONS
- Abscess
- Cystitis
- Incontinence
- Urethral stricture
- Urinary fistula

FOLLOW-UP

Patient Monitoring
- Most majority of recurrences occur within 1-2 yr following definitive therapy.
- Surveillance is not well established, but routine cystoscopy and urinary cytology for 1-2 yr, with increasing intervals between surveillance cystoscopy in the absence of recurrence seems reasonable.

Patient Resources

CODES
ICD9
- 189.3 Malignant neoplasm of urethra
- 199.9 Urethral stricture, unspecified
- 571.09 Personal history of other infectious and parasitic diseases

ICD10
- C89.3 Malignant neoplasm of urethra
- N39.9 Urethral stricture, unspecified
- Z91.19 Personal history of other infectious and parasitic diseases

CLINICAL/SURGICAL PEARLS
- Primary urethral SCC is a rare entity.
- Surgical excision is the mainstay of treatment.
- Distal tumors tend to be less advanced and more amenable to localized treatment.
- Proximal tumors tend to have a worse prognosis and require more aggressive treatment.
- Preoperative chemoradiotherapy may be used in advanced disease.
URETHRAL STRICTURE, MALE
Hunter Wessells, MD, FACS

ASSOCIATED CONDITIONS
- Trauma
- STD/STI
- Urethral instrumentation
- BPH
- Prostate cancer
- Lichen sclerosis/BXO

GENERIC PREVENTION
- Limited urethral instrumentation
- Appropriately sized instruments for transurethral procedures
- STD/STI prevention and early treatment (gonorrhea most common)

DIAGNOSIS
HISTORY
- Voiding symptoms
  - Hematuria
  - Reduction in stream
  - Post void dribbling
  - Urethral discharge
  - Hesitancy
  - Retention
- Prior surgery
- Transurethral surgery or manipulation
- Prostatitis
- Lichen sclerosis/BXO
- Urinary retention

PHYSICAL EXAM
- Palpable bladder with retention
- Lichen sclerosis/BXO
- Hypertrophy, meatal stenosis
- Thickened foreskin with glandular adhesions
- Evidence of discharge

DIAGNOSTIC TESTS & INTERPRETATION
- Urethroscopy with flexible cystoscope or hysteroscope
- Diagnostic Procedures/Surgery
- Proper size for transurethral procedures
- Injection of local anesthetic
- Dilatation and direct vision internal urethrotomy
- Abnormalities noted
- Residual urine
- Voiding symptoms
- Urethroscopy

TREATMENT

FIRST LINE
- No role for primary medical management of urethral stricture disease
- Medication
- General measures
- Imaging
- SURGERY/OTHER PROCEDURES
- Dilation and direct vision internal urethrotomy
- Dilation, cold DVIU, laser DVIU equivalent results
- Effective for short (<1 cm), large caliber (>15 Fr) strictures in which dilation or DVIU have not been previously attempted
- Use spanning in long, narrow or refractory strictures
- TECHNIQUES
  - Stabaler, balloon, sounds, filters, and followers
  - DVIU: Instil at 12:00 to limit bleeding
  - For balloon and DVIU, use helpful
  - 18 French Foley catheter for 48–72 h

Genetics
No known associations

PATHOPHYSIOLOGY
- Anterior urethral strictures
  - Compromised viability of corpus spongiosum secondary to trauma, inflammation or ischemia
  - Posterior urethral strictures
  - Pelvic fracture-associated urethral injury and related distraction defects
  - Scarring following TURP or radical prostatectomy

EPIDEMIOLOGY

DESCRIPTION
- A urethral stricture is a narrowing of the caliber of the anterior or posterior urethra. Progressive scarring can cause voiding symptoms possibly urethral obstruction
- True stricture of the female urethra is very rare.

RISK FACTORS
- Posterior urethral strictures
- Anterior urethral strictures
- Hypospadias, with or without prior repair
- Lichen sclerosis/balanitis xerotica obliterans (BXO)
- Trauma (straddle injury or pelvic fracture)
- Catheterization (usually prolonged)
- Previous TURP or radical prostatectomy
- Recurrent infection
- STD/STI associated with urethral stricture
- Urethral instrumentation
- Male urethral strictures in VA: 274/100k men
- Urethral strictures in Medicare: 4.5k/100k men
- Some data from Medicare suggests black Americans may have higher stricture rates

Prevalence
- Unknown

FACTORS
- Sexually transmitted infections (STIs) (sexually transmitted diseases [STDs]), particularly gonorrhea
- Posterior urethral injury in 6% of pelvic fractures and 15% of severe pelvic fractures
- Urethral strictures in VA: 274/100k men
- Urethral strictures in Medicare: 4.5k/100k men
- True stricture of the female urethra is very rare.
PROGNOSIS

Ongoing Care

Additional Reading

Urethroplasty: Anterior
- Short strictures (≤2 cm) amenable to excision and primary anastomosis
- Long strictures (>2 cm) require substitution with flap or graft
- Long strictures with narrow segment may need combination of resection and substitution (augmented anastomosis)
- Long strictures that are diffusely narrow may need staged urethroplasty with substitution (split-harvest urethroplasty)

- Urethroplasty: Posterior
  - Typically, excision and skin grafting required
  - Techniques used to bridge defect:
    - Urethral mobilization
    - Corporal separation
    - Inferior pubectomy
  - Suprapubic urethrostomy

- Grafts
  - Buccal mucosa widely used, favorable outcomes
  - No difference in success rates with ventral/dorsal graft position
  - Lichen sclerosus urethral reconstruction
  - One-stage or staged repairs using oral mucosa grafts are the most recommended

ADDITIONAL TREATMENT

Radiation Therapy

Additional Therapies
- Intermittent catheterization for 3–6 mo in select cases may improve patency rates
- Suprapubic placement is selected cases with inability to pass catheter or postoperatively following open repair
- Urolume™ stent approved for short bulbar urethral strictures; no longer manufactured
- Memokath™ stent may be useful after dilation or internal urethrotomy for recurrent bulbar strictures

Codes

ICD9

ICD10

CLINICAL/SURGICAL PEARLS

COMPLICATIONS

- Immediate
  - UTI
  - Bleeding
  - Urinary leak and/or fistula
  - Lower extremity compartment syndrome
  - Delayed
    - Postoperative erectile dysfunction may occur, but recovers by 3–6 mo.
    - Stress incontinence is rare, but can occur if internal and external sphincters are damaged—either prior to or at time of urethroplasty
    - Post-void dribbling
    - Bleeding
    - Urethrostomal fistula
    - Perineal cureuture

FOLLOW-UP

Patient Monitoring

- Recurrence most likely within 1 yr
- Uroflowmetry, PVR, and AUA-SS sufficient to monitor for recurrence; cystoscopy optional

Patient Resources

COMMENTS

ADDITIONAL READING

URETHRAL TRAUMA (ANTERIOR AND POSTERIOR)

Lee C. Zhao, MD, MS
Allen F. Morey, MD, FACS

ASSOCIATED CONDITIONS
- Pelvic fracture
- Pelvic hematoma
- Bladder injury
- Vaginal injury

GENERAL PREVENTION
- Seat belts
- Cautious instrumentation of the urethra to prevent iatrogenic injury

ALERT
- The amount of urethral bleeding does not correlate with the degree of injury.
- Pain with urination or inability to void is highly suggestive of urethral disruption in the trauma patient.

DIAGNOSIS

HISTORY
- Description of trauma and mechanism of injury
- Voiding history
- Retention
- Hematuria

PHYSICAL EXAM
- Classic clinical triad:
  - Blood at meatus:
  - Hematuria
  - Retention
- Grade V: complete or partial disruption of the bladder neck, rectum or vagina
- Grade IV: complete disruption
- Grade III: partial disruption
- Grade II: contusion
- Grade I: stretch injury

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- CBC, electrolytes, BUN, creatinine
- Urinalysis

Imaging
- Retrograde urography
- 30-degree oblique position with bottom leg flexed at knee and top leg straight.
- Place Foley catheter into Tossa navicularis, inflate balloon with 2–3 mL
- Injection of ~25 mL of contrast into urethra
- Extravasation of contrast indicates the location of the tear
- Complete injury usually has no contrast flow into the bladder
- CT is inadequate to evaluate urethral trauma
- Generally obtained for staging of associated injuries

TREATMENT

GENERAL MEASURES
- Perform retrograde urethrography (RUG) prior to placement of Foley catheter, avoid urethral instrumentation until urethral imaging if the patient is stable.
- If catheter has already been placed, do not remove it. Perform percutaneous RUG with pediatric feeding tube or angiocatheter.
- Establish prompt urinary drainage in patients with pelvic fracture associated urethral injury as typically unable to void and undergo aggressive resuscitation.
- Urethral injury confirmed be:
  - Extravasation on RUG or VCUG
  - Cystoscopy
- Classification of urethral injury can guide treatment decisions
  - EAU Classification of blunt urethral injury (1CE):
    - Grade I: stretch injury
    - Grade II: contusion
    - Grade III: partial disruption
    - Grade IV: complete disruption
    - Grade V: complete or partial disruption of posterior urethra with associated tear of the bladder neck, rectum or vagina

RISK FACTORS
- Pelvic fracture
- Penile/urethral instrumentation
- Perineal straddle injury
- Pelvic fracture

PATHOPHYSIOLOGY
- Anterior urethra injuries
  - Less common due to mobility of anterior urethra and protection of the pubovesical ligament
  - Penile fracture (often intercourse related) can cause anterior urethral injury
  - Penile constriction bands
  - Penile fracture (often intercourse related) can cause anterior urethral injury
- Posterior urethra
  - More common due to fixed location of urethra
  - Penetrating trauma (gunshot, stabbing)
  - Straddle injuries
  - Pelvic fracture
- More common due to fixed location of urethra
- Urethral instrumentation
  - Transurethral surgery using oversized resectoscopes
  - Chronic indwelling catheters
  - Catheter placement in patient with urethral stricture
  - False passage: instrument or catheter
  - Urethral injury: contusion, complete, partial
- Violation of Buck fascia, hematoma confined by Colles fascia
- Greater than 75% of patients with anterior urethral (AU) injury
- Place Foley catheter into fossa navicularis, inflate balloon with 2–3 mL
- 30-degree oblique position with bottom leg flexed at knee and top leg straight.
- Place Foley catheter into Tossa navicularis, inflate balloon with 2–3 mL
- Injection of ~25 mL of contrast into urethra
- Extravasation of contrast indicates the location of the tear
- Complete injury usually has no contrast flow into the bladder
- CT is inadequate to evaluate urethral trauma
- Generally obtained for staging of associated injuries

DIFFERENTIAL DIAGNOSIS
- Urethral injury: collision, complete, partial
- Injury to bladder neck, urethra
- Pelvic or vaginal injury

BASICS

DESCRIPTION
- Injury that disrupts the watertight integrity of the urethra, typically in male patients.
- Injury to the urethra in women is less common.

PREVALENCE
- Estimate 10–20% of anterior urethral stricture from injury (1).
- Occurs in 10% of pelvic fractures

INCIDENCE
- Joint has the highest risk of urethral injury
- Straddle fractures with diastasis of the sacroiliac joint has the highest risk of urethral injury

DIAGNOSTIC PROCEDURES/SURGERY
- Flexible cystoscopy
- Cystoscopy
- Retrograde urethrography
- VCUG
- Ultrasonography

ARTICLE 574
In an unstable trauma patient, a cautious attempt should be made to pass a urethral catheter. If there is any difficulty a suprapubic catheter can be placed and a retrograde urethrogram performed later [4].

In women, primary open repair is recommended for disruption of the urethra with associated tear of bladder neck and vagina (IIIc) due to risk of incontinence and vesicovaginal fistula.

Penetrating trauma:
- Immediate reconstruction is highly successful.
- High velocity projectiles create blast effect, making immediate reconstruction less reliable.
- Intracorporeal urethral injury: Place indwelling Foley for 7 days, followed by voiding cystourethrogram.

**ADDITIONAL TREATMENT**

**Radiation Therapy**

Additional Therapies:
- Repeat endoscopic treatment of traumatic urethral strictures may lead to longer strictures (IVB).
- In an unstable trauma patient, a cautious attempt can be made to pass a urethral catheter.
- If there is any difficulty a suprapubic catheter can be placed and a retrograde urethrogram performed later [4].

**MEDICATION**

First Line
- Antibiotics
- Second Line
- N/A

**SURGERY/OTHER PROCEDURES**
- Pelvic fracture and posterior urethral injury: Place large bore suprapubic catheter (16 Fr Foley) using percutaneous peel-away sheath.
- We advise against using small pigtail suprapubic catheters.
- For complex injuries with associated bladder trauma, open suprapubic tube placement with bladder inspection is suggested. Place suprapubic tube (SPT) in patients undergoing ORIF for pelvic fractures (24 Fr; high on bladder and tunneled through skin away from hardware).
- Open surgical realignment should be avoided due to high risk of urethral stricture formation.
  - Primary endoscopic realignment may be attempted but has a success rate of 25% (IIIR), but may delay the ultimate curative therapy for this condition. In our experience, traumatic strictures tend to be short and dense, and refractory to endoscopic treatment. Success rates for open anastomotic urethroplasty are greater than 90%.
- In women, primary open repair is recommended for disruption of the urethra with associated tear of bladder neck and vagina (IIIc) due to risk of incontinence and vesicovaginal fistula.

**COMPLICATIONS**
- Urethral stricture
- Erectile dysfunction

**FOLLOW-UP**

**Patient Monitoring**
- Recovery often complicated by other orthopedic and neurologic injuries.
- Anterior urethral injury: Good prognosis after primary repair.

**COMPLICATIONS**
- Urethral stricture
- Erectile dysfunction
- Follow-up
  - Perform reconstructive procedures at 4–6 mo
  - If endoscopic alignment has been performed, the suprapubic tube should be kept in place for at least one week after removal of urethral Foley. Most endoscopic alignment will fail at 1 wk.
  - Perform reconstructive procedures at 4–6 mo.

- Bladder Trauma
- Perine. Trauma
- Urethra, Strictures, Male
- Urethra, Trauma (Anterior and Posterior) / Images

**ADDITIONAL READING**

- Retrograde urethrography is considered the gold standard for evaluating urethral injury.
- Most pelvic fracture associated injuries occur in the posterior urethra.
- Penetrating urethral injury should be managed with suprapubic catheter and delayed definitive repair.
- When placing a suprapubic catheter, should use a large bore Foley catheter placed via a peel away sheath.
- Urethral injury in women associated with bladder neck or vaginal injury should be repaired primarily.
- Anastomotic repair of traumatic strictures has a high success rate.
URETHRITIS, GONOCOCCAL AND NONGONOCOCCAL

Daniel C. Parker, MD
Jack H. Mydlo, MD

ASSOCIATED CONDITIONS
- Other STDs/STIs
- Pendulous urethral stricture
- Epididymitis/orchitis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urine analysis
  - Obtain 1–4 h after voiding
  - ≥ 15 PMN leukocytes per HPF of spun sediment in the first-void urine specimen
- Positive leukocyte esterase on urine dip in the absence of UTI suggests urethritis
  - Up to 30% of patients with urethritis will not have WBC in the urine
- Urethral smear for gram-stain and culture
  - Calcium alginate swab inserted 1–2 cm into urethra best to obtain 1–2 hours after voiding
  - Culture plated on Thayer-Martin media for GU
- Sensitivity of DNA targeted assays is improving
  - NAAT available for: C trachomatis and N gonorrhoeae. Labs can also test for Mycoplasma, Ureaplasma, and Trichomonas vaginalis but these assays are no commonly performed since they are very costly and may not alter the recommended antibiotic regimen

Pathologic Findings

DIFFERENTIAL DIAGNOSIS
- GU
  - Nongonococcal urethritis
    - Chlamydia trachomatis
    - Mycoplasma genitalium
    - Trichomonas vaginalis
  - Ureaplasma urealyticum
  - Uncommon infectious causes: TB, adenovirus, uropathogenic Escherichia coli (unprotected anal intercourse), herpes simplex, cytomegalovirus

- Urethral diverticulum
- Reiter’s arthritis
- Reactive urethritis (formerly Reiter syndrome) associated with conjunctivitis, arthritis, and tenosynovitis
- No growth on culture
- Minimal number of leukocytes in urethral smear or urine
- Mikulicz’s: Urethral irritation from detergents, soap bubble, lather, spermicides, contraceptives, manipulation, and/or foreign body insertion.

  - No growth on culture
  - Minimal number of leukocytes in urethral smear or urine
  - Mikulicz’s: Urethral irritation from detergents, soap bubble, lather, spermicides, contraceptives, manipulation, and/or foreign body insertion.
TREATMENT

GENERAL MEASURES
- Cases are reportable to health department.
- Sexual intercourse should be avoided until cure.
- Sexual partners within 60 days of diagnosis or symptoms should be evaluated and treated.
- Dual treatment for both N. gonorrhoeae and C. trachomatis is recommended.

ALERT
The CDC now recommends against the use of quinolones and oral cephalosporins for treatment of gonococcal urethritis in the US due to widespread bacterial resistance (31A).

MEDICATION

First Line
- GU:
  - CDC recommends dual therapy for GU and NGU
    - Ceftriaxone 250 mg IM once
    - Erythromycin 500 mg PO q.i.d. for 7 days
    - Azithromycin 1 g PO once, or doxycycline 100 mg PO b.i.d. for 10-14 days
- NGU:
  - Azithromycin 1 g PO once, or doxycycline 100 mg PO b.i.d. for 10-14 days

Second Line
- GU:
  - Cefixime 400 mg PO once
  - Doxycycline 300 mg PO b.i.d. for 10-14 days
- NGU:
  - Ceftriaxone 250 mg IM once
  - Doxycycline 100 mg PO b.i.d. for 10-14 days

SURGERY/OTHER PROCEDURES
- Surgery typically not indicated

ADDITIONAL TREATMENT
- Radiation Therapy: N/A
- Additional Therapies
  - Patient education
  - Proper use of condoms and safe sexual practice
  - Reduce number of sexual partners
  - Evaluation and treatment of sexual partners at risk (31A)
- Complementary & Alternative Therapies: N/A

ONGOING CARE

PROGNOSIS
- Generally good prognosis with treatment for both GU and NGU
- Systemic manifestations of gonococcal dissemination are rare today:
  - Arthritis
  - Dermatitis
  - Meningitis
  - Endocarditis

COMPLICATIONS
- GU:
  - Pelvic inflammatory disease
  - May lead to abscess
  - Urethral stricture
  - Epididymitis/orchitis
  - May lead to testicular atrophy or infertility
  - Prostatitis
  - May lead to abscess
  - NGU:
    - Emotional sequelae are common
    - Fear of loss of sexual function or guilt may produce depression
    - Epididymitis and/or nonspecific prostatitis
    - Usually does not cause severe physical complications in men

FOLLOW-UP
- Patient Monitoring
  - GU and NGU:
    - Post therapy culture and urethral smear to confirm response to therapy
- Patient Resources
  - CDC: STD fact sheets: http://www.cdc.gov/std

CODES
- ICD9: 098.0 Gonococcal infection (acute) of lower genitourinary tract
  - 099.40 Unspecified other nongonococcal urethritis (NGU)
  - 131.02 Trichomonal urethritis
- ICD10: A51.01 Gonococcal cystitis and urethritis, unspecified
  - A59.03 Trichomonal cystitis and urethritis
  - A72.1 Non-specific urethritis

CLINICAL/SURGICAL PEARLS
- GU is caused by the gram-positive diplococci Neisseria gonorrhoeae.
  - NGU is most commonly caused by Chlamydia trachomatis.
- Up to 35% of cases of GU are coinfected with NGU.
- The CDC recommends simultaneous treatment for both GU and NGU in patients presenting with urethritis.
- Sexual partners within 60 days of diagnosis or symptom onset should be evaluated and treated.
URGENCY, URINARY (FREQUENCY & URGENCY)
Jessica M. DeLong, MD
Kurt A. McCammon, MD, FACS

BASICS

DESCRIPTION
- Urge is the complaint of a sudden compelling desire to void that is difficult to defer while frequency is the complaint by a patient that he or she voids too often.
- Urgency: – Urge is the most common symptom of overactive bladder (OAB).
- Urge incontinence is involuntary leakage of urine precipitated by the above symptom (1).
- Frequency: – There is no minimum number of voids.
- Nocturia is the complaint of waking at night to void one or more times.
- These are classified as storage symptoms.

RISK FACTORS
- Genetics
- Pathophysiology
  - Inflammation
  - Narrowing (IC/PBS)
  - Diverticulosis
  - Polyuria

ASSOCIATED CONDITIONS
- Bladder outlet obstruction
- Diverticulosis
- Dysfunctional voiding
- Interstitial cystitis (IC/PBS)
- OAB
- Urinary tract infection (UTI)
- Vaginitis

GENERAL PREVENTION
- Treat any underlying condition (eg, UTI)
- Maintain good voiding habits and regular bowel pattern

DIAGNOSIS

HISTORY
- Use validated questionnaires when possible
  - International prostate symptom score (IPSS), (IPSS-GQ)
  - Urgency sensation scale
- Initial voiding symptoms:
  - Urgency, frequency, urge incontinence, nocturia
- Obstructive voiding symptoms:
  - Hematuria, slow stream, post-void dribbling, retention
- Consider causes of bladder outlet obstruction
- Other medical history
  - Stone disease
  - Bladder malignancy
- Symptoms of infection
  - Polymerase chain reaction (PCR) – Tissue
- Episodes of gross hematuria
- Bowel habits
- Sexual function
- Current medications
  - Diuretics, alpha blockers
  - Tobacco use
  - Family history
  - Pregnancy
  - Urinary incontinence

PHYSICAL EXAM

- Urine analysis (UA) – Exclude other pathology
  - Specific gravity
  - Protein
  - Microhematuria necessitates further work up
  - Cystoscopy, triphasic CT
  - Glucose: Assess for diabetes
  - Proteins: Assess for medical renal disease
  - Obtain culture if UA suggestive of infection
  - Urinary cytology to rule out urothelial carcinoma

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urine analysis (UA) – Exclude other pathology
  - Specific gravity
  - Protein
  - Microhematuria necessitates further work up
  - Cystoscopy, triphasic CT
  - Glucose: Assess for diabetes
  - Proteins: Assess for medical renal disease
  - Urinary cytology to rule out urothelial carcinoma

Imaging
- Radiologic imaging – If bladder outlet obstruction (BOO) suspected
  - If hematuria or persistence symptoms
  - If conservative therapy fails
  - If stones suspected, non-contrast CT

Alert
- If UA suggests infection or hematuria, appropriate evaluation is key.

Diagnostic Procedures/Surgery
- Check post void residual (PVR)
- Cystoscopy
- If hematuria or persistent problems
- May direct bladder pathology tumor, calculus, BOO
- Urodynamics (UDS)
  - If conservative therapy fails
  - Can help define treatment options and evaluate for neurogenic component

Pathologic Findings
- Dependent upon etiology

DIFFERENTIAL DIAGNOSIS

- Inflammation: UTI, urethritis
- Radiation cystitis
- IC/PBS
- Trauma—local or neurologic
- Foreign body
- Neurologic condition (ie, spina bifida, spinal cord injury, neuropathy)
- Neoplasm—urologic or neurologic by local extension
- Urothelial carcinoma, especially CIS
- Other causes of urinary frequency
- Urolithiasis
- Polyuria
- Drugs—diuretics, irritants
- Gynecologic/vaginitis, pregnancy
TREATMENT

GENERAL MEASURES
- Based on underlying etiology
  - Treat UTI with appropriate antibiotics
  - Initiate appropriate workup and management of hematuria
- In general, treatment is divided into:
  - Conservative (behavioral)
  - Pharmacotherapy
  - Surgery

MEDICATION

First Line
- Choice based on etiology
- Antimuscarinics are used to inhibit detrusor contraction by competitively inhibiting muscarinic cholinergic receptors. Common side effects: dry mouth and constipation. maximal effect after 3 mos
  - Oxybutynin
    - 5 mg PO TID; XL, 15 mg daily BID
    - Transdermal patch 3.9 mg/24 h: may be good option to avoid cognitive side effects
  - Tolterodine 1–2 mg PO BID
  - Darifenacin 7.5–15 mg PO daily
  - Solifenacin 5–10 mg PO daily
  - Tamsulosin 0.4 mg PO qhs

- P-3 adrenergic receptor antagonists: A newer drug, induces detrusor relaxation
  - Mipolargon 25–50 mg PO daily
  - α-blockers are used to decrease outflow obstruction due to prostatic hyperplasia. Common side effects: dizziness, retrograde ejaculation
    - Tamsulosin 0.4 mg PO qhs
    - Alfuzosin 10 mg PO daily
  - Dutasteride 0.5 mg PO daily
  - Tamsulosin 0.4 mg PO qhs

- 5α-reductase inhibitors are used to lower DHT in men with prostatomegalia
  - Finasteride 5 mg PO daily
  - Dutasteride 0.5 mg PO daily

Second Line
- PES/UTIs
  - Documented efficacy for men with lower urinary tract symptoms (LUTS)/OAB
  - FDA approved for signs and symptoms of BPH
  - With or without erectile dysfunction
  - Imiquimod
    - No good quality RCTs
  - Estrogens (vaginal superior to systemic)

In general, treatment is divided into:
- Conservative (behavioral)
- Pharmacotherapy
- Surgery

BASED ON UNDERLYING ETAIOLOGY
- Generally a long-term problem; dependent on etiology
- Prognosis
- Generally a long-term problem; dependent on etiology
- Follow-up
- Depends upon etiology, treatment, response
- Often periodic visit with voiding diary, uroflow, PVR

PATIENT MONITORING
- Depends upon etiology, treatment, response
- Often periodic visit with voiding diary, uroflow, PVR

PATIENT RESOURCES
- MedHelpDoc frequent or urgent urination.

REFERENCES

ADDITIONAL TREATMENT

Radiation Therapy

- Additional Therapies
  - Behavioral therapy is first-line
    - Bladder training may include biofeedback and pelvic floor physical therapy
    - Timed voiding
    - Kegel exercises may be of benefit

Complementary & Alternative Therapies

ON GOING CARE

URGENCY, URINARY (FREQUENCY & URGENCY)

ICD9
- 596.51 Hypertonicity of bladder
- 788.41 Urinary frequency
- 788.63 Urgency of urination

ICD10
- N02.81 Overactive bladder
- R35.0 Frequency of micturition
- R35.15 Urgency of urination

CLINICAL/SURGICAL PEARLS

- Hematuria warrants appropriate workup. May be a presentation of genitourinary malignancy.
- Anticholinergics are contraindicated in patients with untreated narrow-angle glaucoma.
- Combination of antimuscarinics plus α-blockers may be better than either alone for men with LUTS/OAB.
- Use anticholinergics with caution in elderly patients, as cognitive effects may be pronounced.
- Use of intravesical estrogen for postmenopausal women may worsen incontinence.
URINARY RETENTION AFTER STRESS URINARY INCONTINENCE SURGERY IN FEMALES
Bradley C. Gill, MD, MS
Sandip P. Vasavada, MD, FACS

DIAGNOSIS

HISTORY
Details of retention
- Timing of symptom onset with regard to surgery
- Duration of symptoms and consistency with voiding
- Associated with discomfort, distention, or incontinence

Rheologic conditions
- Detrusor hypocontractility or urodynamics studies
- Episodes of cystolithiasis
- Recurrent urinary tract infections
- Cystocele
- Rheologic interventions
- Intact detrusor botulinum toxin injections
- Previous midurethral sling or retropubic urethropexy
- Other interventions
- Abdominopelvic surgery, radiation, or injury
- Spleen surgery or injury
- Current medications
- Antimuscarinics or anticholinergics
- Alpha adrenergic agonists
- Diabetes mellitus

PHYSICAL EXAM
- Visual inspection of the abdomen and suprapubic area
- Abdominal palpation with attention to the suprapubic area
- Visual inspection of the external genitalia for discharge or bleeding
- Speculum examination
- Swelling or bulging anterior vaginal wall
- Incisional discharge or bleeding
- Cystocele
- Pus from external genitalia, vaginal wall, or pelvic floor muscles
- Urethral or anterior vaginal wall bulging or tension
- Tension and mobility of surgically placed sling or sutures
- Pelvic floor muscle tension, spasm, or tenderness

TREATMENT
GENERAL MEASURES (2,3)
- Catheterization and observation of iatrogenic obstruction
- Trial of intermittent catheterization to observe for resolution
- Considerative intervention if no resolution within 3 mo

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum electrolytes
- Blood counts

Imaging
- Bladder ultrasound
- Abdominopelvic surgery, radiation, or injury

DIFFERENTIAL DIAGNOSIS
- Bladder diverticulum
- Detrusor hypocontractility
- Occult urinary retention or incomplete emptying
- Spleen surgery or injury
- Cystocele
- Medication
- Diabetes mellitus

BASICS

DESCRIPTION
- Inability to void spontaneously following surgery for stress urinary incontinence
- Voiding with Valsalva or straining following surgery for stress urinary incontinence
- Procedure performed may be either midurethral sling or retropubic urethropexy

EPIEDEMOLOGY
- Incidence
  - Estimated 3–11% for midurethral sling
  - Estimated 3–7% for retropubic urethropexy
- Prevalence
  - More common with retropubic or transvaginal slings than transobturator slings
  - Likely more common with synthetic than biologic sling materials
- Episodes are generally transient and last days to weeks but resolution up to 3 mo can occur

RISK FACTORS (1)
- Weak detrusor contraction or incomplete voiding preoperatively
- Procedure done with “tension” rather than “tension-free” placement
- Inability to urinate or elevated post-void residual postoperatively

PATHOPHYSIOLOGY
- Iatrogenic obstruction by extrinsic compression
- Retropubic suspension can cause urethral “kinking”
- Incisional discharge or bleeding
- Cystocele
- Pus from external genitalia, vaginal wall, or pelvic floor muscles
- Urethral or anterior vaginal wall bulging or tension
- Tension and mobility of surgically placed sling or sutures
- Pelvic floor muscle tension, spasm, or tenderness

ASSOCIATED CONDITIONS
- Bladder diverticulum
- Cystocele
- Cystolithiasis
- Detrusor hypocontractility
- Recurrent urinary tract infections
- Urethral stricture
URINARY RETENTION AFTER STRESS URINARY INCONTINENCE SURGERY IN FEMALES

• Emergent bladder drainage for an impassable urethra
  – Operative sling revision pending anticipated delay for arranging surgery
  – Suprapubic aspiration and drainage at bedside
  – Percutaneous nephrostomy tubes if no other options are possible
• Careful urethral dilation may be considered soon after surgery
• Evacuation of hematoma if suspected as etiology of urethral compression

MEDICATION

First Line
N/A
Second Line
N/A

SURGERY/OTHER PROCEDURES

• Elective bladder diverticulectomy as indicated
• Transvaginal retropubic urethrolysis if more conservative measures fail

ADDITIONAL TREATMENT

Radiation Therapy
N/A
Additional Therapies
N/A
Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

• Excellent considering multiple options
• Major risk is incontinence recurrence
  – 15–20% recurrence of stress urinary incontinence symptoms

COMPICATIONS

• Infection
• Urinary/bladder injury
• Recurrent incontinence

FOLLOW-UP

Patient Monitoring

• Office follow-up every 7–14 days for trials of voiding
  if an indwelling catheter placed
• Standard postoperative follow-up if a surgical intervention is pursued

Patient Resources
N/A

CODES

ICD9

599.60 Urinary obstruction, unspecified
788.29 Other specified retention of urine
997.5 Urinary complications, not elsewhere classified

ICD10

N36.8 Other specified disorders of urethra
N99.89 Oth postprocedural complications and disorders of GU sys
R33.8 Other retention of urine

CLINICAL/SURGICAL PEARLS

• Think about how sling vectors impact function.
• Many cases will resolve themselves with time.
• If consistently occurring change the technique.
URINARY RETENTION, ADULT FEMALE
Mary K. Powers, MD
Raju Thomas, MD, MHA, FACS

DIAGNOSIS

HISTORY
• Complaints of frequency, decreased force of stream, urgency or urge incontinence, or UI are indicative of bladder outlet obstruction (BOO)
• Feeling of vaginal urge
• History of stroke, diabetes, MS, Parkinson’s disease, "back problems," neurologic conditions, depression
• Chronic narcotic medication use
• Chronic constipation
• Use of psychotropic medication

PHYSICAL EXAM
• Examine bladder distension
• Examine abdomen to evaluate any prior surgeries
• Motor/sensory tone to rule out neurologic disorder
• History of stroke, diabetes, MS, Parkinson’s disease, feeling of vaginal bulge, complaints of frequency, decreased force of stream, urgency or urge incontinence, or UTI are indicative of bladder outlet obstruction (BOO)
• Tension-free vaginal tape has lowest range of reoperation
• Retropubic suspension can cause urethral "kinking"
• 2–8% of women require reintervention. Retropubic suspension can cause urethral "kinking"
• Anticholinergics (26%)—most commonly following anti-incontinence surgery
• Retention is frequently self-limited and will resolve within 6–12 wk following anti-incontinence surgery
• Manage with catheterization or clean intermittent catheterization

• Anatomic:
  - Urethral stricture (13%)
  - Ectopic ureterocele
  - Urethral diverticulum (3%)
  - Urethral malignancy
  - Bladder neck obstruction
  - Pelvic organ prolapse (24%)
  - Dysfunctional Voiding (5%)
  - Pseudodystonia—severe spasticity of sphincter without nerve stimulation (rare)

  • Fowler syndrome—young women without neurologic disease. Highly responsive to neuromodulation.
  • Higher incidence of depression and polycystic ovarian syndrome

• Neurologic
  - Detrusor sphincter dyssynergia (5%)
  - Pharmacologic:
    - Anticholinergic, opioid, and other narcotic medications
    - Anticholinergics: Atropine, belladonna, benztropine, mecamylamine
    - Cyclic antidepressants, phenothiazines, ipratropium bromide
  - Antispasmodics
    - Tricyclic antidepressants
    - Anticholinergic: Atropine, belladonna, benztropine, mecamylamine, cyclic antidepressants, phenothiazines, ipratropium bromide
  - Antispasmodics
  - Trospium, oxybutynin, solifenacin, hyoscyamine
  - Anticholinergic: Atropine, belladonna, benztropine, mecamylamine
  - Cyclic antidepressants, phenothiazines, ipratropium bromide

  • Antihistamines
  • Tamsulosin (alpha-1 Agonists: Cold preparations, ephedrine derivatives, antihistamines

  • Narcotics
  • Detrusor muscle relaxants: Tolterodine, trospium, indanylth, solifenacin, hyoscyamine, NSAIDs

  • Psychogenic
  • Myogenic (eg, detrusor acontractility)
URINARY RETENTION, ADULT FEMALE

TREATMENT

GENERAL MEASURES (2)
- Treatment based on underlying cause
- Stop medications predisposing to retention
- Evaluation and management of chronic constipation/bowel dysfunction
- Foley catheterization vs. clean intermittent catheterization (preferred) to manage acute retention

MEDICATION

First Line
- Alpha-adrenergic blockade can be useful in patients with dysfunctional voiding
  - Tamsulosin: 0.4 mg daily
  - Doxazosin: 1–4 mg daily
  - Terazosin: 1–5 mg daily
  - Prazosin: 1–5 mg daily

Second Line
- Baclofen for patients with neurologic causes of dysfunctional voiding
  - 5 mg TID, increase 15 mg q3 days, max. 80 mg divided TID/QID

SURGERY/OTHER PROCEDURES
- For iatrogenic causes, intervention should be postponed for a period of 12 wk to allow for stabilization of symptoms
  - Urethral dilation for urethral strictures. Caution not to cut too deep and develop fistulas
  - Refractory strictures can undergo reconstruction with vaginal flap

ADDITIONAL TREATMENT

Radiation Therapy
NA

Additional Therapies
- Urethral dilation for urethral strictures. Caution because this can lead to fibrosis and is falling out of favor
- Clean intermittent catheterization may be best choice for patients with intractable bladder outlet obstruction
- Constipation management
  - Colace 100 mg 1 tab by mouth BID
  - Magnesium citrate 250 mL PO

Complementary & Alternative Therapies
Concurrent evaluation and management by gastroenterology

ONGOING CARE

PROGNOSIS
- Depends on the etiology
  - Iatrogenic retention following slings has a good success rate with urethral dilation up to 90%
  - A blockage shows 50% improvement in PVR, symptoms, and flow rate

COMPLICATIONS
- Urethral stricture can lead to development of stress incontinence
- Bladder neck incision can lead to incontinence, vesicovaginal fistula, or need for repeat procedures
- Urethral dilation can cause recurrent stricture and fibrosis

FOLLOW-UP

Patient Monitoring
- Repeat urodynamic studies are recommended if problem persists
- Videourodynamics should be done if concern for bladder neck obstruction
- Neurologic evaluation if new diagnosis of MS, Parkinson’s disease

Patient Resources

CODES

URINARY INCONTINENCE, ADULT MALE

583
URINARY RETENTION, ADULT MALE
Akhil Das, MD, FACS
Amar J. Raval, MD

BASICS

DESCRIPTION
Urinary retention is the inability to properly empty the urinary bladder. It can be further classified as acute and chronic.

- Acute retention of urine is defined by the International Continence Society (ICS) as a painful, palpable, or percussionable bladder, when the patient is unable to pass any urine.
- Chronic retention of urine is defined by the ICS as a non-palpable bladder, which remains palpable or percussionable after the patient has passed urine. Such patients may be incontinent.

EPIDEMIOLOGY
Incidence
Incidence increases with age in males (~10% in men aged 70 yr).

Prevalence
Exact prevalence is difficult to estimate.

RISK FACTORS
- General disease, herpes zoster, drugs, psychogenic, neurologic disease, bladder calculus, recent surgery (especially with epidural or spinal anesthesia), groin surgery such as hernia repair, prostate brachytherapy, stroke, pelvic trauma.
- Elderly: BPH, prostate cancer, history of retention, urologic procedures or instrumentation, medications, prostatitis, urethral carcinoma (rare cause).
- Recent inguinal/pelvic surgery (ie, hernia).

HISTORY
- Acute retention: sudden onset of inability to void more than small volumes of urine
- Associated with an uncomfortable sensation and a distended bladder.

Chronic retention: longstanding inability to completely void, with occasionally large PVRs, but not usually associated with discomfort.

Retention may suggest infection or BPH:
- Prostate:
  - Recent blood loss, may indicate prostatitis, recent prostate surgery, etc.
  - Hematuria suggestive of infection, tumor, or calculus
  - PSA usually not checked acutely due to false positive

DIAGNOSIS

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM

- Painful, palpable, or percussionable bladder
- Urinary leakage

Lab
- Chemistry: BUN and creatinine may be abnormal in patients after surgery, due to bandaging of the perineum, or after regional anaesthesia such as an epidural anesthetic.
- Urologic:
  - Ultrasound: Can delineate bladder calculi, prostate size, hydronephrosis, bladder wall thickening
  - CT of abdomen/pelvis: CT of abdomen/pelvis is useful for diagnosis of acute and chronic urinary retention
  - Renal/bladder US: Can be obtained if diagnosis uncertain
  - DRE: Boggy, tender prostate suggests prostatitis
  - Nodularity suggests cancer
  - Symmetrically enlarged prostate suggests BPH
  - Assess for severe urgency and/or pain on palpation

DIAGNOSTIC PROCEDURES/SURGERY

- Radial abdominal mass: Assess for severe urgency and/or pain on palpation
- DRE
- Prostatic biopsy
- Bladder washout
- Transurethral resection of prostate
- Cystoscopy
- Nephrostomy
- Urethral dilatation
- Retrograde urethrogram
- ICS as a non-palpable bladder
- Release of bladder neck obstruction or with a known history of neurologic voiding dysfunction
- Infection, bleeding, or over distension is the usual precipitating event
- Damage to bladder results in prompt symptomatic relief.

Although acute retention is usually thought of as painful, in certain circumstances pain may not be a presenting feature.

- When due to prostatic intra-urethral disc, post partum, or after regional anesthesia such as an epidural anesthetic.
- The retention volume should be significantly greater than the expected normal bladder capacity.

In patients after surgery, due to bandaging of the lower abdomen or abdominal wall pain, it may be difficult to detect a painful, palpable, or percussionable bladder.

ASSOCIATED CONDITIONS

- Diabetes
  - Disease of prostate
  - BPH
  - Prostate cancer
  - Prostatitis
- Neurologic conditions
  - Neurogenic bladder
- Multiple sclerosis
- Cerebrovascular accident
- Parkinson disease
- Spinal cord injury
- Demyelinating disorders
- UUI
- Recent hemia or other surgery

PATOPHYSIOLOGY

Most commonly occurs in patients with preceding bladder outlet obstruction or with a known history of neurologic voiding dysfunction.

Infection, bleeding, or over distension is the usual precipitating event.

Bladder outlet obstruction results in prompt symptomatic relief.

- Pain: Bone pain and weight loss suggest prostate cancer
- Spinal cord injury or pelvic trauma
- Recent surgery, especially in those with spinal or epidural anesthetics
- Diabetes mellitus
DIFFERENTIAL DIAGNOSIS
- Generally either bladder outlet obstruction or bladder dysfunction:
  - Anatomic:
    - Peri: Phimosis, paraphimias, meatal stenosis, foreign-body constriction
    - Prostatic: BPH, prostate cancer, bladder neck contracture, prostatitis, prostatic infection
  - Trauma:
    - Urinary disruption
  - Neurologic:
    - Motor paralytic: Spinal shock, spinal cord injuries, spina bifida or meningomyelocele
    - Sensory paralytic: Tabels dorsalis, diabetes, multiple sclerosis, and peri-ocular amnesia
    - Syringomyelia, myelopathy, subluxation
    - Hepeza zoster, poliomyelitis
  - Hematologic:
  - Drugs: see *Risk Factors*

TREATMENT
GENERAL MEASURES
- Acute urinary: Catheterization for decompression
- In men with BPH: consider immediate urological therapy to improve likelihood of successful catheter removal
- Some consider suprapubic tube (SPT) superior in the management of short-term retention
- Chronic retention: Clean intermittent catheterization preferred over long-term indwelling catheter
- Definitive management may involve medications, surgical intervention, or chronic catheterization strategies
- Unindicated studies may be required to establish diagnosis
- Treatment should be directed toward cause, with goal of preventing future episodes
- Antibiotics as indicated for infection
- Decrease or stop medications that can contribute to voiding dysfunction

MEDICATION
First Line
- Most medications are used for BPH: may also help with transient postoperative retention (2).
  - α1-Adrenergic blockers: Relax proximal bladder neck smooth muscle tone, most useful for acute retention
    - Alphazosin (10 mg)
    - Doxazosin start 1 mg/d to max. 10 mg
    - Silodosin (8 mg)
    - Terazosin start 0.4 mg/d to max. 0.8 mg
  - α2-Agonists: Lower urinary tract symptoms (LUTS)
  - α5-Reductase inhibitors: Reduce prostatic volume, longer-term effects
    - Finasteride or dutasteride
    - Side effects: Decreased libido and sexual dysfunction
  - Reduce PSA by ~50% and ambition should be used when evaluating risk for cancer
  - Combination therapy (α-adrenergic blocker + 5α-Reductase Inhibitor)
  - Tailor 2.5–5 mg/5 mg/5 mg/day to treat both lower urinary tract symptoms (LUTS) and erectile dysfunction (ED)

Second Line
- Behandol (10–50 mg PO tid-qid)
  - Direct cholinergic stimulant; increases detrusor tone
  - Indicated for the treatment of acute postoperative and postpartum obstructive (Functional)
  - Urinary retention and for neurogenic atony of the urinary bladder with retention
- Side effects: Dizziness, nausea, bronchoospasm, hyper tension, tachycardia, seizure

SURGERY/OTHER PROCEDURES
- If catheter placement fails, bedside or inoperative cystoscopy can be performed:
  - Cystoscopy is usually diagnostic and can delineate urethral stricture, false passage, bladder neck contracture, and obstructing prostate tissue.
  - Once bladder is entered under direct vision, a wire can be placed and dilations sequentially performed. The wire can then be used to allow passage of a Council tip catheter.
- If cystoscopy is unsuccessful, consider SPT placement
  - Open SPT preferable in patients with history of multiple abdominal surgeries
  - If no prior surgery, place SPT via percutaneous approach

ADDITIONAL TREATMENT
Radiation Therapy

Additional Therapies

COMPLEMENTARY & ALTERNATIVE THERAPIES

ONGOING CARE

PROGNOSIS
- ~85% of patients with an episode of urinary retention will recur if untreated
- Prevention of recurrence underscores management decisions

COMPLICATIONS
- Bladder rupture in acute urinary retention; usually associated with trauma
- Relief of chronic prolonged obstruction may result in post-obstructive diuresis or major hemorrage secondary to bladder mucosal disruption or tearing of bladder vessels, hematuria may require evacuation of clots
- Significant hypotension may occur secondary to vaso-vagal response
- Longstanding, untreated urinary retention can lead to reflux nephropathy and permanent vesicoureteral dysfunction

FOLLOW-UP
- Monitoring of electrolyte imbalance and fluid resuscitation in post-obstructive diuresis (>200 mL/h)
- Patient with signs of infection or impaired renal function should be admitted and observed

Patient Resources
URINARY RETENTION, PEDIATRIC

Dana A. Weiss, MD
Douglas A. Canning, MD, FACS

BASICS
DESCRIPTION
Urinary retention is the inability to properly empty the urinary bladder. Can be acute or chronic partial or complete.
- Acute
  - Uncommon in children
  - Acute onset of inability to void for over 12 h
  - Associated with uncomfortable often painful sensation and distended bladder.
- Chronic
  - Inability to void over long period of time
  - Usually asymptomatic

EPIDEMIOLOGY
Incidence
Not reported
Prevalence
2:1 boys:girls

RISK FACTORS
- Acute onset
  - Surgery, narcotic use, immobility, urinary tract infection (bacterial or viral), local inflammation (balanitis, meatal stenosis, labial adhesions, cellulitis), constipation, incarcerated inguinal hernia, acute neurologic inflammatory processes, invasive mass, drug related
- Chronic
  - Dysfunctional voiding, Hinman syndrome (non-neurogenic neurogenic bladder), lazy bladder syndrome, spina bifida, reduced mental status, benign obstructing mass, locally invasive mass, posterior urethral valves, prune belly syndrome

GENETICS
Genes related to underlying etiology

PATHOPHYSIOLOGY
- Obstipation
  - Surgery, narcotic use, immobility, urinary tract infection (bacterial or viral), local inflammation (balanitis, meatal stenosis, labial adhesions, cellulitis), constipation, incarcerated inguinal hernia, acute neurologic inflammatory processes, invasive mass, drug related
- Neurogenic bladder
- Inflammation/infection
  - Effect on brain/meninges (encephalitis, meningitis, Guillain–Barre syndrome, encephalitis
  - Neurologic inflammatory disorders: Transverse myelitis, Guillain–Barre syndrome, encephalitis
  - Neurologic neoplasms: neuroblastoma, ependymoma, Ewing sarcoma
  - Benign neurologic abnormalities: Tethered cord

ASSOCIATED CONDITIONS
- Dysfunctional elimination syndrome
- Neurogenic bladder
- Inflammation/infection
  - Effect on brain/meninges (encephalitis, meningitis, Guillain–Barre syndrome, encephalitis
  - Neurologic inflammatory disorders: Transverse myelitis, Guillain–Barre syndrome, encephalitis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
- Urine culture
- Bacterial infection
- Cytomegalovirus (CMV)
- Epstein Barr Virus (EBV)
- Isosporic cysts
- Prostatitis
- Adverse drug effect
- Neurogenic dysreflexia
- Neurogenic bladder
- Cystitis (bacterial or viral) (2)
- Bacterial
  - Gram positive
  - Gram negative
- Viral
  - Neoplastic virus (HSV)
  - Varicella Zoster virus (VZV)
  - Cytomegalovirus (CMV)
  - Epstein Barr Virus (EBV)

DIFFERENTIAL DIAGNOSIS
- Tumor
- Adverse drug effect
- Neurogenic dysreflexia
- Neurogenic bladder
- Myelodysplasia
- Sacrococcygeal teratoma
- Prune belly syndrome
- Tethered spinal cord
- Detrusor sphincter dyssynergia
- Other
  - Constipation
  - Adverse drug effect
  - Trauma
  - Electrolyte abnormalities (hypermagnesemia) (1)
TREATMENT

GENERAL MEASURES
- Empty bladder with catheter
- Initiate clean intermittent catheterization until resolution.
- Complete workup based upon findings on history and physical exam.
- For chronic retention, after complete workup to rule out pathologic cause, begin behavioral modification (increase water intake, increasing voiding attempts to every 3 h, treat constipation)

MEDICATION
First Line
- Polyethylene Glycol 3350 for constipation/dysfunctional elimination syndrome – 0.5–1.5 g/kg daily, max. dose 17 g/d.
  - Use only in children older than 6 mo

Second Line
- α-Blockers (3,4)
  - Smooth muscle relaxation and decreased bladder outlet resistance:
    - Doxazosin <6 yr 0.5 mg daily
    - Doxazosin >6 yr 1 mg daily
- Steroids for inflammatory processes (2)
  - Very seldom used. Stress dose steroids.

SURGERY/OTHER PROCEDURES
- In acute setting, place urethral catheter
- If unable to place catheter, place suprapubic cystostomy tube.
- For posterior urethral valves, perform cystoscopy, transurethral incision of valves.
- For urethral stones, cystoscopy and laser lithotripsy or basket extraction (may require antegrade and retrograde approach).
- For obstructing fibroepithelial polyp, transurethral resection possible, vs. open cystotomy and excision.
- For obstructing prolapsing ureterocele, incision of ureterocele may leave obstructing tissue. May require resection of ureteroureterostomy or bladder neck reconstruction.
- Urthral stricture—based on length
- For significant detrusor sphincter dyssynergia, may benefit from bladder wash injection into urethral sphincter vs. urethral dilatation

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Behavioral modification
  - Timed voiding
  - Increased water intake
  - Pelvic floor relaxation

Complementary & Alternative Therapies
Biofeedback program for dysfunctional elimination syndrome

ONGOING CARE

PROGNOSIS
Based upon etiology.

COMPLICATIONS
- Bladder rupture in acute urinary retention; usually associated with trauma
- Postobstructive diuresis after relief of acute retention
- Urinary tract infection from stasis of chronic retention
- Chronic retention with high detrusor pressure can lead to renal impairment
- Misdiagnosis of malignant cause of urinary retention

FOLLOW-UP
Patient Monitoring
- Monitor for post-obstructive diuresis after drainage.
- May require fluid replacement in neonates

Patient Resources

CODES
ICD9
- 596.0 Bladder neck obstruction
- 999.0 Urinary tract infection, site not specified
- 798.20 Retention of urine, unspecified

ICD10
- N32.0 Bladder-neck obstruction
- N39.0 Urinary tract infection, site not specified
- R33.9 Retention of urine, unspecified

CLINICAL/SURGICAL PEARLS
- Urinary retention in a newborn must be closely evaluated with RBUS and VCUG to rule out posterior urethral valves, ureteroceles, and urethral strictures.
- Young boys presenting with acute urinary retention should undergo DRE to rule out prostatic or bladder neck obstruction.
**URINARY TRACT INFECTION (UTI), ADULT FEMALE**
Duane R. Hickling, MD
Victor W. Nitti, MD, FACS

### BASICS

**DESCRIPTION**
- Urinary tract infection (UTI) in a female is defined as a symptomatic urothelial inflammation secondary to bacterial adhesion and internalization within the urinary tract.
- Most common human bacterial infection.
- Tremendous economic impact.
- $3.5 Billion annually in the United States.
- Possibility of progression to urosepsis.

**Prevalence**
- 58,067 cases per 100,000 adult women (1)
- 44% have at least 1 rUTI in 12 mo
- 13,320 cases per 100,000 adult women/yr (1)
- Complicated: Structural or functional abnormality, or anatomical: Lower (confined to bladder and/or urethra) vs. upper (involving the ureters and/or kidneys).

### EPIDEMOLOGY

#### Incidence
- 13,320 cases per 100,000 adult women (1)
- 44% have at least 1 UTI in 12 mo
- 5% more than 3 UTIs in 12 mo

#### Bacteriology of female UTI (1):
- Antibiotic: Escherichia coli (74.2%), Klebsiella pneumonia (6.2%), Enterococcus sp (5.3%), Streptococcus pyogenes (3.9%), Proteus mirabilis (2.0%), and Staphylococcus saprophyticus (1.4%).
- Nosocomial: E. coli (65.5%), Enterococcus species (8.6%), K. pneumonia (8.0%), E. aeruginosa (8.3%), P. mirabilis (2.2%), Pseudomonas aeruginosa (1.8%).
- Nursing home: E. coli (86%), Enterococcus species (11.1%), Proteus mirabilis (10.1%), K. pneumonia (9.7%), Pseudomonas aeruginosa (3.2%).

#### Prevalence
- 53,067 cases per 100,000 adult women (1)

### RISK FACTORS

#### Behavioral factors
- Sexual intercourse, spermicide use, barrier contraceptive, recent antibiotic use, dysfunctional voiding

#### Anatomic variations
- Perineal and urogenital anatomy is thought to be important only in absence of other risk factors
- Urinary tract obstruction: Medullary sponge kidney, calyceal diverticula, ureteral obstruction, ureterocele; junction obstruction, vesicoureteral reflux, primary bladder neck, urethral stricture, or benign prostatic hyperplasia

#### Physiologic factors
- Diabetes mellitus
- Obstetric history
- Pregnancy
- Anatomic or functional abnormalities of the urinary tract

### GENERAL PREVENTION

- Avoidance of spermicides and barrier contraceptives
- Although hygiene, pericoital voiding, hydration has not been shown to be uniformly effective in UTI prevention women are encouraged to clean perineum wiping from back to front and should empty bladder before, and after intercourse.

### DIAGNOSIS

#### HISTORY
- UTI signs/symptoms: General malaise, frequency, urgency, urge incontinence, dysuria, suprapubic pain, pelvic pain, cloudy urine, foul smelling urine, hematuria
- Pyelonephritis: Fever, chills, flank pain
- Nephrogenic: Vascular, renal failure
- Neurologic: Dizziness, confusion
- Gastrointestinal: Nausea, vomiting, diarrhea
- Dermatologic: Pruritus, rash
- Obstetric: Abnormal vaginal discharge, pelvic pain, vaginal discharge
- Immunocompromised: Widened differential diagnosis

#### PHYSICAL EXAM
- Vital signs: Hemodynamic instability can be associated with pyelonephritis/urosepsis
- Gynecologic: Menstrual cycle, birth control, menopausal status, STI/STD’s, pelvic organ prolapse
- Neurologic: Dizziness, confusion
- Dermatologic: Pruritus, rash
- Obstetric: Abnormal vaginal discharge, pelvic pain, vaginal discharge
- Immunocompromised: Widened differential diagnosis

#### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab
- Urinalysis: Leukocyte esterase, Sensitivity 68–99%
- Specificity 98–96%
- Positive predictive value 19–86%
- Negative predictive value 91–97%
- Nitrite: Sensitivity 19–45%
- Specificity 95–98%
- Positive predictive value 50–78%
- Negative predictive value 62–89%
- Diabetes mellitus
- Unilateral or symmetric abnormalities of the urinary tract

#### Associated conditions
- Pregnancy
- Diabetic mellitus
- Unilateral or symmetric abnormalities of the urinary tract

#### TREATMENT
- Empiric antibiotics: Ciprofloxacin, nitrofurantoin, trimethoprim-sulfamethoxazole
- Empiric antibiotic selection based on local resistance patterns
- Discontinue empirical antibiotics if negative urine cultures
- Complete UTI treatment:
  - Most severe infections: Hospitalization, antibiotics, Foley catheter
  - Not severe infections: Oral antibiotics
- Discontinue antibiotic prophylaxis if symptomatic freedom is achieved

#### ASSOCIATED CONDITIONS

- Pregnancy
- Diabetic mellitus
- Unilateral or symmetric abnormalities of the urinary tract
URINARY TRACT INFECTION (UTI), ADULT FEMALE

- Leukocyte esterase and nitrite
  - Sensitivity 35–46%
  - Specificity 98–100%
  - Positive predictive value 89%
  - Negative predictive value 98%
- Microscopy
  - Urinalysis: 3–5 million cells/mL
  - 100 red blood cells/mL
- Bacterial culture
  - Sensitivity 80–90%
  - Culture organisms: 105 cfu/mL
- Antimicrobial susceptibility testing
- Leukocyte esterase
- Nitrite
- C-reactive protein
- Ultrasound
- Imaging
- Generally unnecessary; obtain if suspect pyelonephritis
- Indications: persistent fever (72 h after initiation of treatment), suspected urolithiasis (urine pH <6.0, history of calculus, very severe flank pain), unexplained persistent hematuria, bacterial persistence, acute/chronic urinary tract infection with fever
- First-line: renal ultrasound
- CT: if pyelonephritis; further evaluation or other imaging

DIAGNOSTIC PROCEDURES/SURGERY
- Cystoscopy: generalized erythema and edema of bladder
- Imaging: generally unnecessary; obtain if suspect complicated UTI
- Indications: persistent fever (72 h after initiation of treatment), suspected urolithiasis (urine pH <6.0, history of calculus, very severe flank pain), unexplained persistent hematuria, bacterial persistence, acute/chronic urinary tract infection with fever
- First-line: renal ultrasound
- CT: if pyelonephritis; further evaluation or other imaging

SURGERY/OTHER PROCEDURES
- Rarely indicated unless the following present:
  - Obstruction and uropathies: Stent or percutaneous nephrostomy tube (PNT)
  - Renal access drainage: Percutaneous drainage
  - Urethral diverticulum
  - Emphysematous pyelonephritis

ADDITIONAL TREATMENT
- Radiation Therapy
  - N/A

ADDITIONAL THERAPIES
- Complementary & Alternative Therapies
  - Cranberry extract: Hydrolyzed to ammonia and emphysematous pyelonephritis: Drainage or nephrostomy

CLINICAL/SURGICAL PEARLS
- Always consider urolithiasis with UTI when flank pain is severe.

REFERENCES

ADDITIONAL READING
**URINARY TRACT INFECTION (UTI), ADULT MALE**

Patricia Lewandoski, MD  
Akhil Das, MD, FACS

**BASICS**

- **DESCRIPTION**
  - A urinary tract infection (UTI) is a male is an inflammatory response of urothelium to bacterial invasion with associated bacteriuria and pyuria (1).
  - Defined by source of infection:
    - Cystic: Infection of bladder; dysuria, frequency, urgency, suprapubic pain, hematuria.
    - Isolated cysts in men rare, usually associated with prostatitis or pyelonephritis.
    - Pyelonephritis: Infection of kidney, chills, fever, flank pain is symptoms of cystitis.
    - Prostatitis infection or inflammation of prostate; acute or chronic; either bacterial or nonbacterial based on NIH Classification (see Section I: “Prostatitis, General”).
  - Urethritis: Infection of urethra
  - Defined as uncomplicated or complicated
    - Uncomplicated: Isolated infection or reinfecion in a healthy young male with normal urinary tract; urethral or prostatic.
    - Complicated: Infection associated with:
      - Structurally abnormal urinary tract (eg, bladder outlet obstruction/PROLIF), or
      - Functionally abnormal urinary tract (eg, neurogenic bladder)
      - Injured/host defense (eg, immunosuppression/diabetes)
      - Increased bacterial virulence
    - Most UTIs in men are complicated.
  - Defined based on chronicity:
    - Recurrent: UTI that has not responded to antimicrobial treatment.
    - Recurrent: UTI that occurs after complete resolution (proven by negative culture after complete antimicrobial course) of previous UTI.
  - Risk factors of UTI:
    - History of childhood UTI
    - History of adolescence UTI
    - Recent antimicrobial use
    - Previous UTI
    - Male gender
    - Diseases: Diabetes mellitus; recent UTI, urinary tract obstruction (eg, BPH, urethral stricture disease); urinary stasis
    - Immunosuppressive disease or diseases requiring immunosuppressive therapy
  - **EPIDEMIOLOGY**
    - **Prevalence**
    - Incidence 12.8/100 person years if prostatitis included as UTI (1)
    - Infections may increase with age to > 10% in men aged 85 yrs.
    - Asymptomatic bacteriuria in elderly men approaches 80%. (2)
  - **RISK FACTORS**
    - Risk factors for complicated UTI:
      - Male gender
      - Diabetes: Diabetes mellitus; recent UTI
      - Immunosuppressive disease or diseases requiring immunosuppressive therapy such as steroids
      - Recent antimicrobial use
      - Involuntary urinary catheter
      - Recent urologic intervention or hospitalization
      - Urethral tract obstruction (eg, BPH, urethral stricture disease); urinary stasis
        - Urinary calculi
        - Hematuria
        - Porous cirrhotic prostate
        - History of childhood UTI
  - **GENETICS**
    - Certain individuals (including those with HLA-A3) more prone to recurrent UTIs have increased epithelial cell receptivity for uropathogenic Escherichia coli.
  - **PATHOPHYSIOLOGY**
    - UTI occurs via 1 of 3 routes (1):
      - Ascending:Via inoculation of urethra/urethral catheter with bowel flora
      - Bladder: Host recognition of bacteria, with innate host defense mechanisms and bacterial virulence:
        - Inherent host defense mechanisms
          - Urinary flora helps denature extracellular infection; conversely, residual urine/bacterial density increases risk of infection
        - Virulence: Urine, pH, organic acids help prevent growth; glucuronic acid provides environment conducive for bacterial growth and increases risk of infection
      - Hemorrhages: Host recognition of bacteria, with innate immune response against infection; exfoliation of infected urothelial cells
      - Infection of urinary tract involves attachment of bacterium to host’s epithelium
        - Adherence of bacteria to urothelial cells necessary for infection; some virulent bacteria have type 1 pili (mediating attachment to cells); pyelonephritis bacteria contain F pilus
      - Common community acquired uropathogens: E. coli (most common), Proteus, Klebsiella pneumoniae, Providencia rettgeri, Staphylococcus epidermidis
      - Common nosocomial uropathogens: E. coli, Klebsiella, Enterobacter, Citrobacter, Proteus, Providencia, S. epidermidis
      - Associated conditions:
        - “Risk Factors”
      - **DIAGNOSIS**
        - **Lab**
          - **Urinalysis:** Qualitative tests of specimen already assessed by presence (p30) or absence (p30) of squamous cells.
          - **Microscopic analysis:** Bacteria: False positive from foreskin contamination if poor-quality specimen; false negative 10^7–10^9 bacteria/mL (too few to be seen under slide).
          - **Urethral swab:** WBC must be present for infection but false negative if 10^7–10^9 bacteria/mL (too few to be seen under slide).
          - **Urinary tract infection (UTI):**
            - **WBC:** Bacterial reduction of nitrate in urine
            - **Nitrite:** Presence of WBC
            - **Leukocyte esterase:** Presence of WBC
            - **Low-grade bacterial infection:** Positivity varies greatly; does not replace microscopic analysis for bacteria.
          - **Culture:** Minimum clean catch. Reduce bacterial contamination of culture in uncircumcised men by retracting foreskin and cleansing.
          - **Sensitivity:** Uptake of 10^7–10^9 bacteria/mL.
          - **Specificity:** Sensitivity of nitrite and leukocyte esterase positivity varies greatly; does not replace microscopic analysis for bacteria.
        - **Imaging**
          - Recommended in most men to rule out complicated infection, if not responding to therapy, in patients with rapid recurrent infection and found to have bacteria susceptible to antimicrobial used (i.e., resistant), when obstruction suspected.
          - **CT urogram or MRI:** Provide excellent detail, evidence of urinary tract abnormalities, stones, or foreign bodies, among others.
        - **Diagnosis Procedure/Surgery**
          - **Cystoscopy:** Same indications as stated under “Imaging,” allows direct visualization of bladder to assess for foreign body, ectopic ureters, diverticula, stones, or other abnormalities.
          - **IVU:** Should be considered in men with BPH, voiding dysfunction, high residual with stasis increases risk of infection.
        - **Localization studies:** Selective drainage from each infected site.
          - **Selective cultures from each infected site:**
          - **Localization studies:** Selective drainage from each infected site.
          - **Selective cultures from each infected site:**
          - **Localization studies:** Selective drainage from each infected site.
  - **PHYSICAL EXAM**
    - Assess for any of risk factors listed above.
    - Workup of recurrent UTI, inquire about risk factors and obtain a complete and thorough culture history of involved bacteria, treatment course, and documented evidence of clearance of bacteria.
  - **DIAGNOSTIC TESTS & INTERPRETATION**
    - **Culture:** Minimum clean catch. Reduce bacterial contamination of culture in uncircumcised men by retracting foreskin and cleansing.
    - **Sensitivity:** Uptake of 10^7–10^9 bacteria/mL.
    - **Specificity:** Sensitivity of nitrite and leukocyte esterase positivity varies greatly; does not replace microscopic analysis for bacteria.
    - **Culture:** Minimum clean catch. Reduce bacterial contamination of culture in uncircumcised men by retracting foreskin and cleansing.

**GENERAL PREVENTION**

Maintenance of low residual urine, cleaning any foreign bodies (catheters, stones).

---

**REFERENCES**

DIFFERENTIAL DIAGNOSIS

- Urinary, frequency, dribbling, and dysuria can be symptoms of prostatitis.
- Prostatitis:
  - NH Class I: Acute bacterial prostatitis, sudden onset.
  - NH Class II: Chronic bacterial prostatitis, insidious onset, relapsing, recurrent UTI
- For cystitis: Interstitial cystitis vs. urethritis
- For pyelonephritis: Papillitis vs. appendicitis vs. diverticulitis vs. acute focal/multifocal nephritis

TREATMENT

GENERAL MEASURES

- Maintain adequate hydration and hygiene.
- Remove urinary catheters as soon as possible to prevent catheter-associated UTI

MEDICATION

First Line

- Antimicrobial therapy for UTI in men is extrapolated from data for treatment of women. (see Section II: "Prostatitis, General")
- If fever or infection is present, CT should be obtained to rule out obstructive pyelonephritis; if found, decompression is critical.
- Common oral antimicrobials (1):
  - Trimethoprim-sulfamethoxazole: Inexpensive, covers staphylococci, streptococci, and most gram-negatives except Pseudomonas
  - Fluoroquinolones: More expensive (levofloxacin > ofloxacin), cover staphylococci and most gram-negatives (including Pseudomonas)
- Common parenteral antimicrobials:
  - Ampicillin: Covers streptococci, enterococci, E. coli. Probenecid addition of p-lactamase inhibitor covers Klebsiella and haemophilus; no pseudomonal coverage; good 1st-line antibiotic.

For cystitis (1)

- Trimethoprim-sulfamethoxazole: Ineffective, covers staphylococci, streptococci, and most gram-negatives except Pseudomonas
- Fluoroquinolones: More expensive (levofloxacin > ofloxacin), cover staphylococci and most gram-negatives (including Pseudomonas)
- Common parenteral antimicrobials:
  - Gentamicin: Staphylococci, most gram-negatives; good 1st-line IV drug coverage in pyelonephritis
- Ampicillin: Covers streptococci, enterococci, E. coli. Probenecid addition of p-lactamase inhibitor covers Klebsiella and haemophilus; no pseudomonal coverage; good 1st-line antibiotic.

For prostatitis (1)

- Take into account local resistances
- No controlled trials; antimicrobials based on local resistances, previous culture
- Further tailored to culture sensitivities
- Duration: For most men with complicated infections, treat for at least 10 days
  - In complicated UTI, obtain culture during therapy and 1–2 wk after therapy is complete to document clearance.
- For uncomplicated UTI, longer duration treatment (>7 days) has no association with a reduced risk for early or late recurrence compared to shorter treatment (≤7 days)

- Trimethoprim-sulfamethoxazole (14 days)
- Fluoroquinolones (14 days)
- For men, pyelonephritis is a complicated UTI and outpatient therapy is initiated only after treatment of complicating factors is initiated.

For pyelonephritis (1)

- For men, pyelonephritis is a complicated UTI and outpatient therapy is initiated only after treatment of complicating factors is initiated.
- Renal/pelvi-perineal abscess: Suspected if renal/intrarenal fever >72 h and/or persistently positive urine culture despite therapy, CT when suspect, if small abscess antimicrobial treatment; if large (>3 cm) abscess or pyelonephritis abscess, percutaneous drainage

- Outpatient therapy:
  - Fluoroquinolones (7 days) is more effective than trimethoprim-sulfamethoxazole (14 days)
  - Tailor antimicrobial to culture sensitivities
  - If no improvement, use IV therapy

- Initial therapy:
  - IV fluoroquinolone or ampicillin + gentamicin or 3rd generation cephalosporin
  - Duration without bacteremia: 2–3 days IV then 10–14 days PO antimicrobial
  - Duration with bacteremia: 7 days IV then 10–14 days appropriate PO antimicrobial

- Repeat cultures on therapy and 10–14 days after completion of course should be negative; if positive, continue a 14 day specific regimen

SECOND LINE

- Abscesses in the upper urinary tract or prostate often require percutaneous drainage.

SURGERY/OTHER PROCEDURES

- As needed for cause of recurrent UTI, such as stone, foreign body, or enlarged prostate.
- Transurethral resection (TUR) (unroofing procedure) or percutaneous drain may be required for prostatic abscess.

ADDITIONAL TREATMENT

Radiation Therapy

- N/A

Additional Therapies

- N/A

Complementary & Alternative Therapies

- Cranberry juice: No male evidence (4)

ONGOING CARE

PROGNOSIS

When appropriate antimicrobial therapy is chosen, complicating factors are identified and treated, and close follow-up is achieved with documentation of clearance of infection, a good prognosis is expected.

COMPLICATIONS

- Sepsis
  - Upper urinary tract infections with abscess formation can cause loss of renal function.

FOLLOW-UP

Patient Monitoring

- Follow-up culture, post void residual urine (PVR) and decompression.

Patient Resources

CODES

ICD9

- 595.80 Pyelonephritis, unspecified
- 595.9 Cystitis, unspecified
- 596.5 Urinary tract infection, site not specified

ICD10

- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N29.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Most UTIs in men are considered complicated and require a longer course of antibiotics.
- UTI-related prostatitis requires a minimal of 7 days of treatment.
URINARY TRACT INFECTION (UTI), CATHETER-ASSOCIATED (CAUTI, CA-UTI)

Jeremy N. Reese, MD, MPH
Timothy D. Averch, MD, FACS

BASICS

DESCRIPTION
- Catheter-associated urinary tract infection (CAUTI) (CA-UTI) is defined as an infection occurring in a person whose urinary tract is currently catheterized or has been catheterized within the previous 48 h.
- May refer to indwelling urethral or suprapubic catheters as well as routine intermittent catheter use.
- Catheter-associated asymptomatic bacteriuria (CA-ASB) is the presence of bacteria in the urinary tract without signs or symptoms of infection.
- CA-UTI and CA-ASB are often not distinguished from each other in reported cases of catheter associated bacteriuria and may result in inappropriate antibiotic use contributing to antimicrobial resistance and adverse event reporting to governmental agencies.
- UTIs are the most common type of healthcare-associated infection reported to the National Healthcare Safety Network (NHSN).

EPIDEMOLOGY

Incidence
- CA-UTI is the most common nosocomial infection in the United States, accounting for 40% of hospital-acquired infections and over 80% of the 900,000 cases of bacteriuria annually.
- 15–25% of hospitalized patients have a urethral catheter inserted during their stay.
- Incidence of CA-bacteriuria is thought to be 3–8% per catheter-day, with 3–7.4 CA-UTIs per 1000 urinary catheter days reported in US intensive care units.
- Cost: $1006 per episode of CA-UTI

Prevalence
- 5–10% of long-term care facility patients are managed with indwelling or intermittent catheterization, accounting for >100,000 patients in the United States at any given time.

RISK FACTORS

Duration of catheter use, placement outside operating room, open drainage system, female sex, diabetes mellitus, renal insufficiency, and inappropriate use (discussed below)

Genetics
- N/A

PATHOPHYSIOLOGY

- Urinary catheterization is most important predisposing factor for nosocomial UTI
- Disrupted mucosa exposes new binding sites for bacteria allowing for growth of less virulent organisms
- Indwelling catheter may introduce bacteria at time of insertion, allowing ascension of uropathogens into bladder at time of insertion and then via intra- and extra-luminal spread
- 2/3 of identified pathogens are extrinsically acquired vs. 1/3 intrinsically acquired

- Bacterial adhesions and production of exopolysaccharides allow for replication on the catheter surface and formation of biofilms
- Short-term catheter use tends to be associated with a single organism, whereas longer catheter use is associated with polymicrobial growth
- Biofilms protect bacteria from antimicrobials and host immune response, facilitating spread of antimicrobial resistance genes
- Enterococci is most common isolate, as well as Klebsiella, Enterococcus, Enterobacter, Proteus, Pseudomonas, Streptococcus, and Enterococcus
- Providencia, Morganella, and Proteus species are more commonly isolated from long-term catheters

ASSOCIATED CONDITIONS

Spinal cord injury, neurogenic bladder, urinary incontinence, scar or perineal wounds, prolonged immobilization

GENERAL PREVENTION

- Limiting use of urinary catheters, aseptic insertion, early discontinuation of catheter use, use of pre-sealed closed drainage systems, maintaining drainage bag below level of bladder (1A)
- Absolute indications include urinary retention, accurate measurement of urine output in critically ill patients, prolonged general or spinal anesthetic, following selected urologic or gynecologic procedures, comfort care
- Application of institutional reminders such as nurse or electronic-based reminders, automatic stop-orders, use of reminder stickers or dated collection bags, requirement of physician order to place and maintain catheters
- No trials support use of: antimicrobial or chemical prophylaxis, routine catheter irrigation, antimicrobial use in drainage bag, antibiotic use at time of routine catheter exchange or removal
- Routine screening for CA-ASB should be avoided (1A)
- Alternatives to indwelling urethral catheters
- Condom catheters provide alternative to short-term catheter use in men with low-post void residuals
- Urethral and suprapubic catheters have similar rates of CA-UTI, although suprapubic catheters are often more comfortable, spare urethral catheterization, and are easier to exchange
- Intermittent catheterization significantly reduces rates of CA-ASB and is associated with higher patient satisfaction

- Healthcare providers should clean their hands with soap and water or use an alcohol-based hand rub before and after touching catheters.
- Avoid disconnecting the catheter and drain tube.
- The catheter is secured to the leg to prevent pulling on the catheter.
- Keep the bag lower than the bladder to prevent urine from backflowing to the bladder.
- Empty the bag regularly, the drainage spout should not touch anything while emptying the bag.

DIAGNOSIS

HISTORY
- CA-UTI: Patients with signs and symptoms of UTI with current or recent (<48 h) indwelling urinary catheter or routine intermittent catheter use
- Symptoms may include dysuria, urgency, altered mental status, malaise, flank pain, and pelvic discomfort
- Patients with a recently removed catheter may report dysuria, urinary urgency and/or frequency
- Spinal cord injury patients may report increased spasticity, autonomic dysreflexia and/or sense of uneasiness

PHYSICAL EXAM
- A few physical exam findings are reliable to diagnose CA-UTI but may include suprapubic and/or costovertebral angle tenderness, hematuria, or fever
- Foul-smelling and/or cloudy urine have not been shown to be significant clinical predictors of CA-UTI
- Encourage hydration if no other clinical indicators of infection and reassess thereafter

DIAGNOSTIC TESTS & INTERPRETATION

- CA-UTI: Patients with signs and symptoms of UTI with current or recent (<48 h) indwelling urinary catheter or routine intermittent catheter use with cultures growing >103 cfu/mL (1A)
- CA-ASB is defined as cultures growing >105 cfu/mL (1A)
- Urine specimens should be sent for culture prior to initiation of antimicrobials (1A)
- Catheters should be replaced, if still indicated, and a culture should be obtained from newly placed catheter (1A)
- If catheter can be discontinued, a midstream voided specimen should be used for culture (1A)
- Pyuria on urinalysis is not sufficient to diagnose CA-UTI or CA-ASB, but its absence can exclude infection (1A)

Imaging
- Not routinely indicated
- May be necessary in cases of suspected complicated UTI such as concern for urinithiasis, foreign body, abscess, emphysematous infection, or vesicoureteral reflux

Diagnostic Procedures/Surgery
- Not routinely indicated
- Unidiagnostic studies may be useful to determine necessity of routine catheterization, particularly in spinal cord injury (SCI) population
- For patients with long-term catheter use (eg, SCI, neurogenic bladder population), routine cystoscopy has been suggested for cancer detection due to increased risk of both transitional cell and squamous-cell carcinomas
- Lifetime bladder malignancy incidence ranges from 0.39% to 2.24% in published retrospective reviews of SCI patients

Pathologic Findings
- Pathology is not routinely performed
Differential Diagnosis

- In patients presenting with fever, chills, altered mental status, and other non-specific symptoms, all other sources of infection must be ruled out as CA-ASB is diagnosed in >95% of patients with long-term catheter use
- Bladder tumor: Hematuria must be worked up, given increased risk of malignancy from long-term catheter use
- Bladder calculus: Associated with chronic urinary stasis
- Local inflammation: Vaginitis, urethritis, interstitial cystitis

Treatment

General Measures

- Prevention through early removal of urinary catheters is best preventative treatment
- Routine screening for and treatment of CA-ASB should be avoided
- Optimal duration of therapy is unknown, but typically ranges from 3 to 21 days depending on severity of symptoms (e.g., cystitis, pylephritis, associated abscess, or bacteremia)

- Most literature suggests 7–14 days of therapy for CA-UTI
- 3-day regimen suggested in younger women (< 65 y) in whom a catheter was recently removed
- Catheters placed > 2 wk prior should be exchanged at time of diagnosis (prior to cultures being sent) to improve antimicrobial penetration and reduce bacterial sensitivity
- When possible, antibiotic therapy should be culture driven to avoid exposure to additional antimicrobial agents

Medication

First Line (2,3)

- Given incidence of polymicrobial colonization as well as involvement of both gram-positive and -negative organisms, no 1st-line agent can be recommended
- Serious infections must be covered with broad-spectrum antibiotics and narrowed based on bacterial sensitivities
- Treatment of minor infections should be delayed until culture sensitivities are available to guide antimicrobial selection

Second Line

- N/A

Surgery/Other Procedures

- Filled indicated, but may be necessary in cases of encrusted catheters, emphysematous or abscess forming infections (see Section I. UTI, complex, adult)

Additional Treatment

Radiation Therapy

- N/A

Additional Therapies

- Complementary & Alternative Therapies
- Antimicrobial coated catheters may delay detection of CA-ASB in short-term catheter use (<1 wk)
- Mercurineux salts may reduce CA-ASB and CA-UTI in short-term catheter use (<1 wk)
- Cranberry products have not been shown to be effective in the prevention or treatment of infection in CA-UTI population

Ongoing Care

Prognosis

- Generally good
- Patient hospitalization lengths and costs are elevated when diagnosed with CA-ASB or CA-UTI
- Mortality rate among hospitalized patients with bacteremic UTI is < 1%, however, > 1% of CA-ASB results in bacteremia

Complications

- Patients with indwelling catheter experience increased rates of bacteremia, upper tract infection, catheter obstruction, urinary stone formation, fistula formation, urethral erosion, incontinence, and bladder cancer

Follow-Up

- Patient Monitoring
- Institutional education on indications for catheter use and reminder systems for early catheter removal such as nursing protocols, electronic reminders, chart and collection bag stickers
- Attention to staff education to urologically essential care

- Patient Resources
- Medline Plus: Catheter Related UTI
- Website: http://www.nlm.nih.gov/medlineplus/ency/article/000483.htm

Codes

ICD-10

- G44.49 Other and unspecified Escherichia coli
- G98.0 Urinary tract infection, site not specified
- J09.64 Infection and inflammatory reaction due to indwelling urinary catheter

ICD10

- B96.20 Urinary catheter as the cause of disease, closed drainage
- N09.0 Urinary tract infection, site not specified
- T85.53XA Infective/Inflammatory reaction due to indwelling urinary catheter, intr

Clinical/Surgical Pearls

- Advise against routine screening for CA-ASB due to increasing antimicrobial resistance and inappropriate use
- Most important prevention is adherence to indications for catheter use and prompt removal when no longer indicated
- When catheter use is unavoidable, it should be aseptically inserted, maintained with closed drainage system and removed as early as possible
- When infection is suspected, culture specimen should be sent from a newly placed catheter or midstream voided specimen
- Treatment should be driven by culture sensitivities and typically last 7–14 days.
URINARY TRACT INFECTION (UTI), COMPLICATED, ADULT

Steve Dong, MD
Leonard G. Gomella, MD, FACS

PATHOPHYSIOLOGY

Primary UTI occurs via 1 of 3 routes (1):
- Ascending by inoculation of urethra/vesical catheter with bowel flora. Most common
- Hematogenous seeding of kidney
- Lymphatic spread
- Structural, functional, or metabolic abnormalities allow infection of more uncommon pathogens, and increase the rate of therapy failure
- E. coli, accounts for only approximately half of infections with complicated UTI, compared to uncomplicated (15–95%)
- A broader range of organisms can seen in complicated (ET), include Pneumococci, Klebsiella pneumoniae as well as Pseudomonas, Staphylococci, enterococci, staphylococci, and fungi (3)

ASSOCIATED CONDITIONS
- Diabetes mellitus (10%)
- Renal failure
- Multiple sclerosis
- Spinal cord injury

GENERAL PREVENTION

Proper infection control practice in health care facilities to avoid contact transfer of resistant organisms between patients.
- Patients with multiple sclerosis may present with fatigue or worsening neurologic function.
- Patients with spinal cord injuries can present with fever, pain, or placing a Foley catheter for urethral stricture.
- Patients with spinal cord injury, maintain a low bladder pressure to prevent reflux, ascending infections, and progression to renal failure.
- Monitoring of bladder pressure and function can be done with urodynamics testing.
- Prevention of complicated UTI with long-term prophylaxis in at-risk adult population is not recommended due to the emergence of resistant organisms (4)

DIAGNOSIS

HISTORY

Assess for any of risk factors listed above.
- Clinical presentation may or may not be associated with clinical symptoms (eg, dysuria, urgency, flank pain, fever)
- Clinical presentation may vary from severe obstructive polynephritis with imminent urosepsis to catheter associated UTI, which disappears once the catheter is removed.
- Patients with spinal cord injuries can present with bladder, leg spasms, or autonomic dysreflexia.
- Patients with multiple sclerosis may present with fatigue or worsening neurologic function.
- Fever without localized findings is a common presentation of UTI in patients with chronic indwelling catheters.

PHYSICAL EXAM

- Check vital signs to assess severity of infection, presence of systemic disease.
- Assess for suprapubic pain, flank pain, urethral discharge, renal exam for tenderness.
- Evaluate for anatomical abnormalities, such as the presence of a nephrostomy tube, or an renal conduit.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis
- Pyuria is almost always present
- Unless the collecting system is obstructed
- White cell casts suggest a renal origin
- Urine culture is positive for a UTI with the following:
  - ≥10^5 cfu/mL in mid-stream sample
  - ≥10^3 cfu/mL in a straight catheter urine sample

Imaging
- Is recommended in patients suspected of complicated infection, especially in those not responding to therapy for 48–72 h. In patients with rapid recurrent infection and found to have bacteria susceptible to antimicrobial used (eg, persistence), when obstruction suspected, as well as history of kidney stones or signs of renal colic.
- For patients who could not be exposed to radiation
- Cheaper and readily available
- Best to evaluate for hydronephrosis
- Lack details and sensitivities of other imaging modalities
- Computed tomography (CT) urogram
  - Most sensitive in detecting abnormalities and able to delineate extent of disease. Has 3 phases:
    - No contrast—evaluate for renal or ureteral calculi, gas-forming infections, hemorrhage
    - Contrast—detect areas lacking perfusion due to infection induced ischemia
    - Delayed phase—detect for any filling defects such as fungus ball
- Magnetic resonance imaging (MRI)
  - No advantage over CT except in patients who wants to avoid contrast and radiation (3)

Diagnostic Procedures/Surgery
- Urologic evaluation is often necessary in the setting of complex UTI
- Urinary obstruction associated with UTI must be relieved emergently, eg, placing a ureteral stent or nephrostomy tube for a obstructing ureteral calculus, or placing a Foley catheter for urethral stricture.
- Cystoscopy allows direct visualization of bladder to assess for foreign body, ectopic ureters, diverticula, stones, or other abnormalities that could be a nidus for infection.
TREATMENT

GENERAL MEASURES
If severe infection or toxicity is present, CT should be considered to rule out obstructive pyelonephritis; if found, decompression is critical.

DIFFERENTIAL DIAGNOSIS

• For cystitis: interstitial cystitis vs. urethritis.
• For pyelonephritis:
  – Pyelonephritis vs. appendicitis vs. diverticulitis vs. acute focal/multifocal interstitial nephritis – Urolithiasis

Medication

First Line

• Common oral antimicrobials:
  – Fluoroquinolones: More expensive (levoﬂoxacin > ciproﬂoxacin), cover staphylococci and most gram-negatives including Pseudomonas
  – Trimethoprim-sulfamethoxazole: Resistance is often seen, therefore not recommended for empiric therapy (3)
• Commonly parenteral antimicrobials:
  – For those who have hematologic instability, or cannot tolerate oral therapy, or for patients with suspected resistant organisms:
  – Gentamicin: Can cause Staphylococci, most gram-negatives including Pseudomonas
  – Augmentin for coverage in pyelonephritis – Cephalexin
  – Carbenicillin – Aminopenicillin PLUS a β-lactamase inhibitor: Amoxicillin by itself (eq, ampicillin) is not recommended for empiric therapy (3)
• For complicated pyelonephritis (1, 3)
  – Renal/renal pelvis abscess is suspected if indwelling catheter fever >37.8° and/or persistently positive culture despite antimicrobial treatment; CT when suspect; if small renal abscess, then antimicrobial treatment; if large (>3 cm) renal abscess or perinephric abscess, then percutaneous drainage
  – Inpatient therapy is recommended
• For cystitis: interstitial cystitis vs. urethritis.
 – Pseudomonas gram-negatives including Pseudomonas
  – Tigecycline: Has activity against ESBL bacteria, but is unstable in urinary tract.

SURGERY/OTHER PROCEDURES

As needed for cause of complicated UTI, such as stone, foreign body, or enlarged prostate.

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies

Cranberry juice and products have not been shown to reduce the risk of complicated UTI.

ONGOING CARE

PROGNOSIS

When appropriate antimicrobial therapy is chosen, complicating factors are identified and treated, and close follow-up is achieved with documentation of clearance of infection, a good prognosis is expected.

COMPLICATIONS

• More likely to occur in patients with comorbidities
• Acute complicated pyelonephritis can progress to emphysematous pyelonephritis, renal abscess, perinephric abscess, or papillary necrosis.
• Infections can spread to cause bone and joint infection, or endocarditis.
• Renal failure in patients with spinal cord injury with recurrent sepsis

FOLLOW-UP

Patient Monitoring
Repeat urine cultures must be obtained because patients with complicated UTI are more at risk for recurrent infection.

URINARY TRACT INFECTION (UTI), COMPLICATED, ADULT

ICD9
599.0 Urinary tract infection, site not specified
600.01 Hypertrophy (benign) of prostate with urinary obstruction and other lower urinary tract symptoms (LUTS)

ICD10
N29.0 Calculus of kidney
N40.1 Enlarged prostate with lower urinary tract symptoms (LUTS)
N59.0 Urinary tract infection, site not specified
N60.1 Enlarged prostate with lower urinary tract symptoms

CLINICAL/SURGICAL PEARLS

• Complicated UTI can have a wide range of atypical presentations, eg, MS patients with neurologic decompensation, spinal cord injury patients with symptoms of autonomic dysreflexia, or nursing home patient who has indwelling Foley with fever should be suspected of UTI.
• CT should be considered the imaging of choice, and with a low threshold with any history of stone, flank pain, or pyelonephritis not improving or persistent positive culture.
• Presence of obstruction on imaging requires urgent decompression.
URINARY TRACT INFECTION (UTI) COMPLICATED, PEDIATRIC

Christopher J. Long, MD
Douglas A. Canning, MD, FACS

PATHOPHYSIOLOGY
- Acute swelling of the pelvis allows ascending infection of the GU tract
- Bladder formation on stents or catheters
- Increased bladder pressure
  - Decreased bladder capacity
- Compromised Foley catheter drainage
- Dysfunctional voiding
- Bacteriology of E. coli increase affinity for GU tract: P fimbriae and MRHA (mannose-resistant hemagglutinin)

ASSOCIATED CONDITIONS
- Urinary stasis increases risk of UTI
- Stents or catheters located within the GU tract act as a nidus for bacterial colonization
- Surgically correctable conditions of the GU tract

GENERAL PREVENTION
- Antibiotic prophylaxis
  - Low-dose daily antibiotic
  - Healthy children have no proven benefit
- Consider circumcision in boys < 12 mo of age with GU tract anomalies
- Consider correction of vesicoureteral reflux (VUR) in females approaching puberty for increased risk of pyelonephritis during pregnancy
- Treatment of constipation and dysfunctional voiding

DIAGNOSIS
- History
  - Vague in infants and nonverbal children: Fever, irritability, poor feeding, vomiting, diarrhea
  - Older children: Dysuria, incontinence, voiding dysfunction, lower abdominal pain, enuresis
- Physical exam
  - Single-use, sterile catheters show no benefit
- Urinary stream, voiding history
- Presence and severity of fever
- Previous UTIs and how documented (urine analysis, culture, how culture was obtained)
- Previous GU/GI surgery
- Family history of infections and/or GU anomalies
- Prerenal history including ultrasound

ASSOCIATED CONDITIONS
- Family history of infections and/or GU anomalies
- Urinary stream, voiding history
- Presence and severity of fever
- Previous UTIs and how documented (urine analysis, culture, how culture was obtained)
- Previous GU/GI surgery
- Family history of infections and/or GU anomalies
- Prerenal history including ultrasound

LAB
- Blood work: CBC, BMP, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), procalcitonin
- Procalcitonin, CRP: ESR correlate with systemic illness and suggest pyelonephritis/sepsis
- Diagnosis: 2 or more symptoms, > 100,000 CFU/mL of a single organism, and > 10 WBC/HFP on urine microscopy
- Urinalysis (UA)
  - leukocyte esterase, nitrite
  - Microscopic: WBC, bacteria
- Urine culture: obtained with UA
  - Consider lower threshold (> 50,000 CFUs per mL)
  - PLUS yeasts: bacteria in some cases

IMAGING
- Renal and bladder ultrasound: Assess hydronephrosis or incomplete bladder emptying
- Voiding cystourethrogram if not already performed
- Consider Gallium scan for complicated cases
- Renal cortical scan: Rule out scarring or pyelonephritis
- Consider test of cure prior to study
- Renal cortical scan: Rule out scarring or pyelonephritis
- Renal cortical scan: Rule out scarring or pyelonephritis

DIAGNOSTIC PROCEDURES/SURGERY
- Catheterized or midstream specimen is preferred depending upon patient age
- Suprapubic aspiration has highest accuracy but increases morbidity for patients
- Bagged specimen not recommended
- Cystoscopy is rarely indicated
- Urine culture: obtained with UA

SPECIFIC INTERVENTION FOR GU ANOMALIES
- Consider treatment if reflux once therapy is completed

PATHOLOGIC FINDINGS
- Ziehl-Neelsen and/or Warthin-Starry stain
- Bacteria in the lower urinary tract
- Blood group antigen phenotype has been shown to increase risk of pyelonephritis

RISK FACTORS

TRIGGERS

GENETICS
- Polymorphisms of the interleukin-8 (IL-8) cytokine and decreased receptor expression increase risk for developing pyelonephritis
- Blood group antigen phenotype has been shown to play a role in UTI resistance

HISTORY
- Acute swelling of the pelvis allows ascending infection of the GU tract
- Bladder formation on stents or catheters
- Increased bladder pressure
  - Decreased bladder capacity
- Compromised Foley catheter drainage
- Dysfunctional voiding

- Increased bladder pressure
  - Decreased bladder capacity
- Compromised Foley catheter drainage
- Dysfunctional voiding
- Bacteriology of E. coli increase affinity for GU tract: P fimbriae and MRHA (mannose-resistant hemagglutinin)
Differential Diagnosis

- Younger children (<24 mo) presenting with fever, otitis media, gastroenteritis, upper respiratory tract infection
- Stone disease
- Urerovaginitis
- Dysfunction voiding/diuresis syndrome
- Pregnancy
- Appendicitis
- Bladder outlet obstruction
- Epipidymitis
- Abuse

Treatment

General Measures (2,3)

- Antibiotic therapy after urine culture obtained
- Oral antibiotic therapy vs. IV antibiotics dependent upon severity of infection
- Strive for absence of fever, concern for sepsis, elevated WBC, etc.
- Duration of therapy 7–14 days
- Increased rate of resistant organisms

Medication

First Line

- 3rd generation cephalosporin + aminoglycoside
  - Ceftriaxone: 100–150 mg/kg (q8–12h)
  - Ceftazidime: 100–150 mg/kg (q6–8h)
  - Aminoglycoside (gentamicin, tobramycin): 2.5 mg/kg (q8h)
- Combination therapy:
  - Aminoglycoside (gentamicin, tobramycin): 2.5 mg/kg (q8h)
  - Ceftazidime: 100–150 mg/kg (q6–8h)

Second Line

- Fluoroquinolones
  - Ciprofloxacin 40–90 mg/kg (q12–24h)
  - Levofloxacin 50–75 mg/kg (q24h)
  - Norfloxacin 90–150 mg/kg (q12h)

- 3rd- or 4th-generation cephalosporin

Surgery/Other Procedures

- Circumcision
- VUR
- Vesicoureteral Reflux

Surgical referral due to high risk

Follow-Up

- Document test of cure with repeat urine culture
- Patient should be examined

Additional Treatment

Radiation Therapy

- Myelosuppression

Additional Therapies (5)

- Topical therapy for voiding dysfunction
  - Timed voiding, biofeedback
  - Antibiotics for lower urinary tract infection
  - Poliectomy for detrusor sphincter dyssynergia

- Consider suppressive antibiotics in selected cases
  - Nitrofurantoin 1–2 mg/kg PO daily
  - Sulfamethoxazole/trimethoprim (SMZ-TMP)
  - 5–10 mg/kg SMZ, 1–2 mg/kg TMP PO daily (Do not use in infants or with sulfa allergy)
  - Trimethoprim 1–2 mg/kg PO daily
  - Ampicillin or amoxicillin not recommended due to resistance

Complementary & Alternative Therapies (4)

- Consider suppressive antibiotics in selected cases
- Fluoroquinolones
- 3rd- or 4th-generation cephalosporin
- Oral antibiotic therapy vs. IV antibiotics dependent upon severity of infection

- Abdominal pain
- Urinary tract infection
- Urinary tract infection
- Urinary tract infection
- Urinary tract infection

Ongoing Care

Prognosis

- Potential progression of infection

- Follow-up

- Document test of cure with repeat urine culture

- Consider nephrology referral

- Yearly blood pressure assessment

- Document test of cure with repeat urine culture

- Consider nephrology referral

Patient Resources

References

Additional Reading

Clinical/Surgical Pearls

- Complicated UTIs can lead to increased patient morbidity and mortality.
- Treatment plan should be tailored to the specific underlying contributing factors leading to UTI development.
- Prompt institution of broad spectrum antibiotics after urine culture is obtained with subsequent tailoring of antibiotic therapy based on bacteria sensitivities recommended in cases of recurrent or complicated UTIs.
- Maintain a high degree of suspicion for potentially surgically correctable causes. Correction will likely decrease UTI risk.
URINARY TRACT INFECTION (UTI), PEDIATRIC

Kathleen Kieran, MD, FAAP, FACS
Christopher S. Cooper, MD, FAAP, FACS

BASICS

DESCRIPTION
A urinary tract infection (UTI) represents inflammatory changes in the urinary tract caused by the presence of bacteria.

Spectrum of severity, from local infection to systemic changes/urosepsis.

EPIDEMIOLOGY
Incidence
• 180,000 children annually will develop UTI in the United States.
• 0.7% of all pediatric office visits each year (3.5–9% of emergency department visits).
• Overall 2% of febrile infants, 5% of all infants.
• 0.7% of all pediatric office visits each year (3.5–5% of emergency department visits).
• 0.7% of all pediatric office visits each year (3.5–5% of emergency department visits).
• 21% of uncircumcised male infants.
• 5% of female infants.
• 2–3% of circumcised male infants.

Prevalence
Prevalence is variable and closer to an adult level as age groups increase.

RISK FACTORS
• Previous UTI:
  – 100% of infants with a symptomatic UTI will have a recurrence.
  – Older females may have a 40–60% risk of recurrent infection.
• Immunosuppressive states, including diabetes, chemotherapy, and steroid use.
• Anatomic and functional abnormalities of the urinary tract which predispose to urinary stasis:
  – Vesicoureteral reflux, ureterocaliceal, ureteropelvic junction obstruction, bladder diverticula, posterior urethral valves.
  – Neurogenic bladder, dysfunctional voiding/elimination behaviors (e.g., constipation).
• Urologic instrumentation (catheters).
• Other children: Sexual activity.
• Circumcision (1):
  – Uncircumcised males, 1 yr of age have the highest rate of UTI of all gender and age groups (10 times higher than circumcision males).
  – AAP has stopped short of endorsing routine circumcision, but acknowledges apparent protective effect against UTIs and genital cancer.
• Consider circumcision in infant males with UTI.

GENERAL PREVENTION
• Identification and treatment of underlying urologic conditions which may predispose to urinary stasis.

GENETICS
• Incompletely understood.
• Multifactorial, including altered carbohydrate secretion antigens on cell surface molecules which may increase bacterial adherence.

PATHOPHYSIOLOGY
• Usually ascending infections, although hematogenous spread can be seen in infants or immunocompromised populations.
• Colonization of female introitus or male preputial epithelium with intestinal flora.
• The most common pathogen is Escherichia coli (85%–90%).
• Other uropathogens include Klebsiella, Proteus, Enterococcus, Citrobacter, Staphylococcus saprophyticus, and Enterococcus.

• Viral (e.g., adenovirus, BK virus) and fungal (Candida) infections may be seen in immunocompromised patients.
• Both humoral and cellular responses result in inflammation of the urinary tract.
• Bacterial virulence factors include O antigen (part of lipopolysaccharide), K antigen (part of capsule), and P fimbriae contributes to bacterial ascent to the upper tracts, even in the absence of reflux.

ASSOCIATED CONDITIONS
• Dysfunctional elimination including incontinence, holding or retention of urine, and constipation increase risk of UTI.
• Immunocompromise.
• Structural abnormalities of the GU tract.

GENERAL PREVENTION
• Good voiding/elimination habits.
• Treatment of constipation.
• Identification and treatment of underlying urologic conditions which may predispose to urinary stasis.

DIAGNOSIS

HISTORY
• Vague in infants:
• Older children may complain of dysuria, incontinence, changes in voiding habits, flank or abdominal pain, enuresis.
  – Presence, severity, and duration of fever.
• Previous UTIs and how documented (e.g., culture, urinalysis, symptoms).
• Prenatal history including prenatal ultrasounds.
• Other children: Sexual activity.
  – Circumcision (1):
    – Uncircumcised males, 1 yr of age have the highest rate of UTI of all gender and age groups (10 times higher than circumcision males).
    – AAP has stopped short of endorsing routine circumcision, but acknowledges apparent protective effect against UTIs and genital cancer.
• Consider circumcision in infant males with UTI.

PHYSICAL EXAM
• Specific findings in infants are rare; may see fever, failure to thrive, jaundice, or lethargy.
• Older children may have suprapubic, flank, abdominal and/or upper quadrant tenderness.
• PVF also raises concern for infection.
  – Cervical tenderness suggests pyelonephritis.
  – A sterile exam will help rule out epididymitis.
  – Caudal external genital exam to rule out trauma, local irritation, urethral discharge, phimosis, and anatomic abnormalities.
• Urine culture is the gold standard to diagnose UTI.
• Symptomatic bacteriuria (no symptoms, <5 WBC/hpf, but positive culture) should prompt treatment if a pathogenic organism is present.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
• Urine analysis (2):
  – Microscopic exam after dipstick urine analysis.
  – Also yields clues to contamination (epithelial cells).
• Positive leukocyte esterase (LE) indicates WBCs in the urine (up to 95% sensitive in children with symptoms.
• Positive nitrite (many gram-negative bacteria produce this substance) has a sensitivity of 30–45%, but a specificity that nears 100%.
• Positive leukocyte esterase (LE) indicates WBCs in the urine (up to 95% sensitive in children with symptoms.
• Positive nitrite (many gram-negative bacteria produce this substance) has a sensitivity of 30–45%, but a specificity that nears 100%.

• Combination positive nitrite-leukocyte esterase.
• Blood tests are unreliable in diagnosing UTI.
• Asymptomatic bacteriuria (no symptoms, <5 WBC/hpf, but positive culture) should prompt treatment if a pathogenic organism is present.

Imaging
• The need for and timing of imaging following UTI remains controversial.
• Imaging is not required in the acute setting, but may be indicated at follow-up.
• Consider evaluating all children ≤5 yr after their 1st documented UTI, and all girls, regardless of age, with febrile or recurrent infections, particularly with voiding dysfunction.
• Renal/Bladder US should be considered following a febrile UTI.
• Need for and timing of VCUG is controversial. The American Academy of Pediatrics (AAP) recommends VCUG after second febrile UTI unless there is a suspicion of underlying anatomic abnormality.
• 40% of children with a single febrile UTI have VUR.
• Absence of clinical improvement after 48 h of appropriate treatment should raise concern for structural or functional abnormalities.

Sedation may help to obtain a reliable renal ultrasound or VCUG.

In toilet-trained children in whom voiding dysfunction may be a factor, assessment or voiding patterns (e.g., stopwatch) may be helpful.
URINARY TRACT INFECTION (UTI), PEDIATRIC

Diagnosis/Procedures/Surgery
Nonspecific, though cystoscopy may be performed for associated conditions or chronic infections as indicated.

Pathologic Findings
- Cysts and polyps/implants are generally associated with inflammatory response.
- Renal scarring may be manifested by architectural changes including collagen deposition and glomerular loss.

Differential Diagnosis
- UTIs present similarly to other infections:
  - Bacteremia and sepsis
  - Urethritis
  - Pyelonephritis
  - Sexual abuse
  - Vaginitis
- Also consider: Appendicitis, diabetes, dysfunctional voiding/elimination, pregnancy in postpubertal females, urolithiasis, urinary obstruction.

Alert
Findings suggestive of an STI/STD infection should raise concern for sexual abuse.

Treatment
General Measures
- Initial, empirical treatment should be based on clinical suspicion of UTI as well as reliability of patient and family.
- As the symptoms are often vague, a high index of suspicion must be maintained to ensure early detection of pyelonephritis.
- Hospitalization might be required based on patient age and clinical status, although infants <2 mos and nonurologic children with suspected pyelonephritis can be treated as outpatients as long as compliance is not an issue.
- Children with asymptomatic bacteriuria may not require treatment with antibiotics if the urinary system is otherwise normal.

Medication
Alert
- In children, use 7–14-day treatment course (~7 days has been shown to be effective).
- Fluoroquinolones should not be a 1st-line choice for children overall.
- 3rd-generation cephalosporins: Ceftriaxone, Cefixime, Cefdinir.
- Children <2 yr of age should be treated with pharmcodynamic (B/L, P, or combination).
- School-aged children without systemic symptoms may be treated with an oral broad-spectrum antibiotic such as AMX-TMP, nitrofurantoin.
- Appropriate to start broad-spectrum antibiotics while awaiting culture results (5).

Second Line
- Antibiotic course should be tailored by comorbidities, age, and local bacterial resistance patterns.

Surgery/Other Procedures
- May be indicated following resolution of infection if child has specific urinary abnormalities predisposing to or exacerbating effects of urinary tract infection (eg, obstruction, VUR).
- Surgical correction of reflux is aimed at protecting upper tracts and is associated with a decrease in the number of future UTIs.

Additional Treatment
- In children with UTIs and dysfunctional voiding/elimination behaviors, improvement in the latter will often result in fewer recurrent UTIs.
- Regular (eg every 2 h) voiding.
- Avoidance of constipation.

Radiation Therapy
N/A.

Additional Therapies
N/A.

Complementary & Alternative Therapies
- Cranberries may be effective in decreasing bacterial adherence, but there are no specific recommendations for children at present.
- Probiotics may favorably alter gastrointestinal flora, but again there are no specific recommendations for use.

Ongoing Care
- Infants <2 mo (IV therapy preferred).
  - Amoxicillin/trimethoprim: ~7 d; 50–100 mg/kg/24 h IV, q6h; Term infants: 75–150 mg/kg/24 h, q6–8h; Children >1 mos: 200 mg/kg/24 h IV, q6h R or IV
  - Gentamicin: Infants ~7 d; 1200 mg/24 h IV, q8h; Children >1200 mg/24 h, q12h; Children <2.5 mg/kg/dose IV, q12h; Children <2.5 mg/kg/dose IV = q6h, ≤ renal insufficiency.
- 3rd-generation cephalosporin.
- Ceftriaxone: 8 mg/kg PO – daily bid, q12h in renal impairment.
- Ceftriaxone: 7 mg/kg PO bid or 14 mg/kg PO, q12h in renal impairment.
- Ceftobiprol: 9 mg/kg PO, q12h in renal impairment; take on empty stomach (susp).
- Children >2 mo.
  - 3rd generation cephalosporin: Ceftriaxone, Cefixime, Cefdinir.
  - Children <2 yr of age should be treated with pharmcodynamic (B/L, P, or combination).

Codes
ICD-9: N39.0 Urinary tract infection, site not specified
771.82 Urinary tract infection of newborn
599.0 Urinary tract infection, site not specified
771.82 Urinary tract infection of newborn

ICD-10: B96.20 Urinary tract infection as the cause of disease classed elsewhere
N90.9 Urinary tract infection, site not specified
P39.3 Nephrolithic urinary tract infection

Clinical/Surgical Pearls
- A high index of suspicion is often required for an accurate diagnosis of UTI, especially in nonverbal children.
- Treatment of the acute infection should be tailored to the child’s age, comorbidities, and clinical condition, as well as local antibiotic resistance patterns and culture results.
- Surgical intervention is undertaken when conservative management is unlikely to prevent further UTIs and/or protect the kidneys.
- Patients with recurrent febrile infections, VUR, and/or kidney scarring should be followed carefully for development of renal disease.

Margaret S. Pearle, MD, PhD, FACS
Jodi A. Antonelli, MD

BASICS
DESCRIPTION
• Calculus that occurs in the urinary tract
• May be asymptomatic but can also be associated with mild to severe symptoms

EPIDEMIOLOGY
RISK FACTORS
Incidence
• More common in Caucasians than in Hispanics, Asians, or African Americans
• More common in men, increasing in women
Prevalence
• Prevalence in US adults is 8.8% (10.6% for men, 7.1% for women) (1)
• Prevalence gradient increases from North to South and West to East

PATHOPHYSIOLOGY
• Hyperoxaluria—Urine oxalate
• Hypercalciuria—urine Ca
• Calcium (Ca) stones—occur in settings of
• Most common stone—calcium oxalate (60%)
• Comorbidities: chronic diarrheal states, GI surgery, gout, diabetes, recurrent UTIs hyperparathyroidism, cystinuria, type I renal tubular acidosis, sarcoidosis
• Anatomic anomalies: Ureterointestinal junction obstruction, horseshoe kidney, caliceal diverticula, medullary sponge kidney

GENETICS
• Multiple genetic polymorphisms may contribute to calcium stone formation
• Nephritic disorders: Primary hyperoxaluria, cystinuria, Lesch–Nyhan syndrome, xanthinuria, type I renal tubular acidosis

PATHOPHYSIOLOGY
• Most common stone—calcium oxalate (60%)
• Calcium (Ca) stones—occur in settings of hypercalciuria, hyperoxaluria, hypocitraturia, hyperuricosuria
• Hypercalciuria—urine Ca > 200 mg/d
• Absorptive hypercalciuria—Increased intestinal absorption of Ca
• Renal hypercalciuria—Impaired renal reabsorption of Ca
• Nephrocalcinosis—Primary hyperparathyroidism, renal cystic disease
• Hyperoxaluria—Urine oxalate > 40 mg/d
• Primary hyperoxaluria—Excess endogenous oxalate production
• Enteral hyperoxaluria—Increased intestinal absorption of oxalate
• Dietary hyperoxaluria—Overindulgence in oxalate-rich foods, Ca restriction, excess vitamin C supplementation, reduced Oxalobacter formingens (oxalate-degrading intestinal flora)
• Hyperuricosuria—Uric acid (UA) > 600 mg/dl
• Causes: excess animal protein intake, gout, myeloproliferative disorders
• Urate pH < 5.5—Uric acid or calcium stones
• Urate pH > 5.5—Cystine stones
• Hypocitraturia—Urine citrate < 120 mg/dl
• Low urine citrate occurs in states of acidosis—Renal tubular acidosis, chronic diarrhea
• Uric acid stones—Rudolphstein
• Congenital causes—Disorders of renal tubular urine transport, disorders of UA metabolism
• Acquired causes—Obesity, high animal protein intake, volume depletion
• Cystine stones
• Cystinuria—Inherited disorder of impaired renal absorption of cystine
• Infection stones—Composed primarily of meprotein, ammnonium, and phosphate
• Alkaline urine produced by unass-splitting bacteria—Proteus (most common), Enterobacter, Pseudomonas, Staphylococcus
• Miscellaneous stones
• Xanthine—Rudolphstein, inherited disorder of the enzyme (ADH) that catalyzes xanthine to UA, another cause—high-dose Allopurinol use
• Ammonium acid urate—Associated with laxative abuse, inflammatory bowel disease (IBD), hyperlipidemias
• Cystine—Typically radiolucent, associated with infection, may contain protein
• Medullary sponge kidney

ASSOCIATED CONDITIONS
• Chronic diarrheal states, GI surgery, gastric bypass, small bowel resection
• Hyperparathyroidism
• Gastric ulcers
• Pancreatic pseudocysts
• Gallstones
• Cystinuria
• Type I renal tubular acidosis
• Medullary sponge kidney

DIAGNOSIS
HISTORY
• Can be asymptomatic
• Personal/family history of kidney stones
• Gross hematuria
• Pain—Frank, abdomen, ipsilateral groin—Renal colic—Pain in flank when stones occur in ureters
• Acute colics may suggest obstruction
• Nausea/vomiting—may suggest obstruction

PHYSICAL EXAM
• Can be unremarkable
• Elevate heart rate and blood pressure—pain
• Rectal, uterine, rectovaginal, or sigmoid tenderness
• Costovertebral angle tenderness

DIAGNOSTICS TESTS & INTERPRETATION
Lab
• Urinalysis—Microhematuria, pyuria
• Crystalluria—Hexagonal (cystine), coffin lid (MAP), dumbbell (Ca oxalate monohydrate)
• Leukocyturia/felourea—Inflammation and/or infection
• Elevated serum osteocalcin—Bilateral obstruction or solitary kidney

Imaging
• Non-contrast CT of abdomen and pelvis—Gold standard to identify urinary stones
• Low-dose protocol limits radiation exposure
• Provides additional anatomic information: Hydronephrosis, kidney stones, and other visera
• Plain radiography: Not as sensitive or specific as CT for stones, useful for follow-up
• Ultrasound—Often difficult to visualize adult urothelium, first-line for pregnant women, consider transvaginal ultrasound for pregnant women
• Intravenous pyelography (IVP)—Arterial anatomy of collecting system, renal function, obstruction; limited availability, must give IV contrast; CT urography generally replaces this
• MRI—Poor for stones of all types; some value in patients with renal transplant

DIFFERENTIAL DIAGNOSIS
• Any of the following causes may be confused with pain related to urolithiasis:
  • Vascular: Abdominal aortic aneurysm, mesenteric ischemia
  • Gastrointestinal: Appendicitis, bowel obstruction, choledocholithiasis, colic, constipation, diverticulitis/diverticulosis, pancreatitis, peptic ulcer
  • Gynecologic: Uterine fibroids, ovarian torsion/rupture
  • Musculoskeletal—Back pain
• Urolithiasis—Pyelonephritis, urinary tract infection, sloughed renal papilla, ureterointestinal junction obstruction

Stone analysis—Ca oxalate monohydrate or dihydrate, Ca phosphate, uric acid, cystine, struvite, mixed

Differential diagnosis
• Any of the following causes may be confused with pain related to urolithiasis:
  • Vascular: Abdominal aortic aneurysm, mesenteric ischemia
  • Gastrointestinal: Appendicitis, bowel obstruction, choledocholithiasis, colic, constipation, diverticulitis/diverticulosis, pancreatitis, peptic ulcer
  • Gynecologic: Uterine fibroids, ovarian torsion/rupture
  • Musculoskeletal—Back pain
• Urolithiasis—Pyelonephritis, urinary tract infection, sloughed renal papilla, ureterointestinal junction obstruction

Stone analysis—Ca oxalate monohydrate or dihydrate, Ca phosphate, uric acid, cystine, struvite, mixed
TREATMENT

GENERAL MEASURES

ALERT

- Fever, leukocytosis/akoncentration, tachycardia, hypotension, tachypnea, bacteriuria, and/or pyuria with upper tract stone is life-threatening; treat with renal decompression (ureteral stent or nephrostomy tube).
- \*Conservative therapy:
  - Hydration, analgesia, medical expulsive therapy (best evidence for alpha-blockers)
- \*Medical expulsive therapy
  - \% success with conservative measures:
    - 80%—Stone 3–3 mm
    - 50%—Stone 4–5 mm
    - 20%—Stone 6–8 mm
  - Direct instructions to return for fevers, worsening pain, unable to tolerate oral fluids
- \*Relative indications for intervention:
  - Large stone burden—Staghorn or partial staghorn
  - Large or pelvic stone
  - Stone location—Renal pelvis, ureter
  - Concern for infection; severe pain
  - Unable to tolerate oral fluids
  - Renal deterioration, solitary kidney
  - Repeated presentations to emergency room

601
Hypercalciuria may be heterogeneous.

### Pathophysiology

#### Incidence

- **US annual stone incidence:** 164,100
- **Male:** 3:1–2:1
- **Age of peak incidence:** 20–40 yr
- **1 in 10 men, 1 in 20 women lifetime risk**

#### Stone Incidence by Composition

- Calcium oxalate: 30–56%; mixed Ca oxalate and Ca phosphate: 11–31%.

#### Prevalence

- **10–15%** US prevalence of stones
- **Lifetime prevalence of kidney stone disease is estimated at 1–15%, with the probability of having a stone varying according to age, gender, race, and geographic location.**

#### Risk Factors

- **See also Section II: “Urolithiasis, Risk Factors.”**
- **Intrinsic:** Polygenic defect; hypercalciuria inherited as autosomal dominant trait; white males; other ethnicities (IBD, etc.), elevated PTH
- **Extrinsic:** UPI obstruction, horseshoe kidneys
- **Environmental:** Fat malabsorption causes Ca to complex with bile acids and form Ca soap, which decreases free Ca absorption.

#### Baseline Evaluation

- A comprehensive metabolic evaluation (with Ca and Na restriction) prior to fast and load Ca studies; renal hypercalciuria by reducing the suppressive effect of absorbed Ca on parathyroid stimulation

#### Other Causes of Calcium Oxalate Stones

- **Hyperoxaluria:**
  - **Primary hyperoxaluria type I:**
    - Autosomal recessive, defect of AGT
    - 200 mg/24 hr
  - **Primary hyperoxaluria type II:**
    - Autosomal dominant, defect of AGT
    - 45 mg/24 hr

#### Associated Conditions

- **Primary hyperparathyroidism:**
  - Elevated HCT, medullary sponge kidney, UTIs

#### General Prevention

- See “General Measures” below

### Diagnosis

#### History

- **“Flank Pain” and “Urolithiasis, General.”**
- **Review stone history, family history, and the intrinsic and extrinsic risk factors of a patient’s stone.”

#### Physical Exam

- See “Flank Pain” and “Urolithiasis, General.”

### Diagnostic Tests & Interpretation

- **Lab (1):**
  - **Abnormal protocol for low-risk single-stone formers:**
    - Urinary calcium, creatinine, urinary oxalate, citrate, uric acid, sulfate
    - 24-hr urine analysis (Ca, oxalate, citrate, Na, phosphate, magnesium, pH, uric acid, sulfate)

### Urinary Calcium, Oxalate/Phosphate

**John J. Pahira, MD**
GENERAL MEASURES

Imaging

- CT: Most sensitive
- US, KUB, Excretory Urography (EU)
- MRI not useful for calcifications/surgical calculus

Do not use for stone analysis.

Diagnostic Procedures/Surgery

- In deciding which stone formers require a metabolic evaluation, consider the following:
  - 80–90% have predisposing urinary abnormality or underlying disease identified.
  - Treatment programs to be maintained for life.
  - 50–60% patients pass only 1 stone/lifetime.
  - Involve your patient in the decision to perform a workup, explain risk and benefits.

- Criteria for metabolic evaluation:
  - Anatomic abnormality, family history of stones, history of great or major stone complications, history of metabolic stone (uric acid or cystine), infestation stone (intravesical, pure Ca phosphate stone, RTA), or elevated PTH
  - Metabolically active (x-ray evidence of new stone or stone growth in the past year or the documented passage of a new stone or gravel)
  - Osteoporosis or pathologic skeletal fracture
  - Recurrent stone formation
  - Renal insufficiency
  - Significant number of risk factors
  - Tertiary therapy: age at onset <20 yr

Pathologic Findings

- Stone analysis: Varying percent composition from Ca oxalate and/or Ca phosphate
- Crystals: Ca oxalate monohydrate (dihydrate/amorphous), Ca oxalate dihydrate (envelope/bipyramidal), Ca phosphate-apatite (dumbbell/hourglass), Ca oxalate dehydrate

DIFFERENTIAL DIAGNOSIS

- Hypercalciuria: Primary elevated PTH, RTA, vitamin D excess, immobilization, sarcoidosis, metabolic maladies, milk-alkali syndrome, hyperparathyroidism, myeloma, adrenal insufficiency, fetus/infantile administration

- See: "Section I Flank Pain: Upper Urinary Tract."
- See: "Section I Tissue.

TREATMENT

GENERAL MEASURES

- Treat active UTI.
- Medical expulsion therapy for a symptomatic infection stone (struvite), pure Ca phosphate stone, or stone growth in the past year or the documented passage of a new stone or gravel

TREATMENT

MEDICATION (3)

First Line

- Absorptive hypercalciuria type I: Thiazide (not a selective therapy for AIH as it does not decrease intestinal Ca; initial long-term effect:– Hydralazine/Indapamide 25–50 mg b.i.d.
  - Indapamide C. r. 20 (20–40 mg b.i.d.):– Alternates: Indapamide 1.25–2.5 mg/d or furosemide (25–50 mg/d)
  - Restrict dietary oxalate, Na to 2000 mg/d
  - Magnesium supplementation
  - Art type II: Moderate Ca restriction (600 mg/d or 1–2 servings dairy/d); Na restriction; thiazide if not effective; K citrate supplementation
  - Art type III: orthophosphate (Neutra-Phos-K)

- Renal hypercalciuria: Thiazide to increase tubular Ca reabsorption; hydralazine/Indapamide 25–50 mg b.i.d.
  - Indapamide C. r. (20–40 mg b.i.d.)
  - K citrate supplementation (Polykala K syrup 15–30 ml); (Polykala K crystal: 1 packet b.i.d.; Urocit K 10–20 mg b.i.d.); Na restriction (2 g Na diet); be sure urinary Na < 100 mg/d

- Hypouricosuric Ca nephrolithiasis: Increase fluid intake; reduce dietary purine (eg, red meat); urinary alkalization (pH 6.5–7.0); K citrate; reduce endogenous uric acid production (allopurinol 300 mg/d); if serum uric acid > 8 mg/dL; or if uncorrectable hyperuricosuria

- Hyperparathyroidism: Ca nephrolithiasis type K: evidence of renal hypercalciuria, or stone (RTA or elevated PTH)

- See "Section I Flank Pain: Upper Urinary Tract."

- See: "Section I Tissue."

- See: "Section I General."

TREATMENT

ADDITIONAL TREATMENTS

- Additional Therapies
  - Hypercalciuria
  - Complementary & Alternative Therapies

FOLLOW-UP

- Patient Monitoring
- Provide patients with appropriate written dietary handouts
- Patients with recurrent stones on medical therapy require periodic monitoring:
  - Urine analysis, urine pH
  - Serum chemistry if warranted
  - 24-hr urine collection
  - KUB, US, or CT

Patient Resources

Urology Care Foundation: http://www.urologyhealth.org

CLINICAL/SURGICAL PEARLS

- A family history of nephrolithiasis is important risk when deciding on a metabolic work-up.
- A slight increased PTH is best indication of renal leak hypercalciuria with normal ATP and persistent hypercalciuria on a restricted diet.
- When starting on a thiazide for hypercalciuria, it is important to check serum calcium in 2–4 wk to rule out an occult hyperparathyroidism.
- Accurate 24 hr urine uric acid cannot be done until the patient is placed on urinary alkalization or acidic urine can cause uric acid to precipitate out of solution causing underestimation.

- Ongoing care
  - Untreated recurrence for Ca oxalate stones: 10% at 1 yr, 35% at 5 yr, 50% at 10 yr.
  - Medical therapy: Decrease new stone formation; elimination >90% and >90% reduction in stone recurrence.
  - Alternates:
    - Ongoing care: see above.
  - Treatment program is to be maintained for life.
  - 80–90% have predisposing urinary abnormality or underlying disease identified.

- Ongoing care
  - Untreated recurrence for Ca oxalate stones: 10% at 1 yr, 35% at 5 yr, 50% at 10 yr.

UROLITHIASIS, CYSTINE, AND CYSTINURIA (HYPERCYSTINURIA)
Anthony J. Tracey, MD, MPH
Raju Thomas, MD, MHA, FACS

DESCRIPTION
Cystinuria is an autosomal recessive error of transepithelial transport involving the intestine and the kidneys. Cystinuria is the clinical result of crystallization and stone formation in the urinary tract.

- Excessive urinary excretion secondary to reduced tubular absorption of cystine disulfate (1).
- There is a transport defect of dibasic amino acids including cystine, ornithine, lysine, and arginine (COUAs). (See also Section I: “Urolithiasis.”) (1)
- Cystinuria form when concentrations rise above the saturation point (roughly 250 mg cystine per liter of urine).
- Cystinuria accounts for about 1–2% of adult and 6–8% of pediatric nephrolithiasis (1).
- Historical, three types of cystinuria have been recognized in humans—Type I, Type II, and Type III—on the basis of levels of urinary cystine in obligate heterozygotes; however, this classification correlates poorly with molecular findings; newer genetic classification is available (see below).
- Cystinuria is distinct from cystinosis.

Epidemiology
Incidence
- For patients with cystinuria:
  - An average of one surgical procedure every 3 yr.
  - A mean number of stone episodes of 0.42 and 0.21 per year occurring in men and women, respectively.

Prevalence
- Homozygous: 1 in 15,000 in the United States
- Heterozygous: 1 in 20–200 in the United States
- Libyan Jews: 1 in 2,500 (3)
- Cystinuria is more common in Caucasians.
- Cystine stones are common in the second or third decade of life.
- 20% of these patients develop calculi in childhood.

Risk factors
- Family history (see genetics)

Genetics
- Identification of genetic mutations that cause cystinuria have led to a new classification system based on genotype that is more accurate than the prior phenotypic one.
- Mutations in 2 genes, SLC3A1 and SLC7A9 (3)

RISK FACTORS
- Prevalence
- Incidence
- Description

PATHOPHYSIOLOGY
- Cystine is homodimer of the amino acid cystine. Cystinurics have impaired renal cystine transport, with increased proximal tubular reabsorption of filtered cystine resulting in increased urinary cystine excretion with the consequence of cystine urolithiasis.
- Clinical consequences present only when crystals precipitate (low cystine solubility at normal urinary pH values).
- Cystine stone formers have slightly lower creatinine clearance than other types of stone formers.

ASSOCIATED CONDITIONS
- Deleterious renal acidification
  - Hypercalciuria 19%
  - Hypokaliemia 22%
  - Hypophosphatemia 44%
  - Urolithiasis

GENERAL PREVENTION
- Create high urine volume (<1.3 L/m²/d) to reduce the urinary concentration of cystine to below its solubility limit (200–300 mg/L).
- Alkalize urine to pH of 7.5 ± 0.4 mg/L (glutamic acid, citrate, or sodium bicarbonate) in 3–4 divided doses.
- Avoid alkali (but do not restrict carbonates).
- Restrict sodium and protein.

RISK FACTORS
- Family history (see genetics)
- Prevalence
- Incidence
- Description

DIAGNOSIS
- History
- CT scan of abdomen without contrast
- Imaging
- Diagnostic procedures/Surgery

HISTORY
- Stones in childhood (3)
- Family history of stones (3)
- Presentation of a large branched calculi

PHYSICAL EXAM
- C/S tenderness may be present with acute stone disease.

DIAGNOSTIC TESTS & INTERPRETATION
- Lab
  - Urine is screened for cystine using the cyanide-nitroprusside test (positive = purple hue with cystine >75 mg/dL).
  - Cystine converts cystine to cysteine; this binds nitroprusside then binds resulting in a purple color usually in <10 min.
  - If positive, a 24-hr urine quantitative test is performed.
    - Normal cystine excretion is 30 mg (0.13 mmol/d).
    - Cystinuria >400 mg/dL (1.7 mmol/d) (1).
    - Heterozygous for cystinuria and with the Fanconi syndrome, excrete >250 mg/dL (1 mmol/d) and usually do not form stones.

IMAGING
- CT scan of abdomen without contrast
- Preferred imaging modality

- KUB may show stones with a fuzzy gray appearance (1).
- Stones are less radiopaque than calcium stones that usually well seen.

Physics and Imaging
- More economical than CT scan for monitoring the growth of renal calculi.
- Indicated for children and frequent stone formers to reduce radiation (2).

UROLOGIC FINDINGS
- Renal biopsys is not usually performed. However, renal pathology may include plugging of the ducts of Bellini with cystine crystals, tubular dilation, and focal fibrosis.

DIAGNOSTIC PROCEDURES/SURGERY
- KUB
- N/A
URINARY CALCULI, CYSTINE, AND CYSTINURIA (HYPERCYSTINURIA)

DIFFERENTIAL DIAGNOSIS

- Other forms of urolithiasis (calcium oxalate, uric acid, etc.)
- Any of the following may be confused with pain related to urolithiasis:
  - Vascular: Abdominal arterial aneurysm, mesenteric ischemia
  - Gastrointestinal: Appendix, bowel obstruction, cholecystitis/biliary colic, constipation, diverticulitis/diverticula, gastritis, pancreatitis, peptic ulcer
  - Gynecologic: Septic pregnancy, tubo-ovarian abscess, ovarian torsion/cyst rupture
  - Musculoskeletal: Back pain
  - Urologic: Pyelonephritis, urinary tract infection, sloughed renal papilla, ureterosigmoid junction obstruction

TREATMENT

GENERAL MEASURES

- For existing calculi treatment is similar to other stones based on clinical indication
- Extracorporeal shockwave lithotripsy has been discouraged for stones > 1 cm by some authors (2)
- Cystine stones are often not well fragmented by ESWL (extracorporeal shock wave lithotripsy)
- Multiple treatments are usually required
  - Algorithm for Patients with Renal cystine stones:
    - Percutaneous nephrolithotomy (PNL) for cystine renal calculi larger than 15 mm in diameter
    - Ureteroscopy effective for cystine ureteral stones and for select renal cystine calculi
    - Laparoscopic pyelolithotomy may also be possible for stones in favorable locations of the ureter or renal plexus.
    - ESWL monotherapy for cystine renal calculi 15 mm or smaller (High failure rate)

MEDICATION

First Line

See general prevention

Second Line

- Use chelating agents (bind cystine) only if the conservative methods do not work
- These inorganic cystine solubility in urine via formation of a more soluble mixed-disulfide bond
- These medications have potentially serious side effects and must be monitored
  - Mercaptopropionylglycine (Thiola, Tiopronin)
    - Most frequently used cystine-binding agent
    - Dosage start at 100 mg, orally two times per day, doses titrated to achieve urinary concentrations of cystine less than 250 mg/L urine.
    - Side effects: include asthma, GI distress, rash, joint aches, and mental status changes
  - Etoposide (Etopophrine)
    - Better tolerated than p-penicillamine
  - D-penicillamine (Cuprimine)
    - Binds with cystine to yield a disulfide more soluble than cystine
    - Typically start therapy at 250 mg per day and titrate to effect
    - Typical side effects: nephrotic syndrome, dermatitis, and pancreatitis.

- Captopril: Potential alternative
  - More favorable side effect profile: Fatigue, hypotension, and chronic cough
  - No long-term clinical trials describe the effectiveness of captopril in preventing recurrent cystine stone formation

SURGERY/OTHER PROCEDURES

See General Measures above

ADDITIONAL TREATMENT

Radiation Therapy

- Additional Therapies
  - Complementary & Alternative Therapies

ONGOING CARE

PROGNOSIS

- One study reported 1.22 stone episodes per year (2)
- The medical compliance of patients with cystinuria can be poor.
- A few patients are able to achieve and maintain targeted goals of medical intervention
  - 33% achieved and maintained therapeutic success, as defined by urine cystine concentration less than 300 mg/L.
  - 15% achieved and maintained therapeutic success but subsequently had failure at an average of 16 mo.
- The Renal Stone Consortium has developed a registry and will lead further efforts in managing cystinuria

COMPLICATIONS

- Studies report 1.22 stone episodes per year
- Chronic cystinuria—19%
- Renal impairment—Approximately 70% (2)
- Risk for nephrectomy—10–20%
- End stage renal failure—5%
- Hypertension—10%
- Mental illness and mental retardation (2)

FOLLOW-UP

Patient Monitoring

- Patients should have frequent clinical, radiologic, and laboratory surveillance
  - Patients should follow a diet low in protein and sodium chloride
  - Urinary pH level, and check first-morning urine for cystine crystals
- Regularly check renal function
  - CBC counts, WBC counts, and platelet counts should be monitored for patients on p-penicillamine and tiopronin (2)
- EUS and renal ultrasound should be the routine Surveillance:
  - Annually perform 24-hr urine testing and imaging for patients with stable disease (2)
  - Multidisciplinary approach early in disease
  - Nephrologists
  - Urologists
  - Radiation Therapy

  - N20.9 Urinary calculi, unspecified

CLINICAL/SURGICAL PEARLS

- Cystine stones are often not well fragmented by ESWL, and may be considered for cystine renal calculi > 15 mm.
- Consider PCNL for cystine renal calculi larger than 15 mm in diameter.
- Ureteroscopy effective for cystine ureteral stones and for select renal cystine calculi.
UROLITHIASIS, PEDIATRIC, GENERAL CONSIDERATIONS

Gregory E. Tassign, MD, MSc
Douglas A. Canning, MD, FACS

DESCRIPTION

Urolithiasis can be found anywhere in the urinary tract of a child.

Urolithiasis is much less common in children than adults.

Urolithiasis is an increasingly common disease of childhood.

The most common stones in children are calcium (calcium oxalate and calcium phosphate), uric acid, struvite and cystine.

EPIEMIOLOGY

Incidence

In adolescents, the incidence of nephrolithiasis has increased 6–10% per year over the last 20 yr (1,2).

White = African American

Male = Female

Increased incidence in the Southwest United States.

Prevalence

The prevalence is unclear.

RISK FACTORS

When a metabolic evaluation is performed, an abnormality can be identified in 40–50% of children.

Most common metabolic abnormalities are hypercalciuria and hypocitraturia.

PATHOPHYSIOLOGY

Stone formation involves nucleation and growth. Nucleation is the process by which a theoretical nucleus forms, which is then supersaturated with respect to a crystalline phase. Growth occurs when one crystal is able to catalyze the growth of another.

Metabolic evaluation

A metabolic evaluation is performed when a child presents with recurrent urolithiasis.

Phenotypic and genotypic abnormalities are divided into three categories:

1. Inherited abnormalities
2. Secondary metabolic abnormalities
3. Sporadic or idiopathic abnormalities

Inherited abnormalities are divided into the following categories:

A. Autosomal recessive
B. Autosomal dominant
C. X-linked

Special consideration is given to hyperoxaluria and cystinuria.

The most common metabolic abnormalities are hypercalciuria and hypocitraturia.

DIAGNOSTIC TESTS & INTERPRETATION

PHYSICAL EXAM

Lab

Acute Episode: Urinalysis

- Microscopic or microscopic hematuria is found in 85% of children with nephrolithiasis (3).

- Metabolic evaluation

- Following the resolution of the acute stone episode, obtain at least one 24-hr urine collection in children who are toilet trained.

- Analyze for calcium, oxalate, uric acid, sodium, chloride, creatinine levels, volume, pH, and cystine.

- It is essential to evaluate the results with respect to weight and creatinine level to accurately interpret the results.

- Hypercalciuria is defined by a urinary calcium excretion of greater than 4 mg/kg over 24 hr while ingesting a routine diet.

- Urine creatinine excretion (normal 15–25 mg/kg/d) is useful in assessing the adequacy of the urine collection.

- Urine calcium—creatinine ratio (Ca/Cr) from a spot urine sample should be obtained in children who have not been toilet-trained.

- Except for neonates, there is an inverse relationship between age and Ca/Cr.

- At approximately 5 years of age, Ca/Cr approaches 0.21, the upper limit of normal for adults (4).

Imaging

- Ultrasonography: Reliable when it identifies a kidney stone, but it has only moderate sensitivity specifically for stones in the mid-ureter.

- CT: Accurate but delivers ionizing radiation, concerns for increased cancer risk, particularly with exposure at young age.

A reasonable approach is to use US as the initial study. A non-contrast CT is indicated in children with persistent symptoms of nephrolithiasis and a non-diagnostic US.

UROLOGY, PEDIATRICS, GENERAL CONSIDERATIONS

DIAGNOSIS

HISTORY

- Patient: Prematurity, medications, dietary habits, fluid consumption, malignancies, previous iatrogenic disorder/surgery, hematuria

- Family: Cystinuria, primary hyperoxaluria, RTA, uric acid lithiasis

- Abdominal/flank pain ± nausea/vomiting

PHYSICAL EXAM

- Occasional abdominal or flank tenderness

- Growth charts may identify decreased growth patterns associated with certain childhood diseases associated with stones (cystinuria, distal RTA, hyperoxaluria, etc.)
MEDICATION

GENERAL MEASURES

- Indications for surgery: When the presence of an obstructing stone, plain radiography to exclude stones, acute kidney injury, and an obstructing stone in a solitary kidney.
- Evaluate all children for underlying metabolic disorder.
- Goal is to decrease stone-promoting risk factors (urinary calcium, sodium, oxalate, uric acid, and low urine volume), and increase protective factors (urine pH, citrate, magnesium).

Hydration:
- Water preferred; avoid caffeine, sodium, and sugary drinks (sports drinks).

Dietary modifications when applicable
- Goal is to decrease stone-promoting risk factors
- Evaluate all children for underlying metabolic disorder.
- Dietary modifications when applicable

TREATMENT

GENERAL MEASURES

- Indications for surgery: When the presence of an obstructing stone, plain radiography to exclude stones, acute kidney injury, and an obstructing stone in a solitary kidney.
- Evaluate all children for underlying metabolic disorder.
- Goal is to decrease stone-promoting risk factors (urinary calcium, sodium, oxalate, uric acid, and low urine volume), and increase protective factors (urine pH, citrate, magnesium).

Hydration:
- Water preferred; avoid caffeine, sodium, and sugary drinks (sports drinks).

Dietary modifications when applicable
- Goal is to decrease stone-promoting risk factors
- Evaluate all children for underlying metabolic disorder.
- Dietary modifications when applicable

MEDICATION

First Line
- Should a trial of spontaneous passage be indicated, appropriate oral analgesics are important (ie, narcotics).

Second Line
- Hyperuricosuria:
  - Allopurinol (decrease uric acid production): Adult 30–90 mEq/d; children 1–2 mg/kg/d.
- Hypocitraturia:
  - Potassium citrate: Adults 25–100 mg/d, children 1–2 mg/kg/d.
- Hypercalciuria:
  - Limit dietary sodium and milk.
- Uric acid stones:
  - Allopurinol (decrease uric acid production).

Cystinuria
- Create high urine volume (>1.5 L/m²).

Hyperoxaluria
- Limit sodium and oxalate-rich foods (eg, spinach, rhubarb, nuts, tea, bran, strawberries).

Hypomagnesemia
- Magnesium, diuretics.

SURGERY/OTHER PROCEDURES

- The optimal management based on the size, location, and presumptive stone composition, as well as the age, size, and health of the patient.

Complications
- Subcapsular hematoma: Self-limited
- Interstitial fibrosis: Insignificant unless multiple procedures
- Injury to surrounding organs:
- Ureteroscopy:
  - Rigid and flexible endoscopes permit access to almost all areas of the collecting system in nearly all children.
  - Pre-placement of stent is sometimes necessary to passively drain the ureter.

Acute calculous cholecystitis:
- Access sheaths (without pre-stenting) facilitate procedures requiring multiple endoscope passes.
- All forms of lithotripsy are safe; holmium laser most effective.
- Percutaneous nephrolithotomy (PCNL):
  - Appropriate for large intrarenal/pelvicalyceal ureteral stones.
  - Also failed primary procedures (SWL, ureteroscopy), and with associated anatomic abnormalities (congenital, acquired, etc).
  - Access at same time as or prior to surgery:
    - Smaller size as small as possible to allow for successful procedure and to accommodate flow of irrigant around scope.
    - Renal access: best access to stone burden.
    - Multiple tracts are safe.
    - Ureteroscopy: Always when possible to allow for successful procedure and to accommodate flow of irrigant around scope.

Ongoing care

- Adequate hydration to dilute urine.

Follow-up

- Patient monitoring: Repeat 24-h urine 3–4 mo after initial surgery.
- Assess periodically for stone growth or new or recurrent disease with US.

Codes

- ICD9: 592.0 Calculus of kidney
- N20.9 Urinary calculus, unspecified

-U-
UROLITHIASIS, RENAL

Aaron G. Boonjindasup, MD, MPH
Raju Thomais, MD, MHA, FACS

BASICS

DESCRIPTION
- Renal urolithiasis refers to kidney stones within the kidney itself (parenchyma, calyces or renal pelvis). The majority of stones in the urinary tract have their origin in the kidney.
- Renal urolithiasis is a significant cause of patient renal morbidity and a major source of medical costs in the United States.
- Calcium oxalate stones are most common; also uric acid, struvite (magnesium ammonium phosphate), cystine, carbonate apatite, etc.

Epidemiology
Incidence
- Estimated to be 10–15% in the United States
- Males are affected 2–3 times more than females
- Peak incidence: 4th–6th decades
- More common in Southeast, Southwest, and Northwest United States
- Increasing incidence with increased obesity
- Accounts for 7–10% of every 1000 hospital visits

Prevalence
- Highest prevalence in Caucasians

Risk Factors
- Calcium stone formation
  - Dietary excess
  - Hyperparathyroidism
  - Inappropriate loss of calcium in urine through malabsorption
- Uric acid stone formation
  - Purine excessive intake
  - Gout
  - Myeloproliferative disorders
- Struvite stones
  - Chronic dehydration
  - Escherichia coli syndrome
  - Ingestion of urolithic drugs
- Cystine stones
  - Inherited disorder of renal tubular reabsorption of cystine (See Urolithiasis, Cystine)

Genetics
- In general, urolithiasis is associated with polygenic defect and partial penetrance
- Cystinuria: Homozygous recessive
- Renal tubular acidosis (RTA): Inherited

Pathophysiology
- Supersaturation: Urine oversaturated with certain types of crystal, which then is precipitated out of solution.
- Saturation level is variably pH dependent based on crystal type
- Inhibitor deficiency: Inhibitors may limit crystal growth and aggregation
- Urinary citrate and magnesium are inhibitors
- Non-infection stones: Calcium oxalate, calcium phosphate (brushite, carbonate apatite), uric acid
- Infection stones: Magnesium ammonium phosphate (struvite), carbonate apatite, ammonium urate
- Genetic defects: Cystine, xanthine, 2,8-dihydroxyadenine (DHA)
- Drug stones: Indinavir, trimethoprim, others

Associated Conditions
- Congenital malformations or anatomical variations of kidney, collecting system, ureter, or bladder may predispose patient to urolithiasis due to stasis and/or impaired urine drainage
- Cystinosis
- Dehydration
- Gout
- Inflammatory bowel disease
- Intravenous pyelography
- Intestinal bypass
- Medullary sponge kidney
- Renal tubular acidosis

General Prevention
- Decreased sodium intake
- Renal tubular acidosis
- Stones may form
- Decreased calcium intake
- Stones may form
- Increased urinary citrate
- Patients with RTA
- Increased magnesium intake
- Patients with RTA
- Decreased protein intake (purine) if at-risk
- Decreased oxalate consumption
- Ingestion of uricosuric drugs
- Patients with gout
- Urine oversaturated with certain types of crystal, which then is precipitated out of solution.
- Saturation level is variably pH dependent based on crystal type
- Inhibitor deficiency: Inhibitors may limit crystal growth and aggregation
- Urinary citrate and magnesium are inhibitors
- Non-infection stones: Calcium oxalate, calcium phosphate (brushite, carbonate apatite), uric acid
- Infection stones: Magnesium ammonium phosphate (struvite), carbonate apatite, ammonium urate
- Genetic defects: Cystine, xanthine, 2,8-dihydroxyadenine (DHA)
- Drug stones: Indinavir, trimethoprim, others

Diagnostic Tests & Interpretation
Lab
- Urinalysis
  - Microscopic hematuria
  - Urine culture (sterile, complete obstruction)
  - Crystaluria may provide important information regarding the type of calculus
- Pyuria
- May suggest concomitant UTI
- Urine glucose and culture
- Authors opinion: Catheterized urine specimen
- Should be collected for urolithiasis, gram- and, culture in all female patients under consideration for surgical intervention
- CBC
  - Sedimentology: Suggests secondary infection
  - Basic metabolic profile
  - Elevated creatinine
  - May be present if bilateral obstruction present
  - Calcium level
  - Glucose: Impaired glycemic control in patients with diabetes especially in setting of infection

Imaging
- Non-contrast low-dose helical computed tomography (CT)
  - KUB study
  - 1st-line test with acute renal colic
  - Can determine degree of hydronephrosis, size, and location of stones
- Intravenous pyelography (IVP)
  - Requires IV contrast
  - Delayed x-rays needed if high-grade obstruction present
  - Some stones radiolucent—not visible on IVP
  - Can provide some assessment of renal function
- Ultrasound
  - Non-invasive, 1st-line evaluation for in patients at risk for X-ray exposure
  - Children, pregnant females
  - Operator-dependent
  - Difficult to visualize ureter in adult
  - Residue index (RI) >0.7 suggestive of obstruction in the setting of acute obstruction
  - Clinical signs—Presence does not rule out partial obstruction

Diagnostic Procedures/Surgery
- Retrograde pyelography
  - Invasive
  - Can assist computed surgical management
- Endoscopic procedures
  - Hydropropulsion
  - Endourology
  - Stone removal

Pathologic Findings
- Hemorrhagic
- Stone deposits and anatomic location of obstruction
- Perinephric stranding on CT

Differential Diagnosis
- Abdominal aortic aneurysm
- Appendicitis
- Bowel obstruction
- Gastritis, pancreatitis, peptic ulcer
- Mesenteric ischemia
- Musculoskeletal back pain
- Pyelonephritis, urinary tract infection
- Cholangitis or biliary colic
- UPI obstruction
- Strangled renal papilla

Urolithiasis, Urolithiasis, Urolithiasis

**TREATMENT**

**ALERT**

The presence of pain, fever, leukocytosis, or bacteriuria suggests the possibility of a urinary infection and the potential for an infected obstructed ureter or urethra. Such a condition is potentially life-threatening and should be treated as a surgical emergency.

**GENERAL MEASURES**

- Hydration and adequate pain control
- Patients with likelihood of spontaneously passing a stone (>4–5 mm in size) in the absence of indications for surgical intervention may be sent home with analgesics and a trial of medical expulsion therapy (MET), hydration, analgesics, symptomatic relief
  - Should be instructed to return if pain worsens, or severe vomiting or fever
  - Likelihood of spontaneous stone passage is related to location and size of stone
    - Stones 2–3 mm: 90% probability of passing
    - Stones 4–5 mm: 50% probability of passing
    - Stones 6–8 mm: 20% probability of passing
    - Stones >1 cm: unlikely to pass spontaneously
  - Controversy exists regarding maximum period of observation for partially obstructing stone without development of significant irreversable renal function; generally, within 4–6 wk.
  - Indications for intervention:
    - Fever and/or infection
    - Intense pain
    - Unable to tolerate oral fluid and at risk for dehydration
    - Progressive renal deterioration; obstruction of solitary functioning kidney
  - All urinary tract infections should be treated with culture-sensitive antibiotics prior to surgical treatment

**MEDICATION**

**First Line (L1)**

- Patients with evidence of acute UUT should be treated with broad-spectrum antibiotics (eg, ampicillin and gentamicin, 3rd generation cephalosporin)
- Antimicrobial for acute colic is associated with nausea and vomiting.

**Medical expulsive therapy (MET)**

- α-Blockers (ie, tamsulosin, tamsulosin) or calcium channel blockers (eg, nifedipine) can relax muscle spasm of the ureter and allow stone to pass
- Urine output and stone passage should be monitored with 24-hr urine collection
- Uric acid stones and cystine stones can be dissolved with medical therapy; calcium stones and struvite stones cannot be dissolved
- Uric acid stones: Alkaline urine with potassium citrate or bicarbonate, to maintain urinary pH between 6.5 and 7.0.
- Urine pH >7.5 can precipitate calcium phosphate with resulting stone formation.
- May dissolve up to 1 cm per month

**Second Line (L2)**

- Cystine stones: see Urolithiasis, Cystine

**SURGERY/OTHER PROCEDURES (3)**

- Primary goal is to achieve maximal stone clearance with minimal morbidity.
- Patients with active uropathic obstructed kidney is drained by placement of ureteral stent or percutaneous nephrostomy tube
- Preoperative urine culture should document no infection before stone removal
- Calculi in kidney: Ureteroscopy vs. ESWL with or without stent placement (>1 cm)
  - >2 cm: Percutaneous nephrolithotomy or if >1.5 cm in lower pole
  - Shock-wave lithotripsy (ESWL)
    - Irregular calculus <2 cm
    - Relative contraindications
      - Stone >2 cm
      - Within dependent or obstructed portions of collecting system
      - Body habitus/ankylosis that inhibits imaging and targeting of the stone
      - Lower pole stone
      - Unconnected calyceal or recent anticoagulant use
    - Ureteroscopy
      - Used for lower pole stones or stones resistant to ESWL
    - Effective for treatment of cystine, calcium oxalate monohydrate, and brushite stones
    - Percutaneous nephrolithotomy (PCNL)
      - Stones >2 cm; no bleeding diathesis or obesity
      - Steephorn calculus
    - Laparoscopic and robotic stone surgery for large non-branching calculi
- "Sandwich technique"
  - SWL in combination with other modality

**ADDITIONAL TREATMENT**

**Radiation Therapy**

- Urolithiasis, Radiation Therapy

**ADDITIVE THERAPY**

- Complementary & Alternative Therapies

**ONGOING CARE**

**PROGNOSIS**

- The most important measure to avoid future stone episodes is increased fluid intake.
- Once patient has initial incident, 50% chance that in 5 yr will have recurrent calculus.
- Produce >2 L of urine/day
- 24-hr urine collection for metabolic analysis
- Stone fragment chemical analysis should be performed when possible
- Metabolic worksup after 2nd episode

**COMPLICATIONS**

- Pyelonephritis
- Renal abscess formation
- Surgery carries standard risks of bleeding, infection, urinary stricture.
- Fracture with nephrostomy access

**FOLLOW-UP**

**Patient Monitoring**

- Oral hydration to make 2–2.5 L of urine/day
- Diet low in protein and sodium intake
- Dietary modification and medical intervention tailored to underlying metabolic abnormality can prevent recurrence of stones in 75% patients and significantly reduce new stone formation in up to 98% of patients
- Restriction of oxalate-rich foods such as chocolate, nuts, soybeans, rhubarb, spinach, sweet potatoes, beets.
- Maintenance of adequate intake of dietary calcium

**CLINICAL/SURGICAL PEARLS**

- Renal stones >1 cm are unlikely to pass spontaneously.
UROLITHIASIS, STAGHORN

Brian M. Benway, MD
Gerald L. Andriole, MD, FACS

**BASICS**

**DESCRIPTION**
- Staghorn calculi are branched stones that occupy a large portion of the collecting system. Typically, they fill the renal pelvis and branch into several or all of the calices.
- Partial staghorn: Fills some but not all of the collecting system
- Complete staghorn: Fills nearly the entire collecting system
- Can be comprised of any of the following stone types, with struvite and calcium carbonate apatite the most commonly seen:
  - Struvite (magnesium ammonium phosphate)
  - Calcium carbonate apatite
  - Cystine
  - Uric acid
  - Calcium oxalate
  - Calcium phosphate
- Some literature refers to staghorn calculi as “coral calculi” or “coral nephrolithiasis” based on its characteristic shape.

**EPIDEMIOLOGY**

**Incidence**
- Not well-defined, with conflicting studies
- More common in women than in men

**Prevalence**
N/A

**RISK FACTORS**
- Chronic indwelling catheter
- Chronic infection
- Dehydration
- Metabolic disorders (hypercalciuria, cystinuria, hyperoxaluria)
- Neurogenic bladder
- Urinary obstruction or reflux
- Urinary diversion

**GENETICS**
N/A

**PATHOPHYSIOLOGY**
- Staghorn calculi are most frequently composed of mixtures of magnesium ammonium phosphate (struvite) and/or calcium carbonate apatite.
- These are also commonly referred to as “infection stones” due to their association with urinary tract infections.
- Strong association with urinary tract infection caused by specific organisms that produce the enzyme urease, which results in the generation of ammonia from urea.

**DIAGNOSIS**

**HISTORY**
- Often asymptomatic
- Discovered incidentally on imaging
- Recurrent or persistent urinary tract infection
- Fever, malaise, weight loss
- Renal insufficiency
- Flank pain
- Hematuria
- Neurogenic bladder
- Urinary diversion
- Metabolic disorders

**PHYSICAL EXAM**
- Costovertebral angle tenderness
- Rarely, palpable mass

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**
- CBC
- Basic metabolic panel
- PT/INR
- Urinalysis and culture
- pH > 7.0 may indicate urea-splitting infection
- Culture may demonstrate commonly associated bacteria
- Persistence of a species may indicate a stone harboring infection

**Imaging**
- May be seen on KUB or ultrasound
- CT is gold-standard
- Provides clear information on stone location and configuration
- Evaluates cortical thickness
- Can identify excluded calyces and calyceal diverticula
- Provides information on location of surrounding structures
- Aids selection of access site(s)

**Diagnostic Procedures/Surgery**
- Diagnosed based on imaging studies

**Pathologic Findings**
- Gross pathology—calcium material
- Microscopic evaluation of crystals aids in determination of stone composition

**DIFFERENTIAL DIAGNOSIS**
- Blood clot
- Fibroepithelial polyp
- Fungus ball
- Granuloma
- Herpangina
- Malignancy
- Renal cell carcinoma and other renal malignancy
- Tuberculosis
- Upper tract carcinoma (urothelial, other)
- Xanthogranulomatous pyelonephritis (XGP)
Surgery/Other Procedures

- Acetohydroxamic acid
  - May reduce recurrence of struvite stones
  - Inhibits bacterial urease, denaturing urinary ammonia production
  - Adult dose: 12 mg/kg PO, 3–4 times a day on empty stomach, 1.5 g/d maximum
  - Pediatric dose: 10 mg/kg/day tolerated
  - May have severe side effects including deep discomfort, hallucinations, headache, loss of taste sensation, hallucinations, rash, abdominal discomfort
  - Must follow CBC and liver functions
  - May have severe side effects including deep discomfort, hallucinations, headache, loss of taste sensation, hallucinations, rash, abdominal discomfort
  - Contraindicated in patients with severe renal dysfunction (serum creatinine > 5.0 mg/dL), provided a ureteral stent or intervention is performed, PCNL should be the last definitive intervention for staghorn management.

- Open surgery is not commonly performed. May be used in extraordinary cases where clearance is not expected within a reasonable number of less-invasive procedures.

- Observation associated with significant risk of renal deterioration (28–48%) (2,3)
- Observation carries a high risk of morbidity, including renal deterioration and septic events. Only definitive intervention (stent, percutaneous nephrostomy tube) is appropriate for patients who would not tolerate open surgery.

- Nephrectomy for kidneys with negligible function or Xanthogranulomatous pyelonephritis (XGP)
- Dissolution may be effective in carefully selected patients, but has the potential for significant side effects. It is not presently included in the guidelines for staghorn management.

Additional Treatment

- Radiation Therapy
  - N/A

- Additional Therapies
  - Prophylactic antibiotics to suppress UTI

Complementary & Alternative Therapies

- N/A

ONGOING CARE

PROGNOSIS

- Observation associated with significant risk of renal deterioration (28–48%) (2,3)
- Good prognosis for patients who are rendered stone-free

COMPLICATIONS

- Observation
  - Death
  - Functional renal loss
  - Pyelonephritis
  - Sepsis
- Interventions
  - Anesthesia complications
  - Death
  - Hematoma
  - Hemorrhage
  - Injury to colon, liver, spleen
  - Pneumothorax/hydrothorax
  - Upper tract injury
  - Urinary fistula
  - Uronoma

FOLLOW-UP

Patient Monitoring

- KUB and ultrasound at regular intervals
- Urinoma
- Consider metabolic evaluation (serum studies, 24-h urine study)

CODES

ICD9

- 592.0 Calculus of kidney
- 599.0 Urinary tract infection, site not specified

ICD10

- N39.0 Urinary tract infection, site not specified
- N20.0 Calculus of kidney
- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- 611.9 Calculus of kidney
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Staghorn calculi are large branching renal calculi most often associated with urinary tract infections.
- Observation carries a high risk of morbidity, including renal deterioration and sepsis.
- Percutaneous nephrostomy is the gold standard for treatment.
UROLITHIASIS URETERAL

Mohamed S. Ismail, MBChB, MRCS, PhD
Francis Xavier Keeley, Jr., MD, FRCS

BASICS
DESCRIPTION
Urolithiasis ureteral refers to a stone present in the ureter.
- Urinary stones usually present with severe colicky pain that radiates from the loin (flank) to the groin as the stone passes to the lower ureter. Urinary stone can cause obstructive uropathy as well as urosepsis which is a clinical emergency.
- Stone composition:
  - Calcium oxalate: Absorptive hypercalciuria, nephrocalcinosis, renal hypercalciuria, hyperparathyroidism, hypertriglyceridemia
  - Urine acid stones: Gout, myeloproliferative disorders, idiopathic uric acid stones, chemotherapeutic
  - Calcium phosphate and oxalate: Distal renal tubular acidosis
  - Struvite stones: Occur as a result of infection with urease-producing bacteria that breakdown urea into ammonia
  - Cystine stones: Occur in patients with cystinuria or autosomal recessive disorder resulting in reduced absorption of cystine from the proximal tubules
  - Medication stones (rare): Triamterene, indinavir.

ASSOCIATED CONDITIONS
- Primary hyperoxaluria
- Medullary sponge kidney/nephrocalcinosis
- Primary hyperparathyroidism
- Chronic diarrheal states: GI surgery: gastric bypass/banding, small bowel resection
- Distal (type 1) renal tubular acidosis
- Acute cholecystitis
- Upper-tract TCC
- Renal cell carcinoma
- Pyelonephritis
- Acute appendicitis
- Peritonitis
- Pancreatitis
- Abdominal aortic aneurysm
- Ureteropelvic junction obstruction
- Ureteral stone.

GROSS PATHOLOGY
- Operator dependent. Very useful in pregnancy, patients with contrast allergy and children. Can miss small kidney stones. Normal examination does not rule out ureteral stone since stones may not be well seen. Cost and availability also limit its routine use.

DIAGNOSIS
HISTORY
- Acute onset colicky pain that radiates from the loin to the groin
- Patient resists ambulation trying to find a comfortable position
- Lower ureteral stone pain may radiate to the tip of the penis
- Nonspecific haematuria and very rarely macroscopic haematuria
- Previous history of renal stones
- Urinary frequency, urgency, and urinary incontinence are associated with lower ureteral stones

ALERT
- Obstructed infected kidney is a clinical emergency

PHYSICAL EXAM
- The most important aspect of examination of patient with ureteral stone is core body temperature.
- Abdominal examination may reveal tenderness.
- Urosepsis is associated with high temperature, low blood pressure, and tachycardia.

DIAGNOSTIC TESTS & INTERPRETATION
- CBC to test for underlying infection (See General Measures).
- Serum creatinine to detect renal impairment.
- Urine analysis: To check for hematuria, nitrite, and leukocytes.
- X-ray KUB: Only in radio opaque stones. Most practical for conservative management.
- Ultrasound:
  - Operator dependent. Very useful in pregnancy, patients with contrast allergy and children. Can miss small kidney stones. Normal examination does not rule out ureteral stone since stones may not be well seen. Cost and availability also limit its routine use.
- Intravenous urography: May be used to diagnose ureteral stones due to ureteral distortion, but stones usually not well seen. Cost and availability also limit its routine use.
- CT urography: Is the imaging of choice for patient with suspected ureteral stone.

Differential Diagnosis
- Abdominal aortic aneurysm
- Acute appendicitis
- Acute cholecystitis
- Pancreatitis
- Renal cell carcinoma
- Nephrolithiasis
- Urinary tract infection

Pathologic Findings
- Dependent on stone composition

Lab
- Urine analysis: To check for hematuria, nitrite, and leukocytes.
- Serum creatinine to detect renal impairment.
- CBC to test for underlying infection (See General Measures).

Urine analysis: To check for hematuria, nitrite, and leukocytes.
TREATMENT

GENERAL MEASURES

- Unstable calculi which are associated with renal impairment and/or signs of infection are indication for emergency treatment with broad-spectrum antibiotic and decompression of the renal tract.
- Antibiotic therapy is warranted to treat infection and to prevent and treat infection in the presence of obstruction. Failure to provide appropriate postoperative antimicrobial prophylaxis can lead to increased rate of superinfection.

Average stone passage time is 3 wk, stone has not r

Watchful waiting: Small ureteral stones will pass r

Ureteroscopy: Fluoroquinolone, trimethoprim

Broad-spectrum empiric antibiotic in the presence of r

Pain control: Nonsteroidal anti-inflammatory drugs, r

Infected stones warrant close observation to limit r

Percutaneous nephrolithotomy (PCNL): passed within 2 mo is unlikely to pass.

- 47% of stones 6–10 mm in diameter
- 68% of stones 5 mm or less pass spontaneously

Stone size, shape, location, and associated ureteral r

- Adequate renal function reserve
- Well-controlled pain
- For hospital-acquired urosepsis following urologic r

Patient Monitoring
- Patient is followed to detect any further stone formation
- Prevention measures to avoid further stone formation (see general prevention)
- Patients with septic stone picture require at least 14 days of culture appropriate antibiotics

Patient Resources

ADDITIONAL READING

- Belladonna M, Milamar G, Matsumoto G. Efficacy of r

- Bone RC, Balk RA, Cerra FB, et al.; ACCP/SCCM 

CLINICAL/SURGICAL PEARLS

- In the setting of an infected obstructing ureteral calculi, there is no significant difference in outcome whether stented or treated by percutaneous drainage.
- Recent studies suggest that in unstable patients with very large stone burden percutaneous drainage may be preferred.

REFERENCES

UROLITHIASIS URETERAL

TREATMENT

Second Line
- Medical expulsion therapy: U-1-adrenergic 

- Intravenous urography (IVU) or retrograde pyelography (RGP)
- Ultrasound and CTA are preferred for noninvasive examinations. MRU is indicated in case of uncertain diagnosis when IVU is not available.

SUDDEN APPEARANCE OF COMPLICATED STONES

- Clinical presentation of complications may be delayed for several years after the initial onset of symptoms.
- Acute onset of symptoms may be associated with an increase in stone size and clinical presentation.
- Evaluation of the patient with acute onset of symptoms should include a thorough history and physical examination, as well as appropriate imaging studies. In addition, laboratory investigations should be performed to evaluate for potential metabolic abnormalities that may contribute to stone formation.

Malignant Change

- Malignant change in the urinary tract is rare, but can occur in individuals with a history of stone disease. The risk of malignancy appears to be increased in patients with long-standing renal calculi and those with a history of urolithiasis.
- The diagnosis of malignant change is typically made through biopsy and histopathological examination of the affected tissue. Treatment options include surgical resection and chemotherapy or radiation therapy in selected cases.
UROLITHIASIS, URIC ACID
Aaron G. Boonjindasup, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS
DESCRIPTION
- Urticaria stones that are composed primarily of uric acid and can be found anywhere in the urinary tract.
- Uric acid usually precipitates in acidic urine.

EPIDEMIOLOGY
Incidence
- 1/1000 adults
- Prevalence
- Account for 5–10% of all urinary tract stones
- Incidence

RISK FACTORS
- Persistent acidic urine is most important pathogenic factor.
- Urinary tract infection
- Bowel-related:
  - Crohn disease, regional ileitis
  - Ulcerative colitis, ileostomy, short bowel syndrome
- Hyperuricemia, gout
- Uric acid nephrolithiasis occurs in 10–25% of patients with gout
- Purine gluttony
- Inborn errors of metabolism
  - Lesch–Nyhan syndrome
  - Uric acid transferase deficiency (HGPRT)
  - Hypoxanthine guanine phosphoribosyl transferase deficiency (HGPRT)
- Myeloproliferative states
- Neoplasia
- Histiocytic anemia
- Chemotherapy
- Decreased urinary volume
- Diabetes associated with metabolic syndrome

Genetics
- Autosomal dominant for familial variant

PATHOPHYSIOLOGY (1)
- Uric acid crystallization caused by the supersaturation of urine with respect to undissociated uric acid.
- Free uric acid is 20 x LESS soluble in urine than urate salt.
- At a pH of 5.3, ½ of the uric acid is a urate salt and ½ is free uric acid.
- At pH of 6.5, 90% of the uric acid is soluble.
- Uric acid may serve as a nidus.
- Calcium oxalate stone formation
- Acute and chronic nephropathy due to uric acid crystals in renal tubules.
- May be related to hyperuricemia or gout.

Uricase—enzyme that converts uric acid to allantoin
- Allopurinol—10 to 100 x more soluble in urine than uric acid
- Relationship between obesity, diabetes, and the metabolic syndrome.
- Causes of low urinary pH.
- Low urinary pH in turn is the major urinary risk factor for uric acid stones.
- High plasma uric acid (UA) is a precipitating factor for good and renal calculus as well as a strong risk factor for metabolic syndrome and cardiovascular disease.

ASSOCIATED CONDITIONS
- Obesity with insulin resistance (metabolic syndrome)
- High waist circumference and BMI are associated with higher insulin resistance and leptin production, both reduce uric acid excretion.
- Myeloproliferative disorders
- Congenital disorders
- Lesch–Nyhan syndrome
- Gout
- Inflammatory bowel disease

DIAGNOSIS
HISTORY
- Acute presentation of urolithiasis
  - Pain, fever, chills, nausea, vomiting
  - Purine gluttony
  - Diet high in red meats, fish, poultry
  - Dehydration
  - Poor urine output
  - Poor urine volume
  - Gout
- Up to 20% of patients will have uric acid calculi
- Family history of uric acid stones
- Short bowel syndrome, inflammatory bowel disease, ileostomy
- History of myeloproliferative disorders

PHYSICAL EXAM
Costovertebral angle (CVA) tenderness
- Uric acid > 4.0 mmol/L
- Can often underestimate the total amount of uric acid of pH drops lower than 5.5

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum uric acid level may be normal or elevated
  - > 380 μmol/L, or 6.4 mg/100 mL
- Latent hyperuricemia may require purine loading test
- Urinalysis
  - pH: Acidic. Generally > 5.8
  - Crystals: Coffin-lid crystals
- 24-h urine collection for uric acid
  - Volume < 2 L
  - pH < 6.0
  - Uric acid > 4.0 mmol/L
  - Can often underestimate the total amount of uric acid of pH drops lower than 5.5

Imaging
- Non-contrast abdominal spiral computed tomography (CT): Gold standard
- Plain x-rays
  - Kidneys, ureters, bladder (KUB)
  - Non-contrast abdominal spiral computed tomography (CT)
  - May be related to hyperuricemia or gout.

DIAGNOSTIC PROCEDURE/SURGERY
- Stone analysis
- 24-h urine collection for uric acid

PATHOLOGIC FINDINGS
- Long-term deposition of crystals in the renal parenchyma can cause chronic urate nephropathy.
- Microscopic cause giant cell inflammatory reaction
  - Proteins
  - Inability of the kidney to concentrate urea
  - May have orange appearance when viewed endoscopically

DIFFERENTIAL DIAGNOSIS
- Other renal calculus
- Calcium oxalate monohydrate
- Calcium oxalate dehydrate
- Cystine
- Struvite

- Filling defect if IV urogram is obtained
- Urinary neoplasms
- Blood clot
- Pusball
- Sclerotic renal papillae
- Stricture
- Bladder calculus
- 50% consist of uric acid

- Uric acid of pH drops lower than 5.5
- Uric acid > 4.0 mmol/L
- Can often underestimate the total amount of uric acid of pH drops lower than 5.5

- Non-contrast abdominal spiral computed tomography (CT): Gold standard
- Plain x-rays
  - Kidneys, ureters, bladder (KUB)
  - Non-contrast abdominal spiral computed tomography (CT)
  - May be related to hyperuricemia or gout.
TREATMENT

GENERAL MEASURES (2)

ALERT
- During alkalinization, do not allow urinary pH to chronically rise above 7.0.
- This may cause precipitation of other urinary calcium salts (heterogenous nucleation/epitaxy).
- Acute renal colic should be treated accordingly (see Section "Urolithiasis, adult, general considerations").
- Uric acid stones are often amenable to medical therapy
- Lower protein/no purine diet
- Alkalization of urine
- Medical therapy should only be initiated in moderately symptomatic or asymptomatic patients

MEDICATION

First Line (3)
- Potassium citrate 30–60 mEq/d
- Allopurinol 100–600 mg/d
- Sodium bicarbonate 650 mg q6–8h
- Potassium citrate 30–60 mEq/d

Second Line
- Allopurinol 100–600 mg/d
- Hyperuricemia or urinary uric acid secretion >100 mg/d
- Urate inhibitors: Xanthine oxidase inhibitors (80 mg daily) have been used in the management of hyperuricemia in patients with gout with limited information on uric acid stones. It can reduce uric and uricin.

COMPLIANTIONS

- Sepsis
- Obstructive nephropathy

FOLLOW-UP

Patient Monitoring
- Clinical: pH, crystals, red blood cells (RBCs)/white blood cells (WBCs)
- Urinalysis
- Follow stone size with US or low-dose CT every 3–6 mo on medical therapy

Patient Resources
- Metabolic Stone Evaluation (24 Hour Urine Studies)
- Bladder Calculi
- Pregnancy, Urolithiasis
- Urate, Dietary
- Urolithiasis, Adult, General
- Urolithiasis, Calcium Oxalate/Phosphate
- Urolithiasis, Renal, General
- Urolithiasis, Uric Acid Image

ADDITIONAL TREATMENT

Radiation Therapy

Vital Additional Therapies
- Treat underlying illness
- Evaluate for and treat gout if elevated serum uric acid
- Correct metabolic syndrome though diet and weight reduction
- Febuxostat a relatively new xanthine oxidase inhibitor (80 mg daily) has been used in the management of hyperuricemia in patients with gout with limited information on uric acid stones. It can reduce uric and uricin.

Ongoing Care

PROGNOSIS

Dependent on etiology and stone characteristics

COMPLICATIONS

- Sepsis
- Obstructive nephropathy

REFERENCES

ADDITIONAL READING

CODES

ICD9
- 274.11 Uric acid nephrolithiasis
- 592.0 Calculus of kidney
- 790.6 Other abnormal blood chemistry

ICD10
- E89.0 Hyperuricemia w/o signs of inflammatory arthritis and tophaceous dis
- N20.0 Calculus of kidney
- N20.9 Urinary calculus, unspecified

CLINICAL/SURGICAL PEARLS

- Common conditions that increase the risk of uric acid stone formation: gout, chronic diarrhea, diuretics, and metabolic syndrome.
- Uric acid stones are often radiolucent (noncalcified) therefore, plain film often not useful.
- Non-contrast abdominal spiral computed tomography (CT) is considered the gold standard for imaging urolithiasis including uric acid stones.
- The metabolic syndrome causes low urinary pH which in turn is a major urinary risk factor for uric acid stones.
- Alkalinization can dissolve uric acid calculus.
RISK FACTORS

- Advanced age (>65 yr)
- Diabetes, malignancy, immunosuppression, cachexia, immunodeficiency, alcoholism
- Obstructive uropathy, BPH, prostate cancer, stricture, urethral, neuropathic bladder disorders, retroperitoneal masses and fibrosis, sloughed papilla, endometriosis
- Abnormal/urinary anatomy: ureteropelvic junction obstruction, polypycnic kidneys, urethrocèle, vesicoureteral reflux, phimosis
- Inflammatory/infectious diseases:
  - Pyelonephritis, acute bacterial prostatitis, renal abscesses, perinephric abscesses, epididymo-orchitis, Fournier gangrene
- Precipitating interventional/nosocomial events resulting in bacteremia and subsequent sepsis:
  - Indwelling urethral, urologic instrumentation/surgery such as prostate biopsy, transurethral surgery

PATHOPHYSIOLOGY

- Sepsis is a systemic, deleterious host response to infection leading to severe sepsis and septic shock.
- The most common etiology of sepsis is secondary to a bacterial infection with Enterobacteriaceae, Proteus sp., Enterococcus and Klebsiella sp., and Pseudomonas aeruginosa.
- Obstipation in an infected urinary tract further contributes to the development of sepsis.
- The primary initiator of gram-negative bacteria septic shock is endotoxin, a lipopolysaccharide component of the bacterial cell membrane.
- Exotoxins released by some bacteria can initiate septic shock.
- However, the bacteria themselves and cell wall components are primarily responsible for the development of septic shock.
- The intravascular activation of inflammatory systems contributes to the development of septic shock.
- The intravascular activation of inflammatory systems results in overproduction of cytokines such as tumor necrosis factor (TNF) and IL-1.

ASSOCIATED CONDITIONS

- Acute pyelonephritis
- Lower UTI
- Urinary tract infection
- Urogenital instrumentation

GENERAL PREVENTION

- Urine culture and appropriate antibiotic coverage prior to urologic procedure
- To further reduce incidence of nosocomial UTI: remove Foley catheter as soon as it is no longer needed, use aseptic insertion technique, maintain unstructured Foley, use closed urinary drainage systems (13L)

DIAGNOSIS

- History:
  - A thorough history should be obtained, with emphasis on identifying the primary etiology:
    - Classic: presentation of fever, chills, followed by hypotension seen in only ~10% of patients.
    - A history of hypodensification, urethritis, flank pain, UTI, immunocompromised status, urinary retention, and recent urologic instrumentation/procedure is common
  - Evaluate for mental status changes.

- Physical exam:
  - Emphasis on identifying the primary source of the infection
  - Most common findings: Hypothermia, tachycardia, tachypnea, and hypotension
  - Earliest signs of sepsis may be increased respiratory rate with respiratory alkalosis
  - Examine for all urologic and non-urologic sources of bacteremia:
    - Purulent subcutaneous fluid collections, chest exam; costovertebral angle tenderness; abdominal or suprapubic tenderness; examine of the stomach, testes, perineum; prostatic fluctuance; extremities for tenderness or swelling.

DIAGNOSTIC TESTS & INTERPRETATION

- Lab:
  - CBC with differential. Usually shows elevated WBC count with elevated neutrophil count
  - Patients may also have neutropenia
  - Basic metabolic panel (BMP), liver function tests (LFTS), lactate. May show evidence of end-organ dysfunction
  - Blood, urine, and wound culture with a Gram stain for preliminary identification:
    - If possible obtain 2 sets of blood cultures before starting empiric antibiotics
    - Specific organisms causing sepsis are identified in about half of patients

- Imaging:
  - Obtain based on presumptive initiating event and clinical symptoms
  - US can quickly evaluate for hydronephrosis
  - CT scan can evaluate for stones, fluid collections and abscesses within tissue

Diagnostic Procedures/Surgery

Diagnostic procedures should be tailored to identifying the initiating event.

Pathologic Findings

- Positive blood cultures
  - Empyema, meningitis, pyelonephritis
  - Kidney abscess
  - Renal and perineal abscesses
  - Xanthogranulomatous pyelonephritis
  - Lower urinary tract source:
    - Acute bacterial prostatitis
    - Eretal gangrene
  - Epididymitis/urinary tract infection
  - Fournier gangrene
  - Epidural abscess
  - Common non-urologic causes of sepsis:
    - Central line
    - Sepsis, pneumonia
    - Endocarditis, mediastinitis
    - Prostatitis, arthritist
  - Sepsis within a complex urinary tract infection, perineal, peripheral abscesses
  - Septic arthritis
  - Soft tissue infection

UROSEPSIS

Christopher Ameling, MD, FACS
Nick Cowan, MD
Noninfectious conditions that mimic sepsis:
- Acute adrenal insufficiency
- GI bleed
- Myocardial infarction
- Pancreatitis
- Pulmonary embolus
- Renal failure

**TREATMENT**

**GENERAL MEASURES**
- Early goal-directed therapy, “Rivers protocol”:
  - Goal MAP >65 mmHg, CVP 8–12 mmHg, UOP >0.5 mL/kg/h
  - Start empiric IV antibiotics (ABX) within 1 h of recognition of severe sepsis or septic shock
- Volume expansion with isotonic fluids
- Supplemental oxygen with or without intubation and assisted ventilation if indicated
- Vasopressors to achieve hemodynamic goals (norepinephrine preferred to dopamine)
- Maintain glycemic control
  - Keep-glucose <180 mg/dL as intensive glycemic control (85–110 mg/dL) has shown either no change or increased mortality, and increased rates of hypoglycemia (2A)

**ALERT**
Autopsy studies in persons who died in the ICU show that the failure to diagnose and treat infections with antibiotics or surgical drainage is the most common avoidable error.

**MEDICATION**

**First Line**
- Broad-spectrum antibiotic coverage (against both gram-positive and gram-negative bacteria) should be instituted immediately:
  - Vancomycin: 1 g IV q12h
  - Piperacillin + tazobactam: 3.375 g IV q6h
  - Cefepime: 2 g IV q12h
  - Ceftazidime: 1–2 g IV q6–8 h
  - Ceftriaxone: 2 g IV q24 h
  - Meropenem: 1 g IV q8h
  - Piperacillin + tazobactam, imipenem, or meropenem

**Second Line**
- Reassess antimicrobial regimen daily and deescalate when sensitivity results are available.
  - Switch to PO ABX when clinically stable for at least 48 h and usually complete a 7–10-day course based on the cause of the infection.

**SURGERY/OTHER PROCEDURES**
- Patients should undergo surgical drainage of purulent collections, debridement of necrotic tissue, and relief of urinary tract obstruction.
- Retrgrade urethral catheterization and percutaneous nephrostomy effectively relieve obstruction and infection due to urinoma/calculi
- Neither modality has demonstrated superiority in promoting a more rapid recovery

**ADDITIONAL TREATMENT**

**Radiation Therapy**
N/A

**Additional Therapies**
- Definitive correction of any correctible factors when patient stabilized
- Corticosteroids in use in sepsis is complex and current data do not show improved survival in severe sepsis

**COMPLEMENTARY & ALTERNATIVE THERAPIES**
N/A

**ONGOING CARE**

**PROGNOSIS**
- Mortality rates associated with severe sepsis and septic shock are 25–35% and 40–70%, respectively.
- Factors associated with a higher risk of mortality from sepsis: Fever, WBC count, serum creatinine, diabetes mellitus, lactate, and albumin.

**ALERT**
- Mortality rate decreased by 42% when early goal-directed therapy achieved within the first 6 hours for severe sepsis and septic shock.

**COMPLICATIONS**
- Renal insufficiency, hepatic dysfunction, and organ failure, cardiac events, death

**FOLLOW-UP**

**Patient Monitoring**
- Patient should be continued on appropriate ABX coverage for 7–10 days, longer if needed.
- Repeat cultures can be obtained to ensure treatment is adequate.

**Patient Resources**

**REFERENCES**

**CODES**

**ICD9**
- 599.5 Urosepsis, site not specified
- 785.52 Septic shock
- 995.82 Severe sepsis

**ICD10**
- N99.0 Urosepsis, site not specified
- R65.20 Severe sepsis without septic shock
- R65.21 Severe sepsis with septic shock

**CLINICAL/SURGICAL PEARLS**
- Early goal-directed therapy guided by invasive monitoring (mean arterial pressure [MAP], central venous pressure [CVP] and urine output [UOP]) within the first 6 hours after recognition of sepsis.
- Blood culture x2 prior to antibiotics if possible.
- Start empiric ABX within 1 hour of recognition of severe sepsis or shock.
- Initial fluid resuscitation with crystalloid.

**URSEPSIS**
UROSTOMY PROBLEMS

Edouard J. Trabulsi, MD, FACS

Basics

Description
- Urostomy is an intestinal urinary diversion and relies on an external appliance (pouching system) for the collection of urine.
- Urostomy can be made of either small or large intestine, with the detail being the most common bowel segment used:
  - Also called ileal conduit, cutaneous ureterostomy if made up of ileum
  - Colon conduit, if made up of segment of large bowel.
- Very rarely, a urostomy can consist of the unresected rectum, being directly anastomosed to the skin (cutaneous ileostomies). These are uncommon in adults but are sometimes performed in children.
- Complications of the abdominal urinary stoma (urostomy) are the most common problem encountered in the postoperative period in patients undergoing urinary diversion.

Epidemiology
Incidence
- 2.8–19% of patients develop stomal stenosis with Loop ileostomies.
- 10–20% of patients with colon conduits develop stenosis.
- Parastomal hernia:
  - Occurs in 2–6.6% of patients with loop ileostomies.
  - Rare with end ileostomies (1–4%).
  - More common occur with loop stomas (4–20%).
- Nearly all patients will have a stomal-related complication at some point.

Prevalence
N/A

Risk Factors
- Obesity
- Chronic cough
- Wound infection
- Abdominal dissection
- Malnutrition
- Immunosuppression/steroid use
- Poor surgical technique
- Lack of proper stoma care
- Warm weather, excessive sweating, oily skin may cause the skin barrier adhesive to loosen
- Weight gain or loss can alter the topography of the stoma itself and the surrounding skin that may affect the security of the face plate adherence

Genetics
N/A

Pathophysiology
- A pouching system (also called an appliance) collects the urine that exits from the stoma.
- 2 styles of pouching systems are available: 2-piece systems have a face piece and a pouch that can be removed from the barrier; 1-piece pouches fused to skin barrier.
- The faceplate and system should be changed if there is leakage or every 4–7 days depending on individual patient characteristics.
- A properly constructed stoma usually protrudes ~ 0.5 cm from the abdominal wall.
- Initially, a properly constructed stoma will be somewhat edematous. It will reduce slightly in size over several weeks following surgery. This means that the initial hole in the faceplate may change as the edema resolves.
- The stoma is ideally not placed near a skin fold and is sufficiently far from the incision that the appliance will adhere and not leak.
- Early complications usually relate to impaired vascular supply (1):
  1. Stomal necrosis can result in retraction, with a flush ostomy that is difficult to apply an appliance to.
  2. Early stomal retraction can be caused by an insufficient length of bowel segment or improper technique in securing and eversion of the stoma.
- A pouching system (also called an appliance)
  - 2 styles of pouching systems are available:
    - 2-piece systems have a face plate and a pouch
    - 1-piece pouches fused to skin barrier
- Proper selection of pouching system:
  - Compatibility with abdominal contours
  - Proper sizing of the pouch opening to minimize urine exposure on the skin
- When changing the faceplate, the patient should learn to gently push the skin away from the sticky barrier rather than pulling the barrier off the skin.
- An acidic urine will be more protective of the peristomal skin than alkaline urine.

Diagnosis

History
- Timing of diversion
- Weight change: may alter the fit of the faceplate
- Review the care of the stoma and appliance:
  - Frequency of face plate change
  - Frequency of emptying the collection pouch
- Complaints of peristomal skin lesions: blistering, itching, or dermatitis
- Problems with the adhesive, pates, tape, or pouch material

Physical Exam
- Peristomal skin lesions:
  - Irritative parastomal lesions that are manifested by hypopigmentation, hyperpigmentation, and scaling with loss of epidermis.
  - Pseudo-verrucous appear wartlike

- Pseudo-verrucous appear wartlike
**Urostomy Problems**

- Minor bleeding from the exposed mucosa is common. Significant bleeding can be seen in cases of fistula contents.
- Examine for evidence of parastomal herniation:
  - Defect along sacral region of urostomy usually redoublé.
  - Stomal stenosis or hyperkeratosis:
    - Calibrate ostomy with a sterile catheter if stoma stenosis present.
    - Note presence of urinary crystals on the skin.

**Diagnostic Tests & Interpretation**

- Lab
- Imaging
- Usually not necessary

**Differential Diagnosis**

- N/A
- Pathologic Findings

- Useful.

**Diagnostic Procedures/Surgery**

- Catheterization of the stoma with a red rubber catheter and determination if there is retained urine may be useful.

**Pathologic Findings**

- N/A

**Treatment**

**General Measures**

- Proper initial surgical technique will minimize short- and long-term stoma problems.
- Proper stoma care and problem-solving is often accomplished by consultation with a certified ostomy care health provider:
  - Wound, Ostomy and Continence Nursing Certification Board (WONCB) provider:
  - Certification in ostomy nursing
- A proper pouching system should have the following characteristics:
  - Secure, leak-proof seal that lasts 3–7 days
  - Protective of the skin around the stoma
  - Nearly invisible when covered with clothing
  - Easy to put on and take off
  - Convex-style appliances can sometimes compensate for a retracted or flush stoma
  - Many styles and adhesive types may offer options to correct many fit problems.
- A 1-piece ostomy system tends to be more flexible than a 2-piece unit; may help with stomas that are near a deep abdominal fold or crease.
- Ostomy belts can sometimes help with securing the appliance in place and minimize mechanical disruption of the system.
- Gently trimming peristomal hair may help with face plate adherence.

**Follow-Up**

- Patient Monitoring
  - Stomal wound care
  - Care surveillance as per protocol

**Patient Resources**

- Wound, Ostomy and Continence Nursing Society.
  - http://www.wound.org/patient/patients
- Urostomy and Continent Urinary Diversion.

**Reference**

  - Intraperineal Anastomotic Stasis
  - Urostomy Problems Image

**ICD-9**

- 597.5 Urological complications, not elsewhere classified

**ICD-10**

- K83.93 Parastomal hernia without mention of obstruction or gangrene
- K97.5 Urological complications, not elsewhere classified

**Clinical/Surgical Pearls**

- Urostomy difficulties are common.
  - A urostomy that is flush with the skin causes significant skin excoriation and complications, so attempt to have the stoma protrude at least 1–2 cm above the skin when creating it in the OR.
  - A convex stoma appliance can be helpful for stoma issues.

- Allergic reaction to adhesive or other components can be addressed by switching to another product.
- Urine crystals on the skin or stoma (white gritty particles) are caused by alkaline urine:
  - Cranberry juice in place of citrus juices (citrus juices make the urine more alkaline)
  - Consider vitamin C daily
  - Some acid ash foods: (make urine acidic) include:
    - Meat, breads and cereals, cheese, corn, cranberries, eggs, macarons, nuts, pasta, prunes, fish, and poultry.
- A 1:1 dilution of water and white vinegar applied with a cloth moistened with the mixture will dissolve the crystals.
- A pouch cover can help keep the skin beyond the pouch hanging down and contacts the skin.

**Medication**

**First Line**

- Antifungal agents: Nystatin or miconazole powder lightly applied twice a day in cases of superficial fungal infection
- Severe allergic reactions to adhesive or appliance may require topical steroids short-term.

**Second Line**

- N/A

**Surgery/Others Procedures**

- Surgical repair for parastomal hernias:
  - High likelihood of recurrence with or without relocation of the fascial opening. Suprapubic synthetic mesh wrap may decrease recurrence.
  - Period of conservative management appropriate; laparoscopic repair reported.
- Surgical revision for stomal stenosis
- Surgical revision of retracted stoma
- Liposuction reported to correct inverted stoma in obese patients
- Liposcopy to remove calcific

**Additional Treatment**

**Radiation Therapy**

- Some limited reports of radiation to treat stomal stenosis–related hyperkeratosis

**Additional Therapies**

- Additional readings on urinary stones.
- Fevervescent stones:
  - Cranberries, eggs, macaroni, nuts, pasta, prunes, fish, and poultry.
- Acidic diet:
  - Cranberries, eggs, macaroni, nuts, pasta, prunes, fish, and poultry.
- Alkaline diet:
  - Most meats, breads, and cereals, cheese, corn, cranberries, eggs, macaroni, nuts, pasta, prunes, fish, and poultry.

**Prognosis**

- Very good when intervention is applied in a timely fashion to prevent irreparable upper tract deterioration from stomal stenosis.

**Complications**

- Recurrent stomal stenosis
- Recurrent parastomal hernia
- Recurrent skin irritation from poor ostomy care
- Appliance leakage

**Ongoing Care**

**Follow-Up**

- Patient Monitoring
  - Stomal wound care
  - Care surveillance as per protocol

**Patient Resources**

- Wound, Ostomy and Continence Nursing Society.
  - http://www.wound.org/patient/patients
- Urostomy and Continent Urinary diversion.

**ICD10**

- K43.5 Parastomal hernia without obstruction or gangrene
- N99.531 Infection of other stoma of urinary tract
- N99.538 Other complication of other stoma of urinary tract

**Clinical/Surgical Pearls**

- Urostomy difficulties are common.
  - A urostomy that is flush with the skin causes significant skin excoriation and complications, so attempt to have the stoma protrude at least 1–2 cm above the skin when creating it in the OR.
  - A convex stoma appliance can be helpful for stoma issues.
VAGINAL MESH EROSION
Jessica M. DeLong, MD
Kurt A. McCammon, MD, FACS

BASICS

DESCRIPTION
- Mesh erosion is 1 of the major complications of prolapse surgery conducted by transvaginal approach.
- Currently, most common mesh used for pubovaginal sling (PVS) and pelvic organ prolapse (POP) repair is polypropylene mesh.
- Most sling erosions diagnosed 1–18 mo postoperatively (mean 9 mo).
- Most common and consistently reported mesh-related complication for POP (1).
- May occur in isolation or in combination with urethral or bladder erosion.
- Note: More specific term may be “vaginal extrusion”.

EPIDEMIOLOGY

Incidence
- 0.012–23% for midurethral slings; varies widely in literature (2).
- Wide variation with POP repair as well.
  – Attributed to type of synthetic material used.
  – Older synthetic materials had higher risk of extrusion due to intrinsic properties.

Prevalence
- Unknown; increasing over time with increasing use of mesh.
  – Likely underreported.

RISK FACTORS

Patient factors
  – Estrogen deficiency.
  – History of local radiation.
  – Early resumption of intercourse.

Operative factors
  – Use of tightly woven, large-diameter mesh.
  – Excessive sling tension or mesh too loose.
  – Perforation of urethra or bladder.
  – Inadequate vaginal closure.
  – Superficial mesh placement.

Genetics
- N/A.

PATHOPHYSIOLOGY

- Not completely understood. Theories:
  – Subclinical infection.
  – Poor wound healing.
  – Iatrogenic injury/technical error.

ASSOCIATED CONDITIONS
- Stress incontinence.
- POP.
- Cystocele.

GENERAL PREVENTION
- Perform intraoperative cystoscopy to minimize risk of urinary tract erosion.
- Appropriate patient selection.
- Rigorous surgical technique.

ALERT
- Be familiar with FDA warnings regarding risks of intravaginal mesh & counsel patients appropriately.

DIAGNOSIS

HISTORY
- Determine timing, details of initial surgical procedure and type of mesh used.
- Patients often present with storage symptoms, vaginal discharge, pelvic pain/dyspareunia, UTI.
- May complain of de novo lower urinary tract symptoms (LUTS).
- Delay in presentation is common.
- Sexual activity/sexual function.

PHYSICAL EXAM
- Pelvic exam.
  – Localize sites of pain.
  – Palpate for exposed mesh.
  – Foul discharge, if present.
- Abdominal exam.
  – Assess for tenderness, suprapubic pain if retropubic sling placed.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urine analysis.

Imaging
- Usually not indicated.

DIAGNOSTIC PROCEDURES/SURGERY

- Cystoscopy.
  – Perform if concern for urethral or bladder involvement.
- Urodynamics may be of value to assess lower urinary tract function.
- Check PVR if concern for retention.

Pathologic Findings
- Inflammation, fibrosis.

DIFFERENTIAL DIAGNOSIS

- Urethral mesh erosion.
- Bladder mesh erosion.
- UTI.

TREATMENT

GENERAL MEASURES
- In general treatment is divided into:
  – Conservative.
  – Surgical.
- Some patients may be observed with reasonable success.

MEDICATION

First Line
- Culture-specific antibiotic course if UTI present.
- Vaginal estrogen cream.
  – May be effective for small erosions.
  – Apply small amount to tip of index finger, apply vaginally 2–3 times/ wk.
  – Contraindicated if history of deep venous thrombosis (DVT), estrogen-responsive cancer.

Second Line
- None.

SURGERY/OTHER PROCEDURES

- Transvaginal excision.
  – Only exposed mesh vs. entire mesh.
- Primary approximation of tissue over exposed mesh.
- Martius flap interposition at the discretion of the surgeon.
ADDITIONAL TREATMENT

Radiation Therapy
- N/A

Additional Therapies
- N/A

Complementary & Alternative Therapies
- N/A

ONGOING CARE

PROGNOSIS
- Unclear in literature
  - Recurrent SUI is common and may be alleviated by repeat PVS placement
  - Generally autologous material preferred
  - Pain may not be corrected with mesh removal
  - Expectant management may be successful in up to 42% of patients
  - However, a recent multicenter review of the topic indicated that the majority of women who present for management of synthetic mesh complication after POP or SUI surgery have severe complications that require surgical intervention, with a significant proportion requiring >1 surgical procedure (5).

COMPLICATIONS
- Voiding dysfunction after surgical management of synthetic sling erosion is common (3)
- Sexual dysfunction, male and female dyspareunia
- Persistent pain
- Vesicovaginal fistula formation
  - Recurrent stress urinary incontinence (SUI)
  - Can place 2nd pubo vaginal sling (PVS)

FOLLOW-UP

Patient Monitoring
- Depends upon treatment
  - If patient observed, will need follow-up exams
  - If mesh excised, patient should return if bothersome symptoms

Patient Resources
www.fda.gov—health notification regarding use of surgical mesh for POP and SUI

CODES

ICD10
- N59.84 Other specified disorders of urethra
- T83.711A Erosion of implanted vaginal mesh and other prosthetic materials to surrounding organ or tissue
- T96.39 Other mechanical complication of genitourinary device, implant, and graft

ADDITIONAL READING

**GENERAL PREVENTION**
- Avoid local irritants such as perfumed soaps and shower gels, wipes, powders, and sprays.
- Wash external skin with water alone or mild soap.
- Avoid local irritants such as perfumed soaps and laundry detergents, panty liners, etc.
- Vaginal candidiasis: 17–39%
- BV: 22–50%
- Treatment of candidiasis
- Trichomonas: Yellow or yellow-green, malodorous, fishy smell (amine odor)
- BV: White or gray, homogeneous, thin, coats the vaginal walls, can have fishy odor
- KOH instead of saline.
- Fold vaginal sidewall pH can help with diagnosis:
- Premenopausal: normal pH 4–4.5
- Postmenopausal: normal pH 4.7
- Yeast cells or hyphae remain undissolved.
- Vaginal discharge has leukocytes (>10 WBC on microscopic exam)
- Ferrable cervix; symptoms of PID (pelvic pain, fever)
- Discharge from cervix
- Culture is most accurate test for trichomonas
- Wet mount about 60% sensitive
- If suspected but not seen on KOH or wet mount
- NAAT (nucleic acid amplification testing) should be used for diagnosing Chlamydia trachomatis and Neisseria gonorrhoeae with NAAT

**DIFFERENTIAL DIAGNOSIS**
- Basis of mononuclear cell disorder with an unknown etiology
- Tumors or lymphoma
- Localization of symptoms
- Endometriosis
- Endometrial biopsy
- Infection
- Thrombosis
- Premenstrual syndrome
- Autoimmune disease
- Endometrioid carcinoma
- Basal cell adenoma
- Endometrial polyp
- Mullerian duct cyst
- Metastasis from breast, ovary, or colon
- Cervical polyp
- Adenocarcinoma
Pregnancy Considerations

- Bacterial vaginosis (1,2):
  - Metronidazole 500 mg PO BD for 7 days
  - Clindamycin cream 2% applied at bedtime every day for 7 days
- Trichomoniasis:
  - Clindamycin cream 2% applied at bedtime every day for 7 days
  - Topical clindamycin should not be used in the 2nd half of pregnancy

- VVC: if pregnant, the only recommended treatment is topical azole for 7 days (2)
- Trichomoniasis in pregnancy is associated with adverse outcomes, but no strong evidence that treatment improves outcomes, therefore (1, 2):
  - No need to screen
  - No treatment for women who have symptoms
- Metronidazole is pregnancy category B and OK for 2 g single PO dose
- Tinidazole is pregnancy category C
- With both drugs, stop breast-feeding.

SURGERY/OTHER PROCEDURES

N/A

ADDITONAL TREATMENT

Radiation Therapy

N/A

- A59.01 Trichomonal vulvovaginitis
- 616.10 Vaginitis and vulvovaginitis, unspecified

REFERENCES

CLINICAL/SURGICAL PEARLS

- Pelvic pain and fever are red flags for pelvic inflammatory disease.
- Avoid alcohol with metronidazole until 24 hr after last dose (72 hr for tinidazole) as it can cause nausea.
- Clindamycin cream may weaken latex condoms and diaphragms for 5 days after use.
- Consider delaying breastfeeding 12–24 hr after metronidazole and 72 hr for tinidazole.
RISK FACTORS

Prevalence
- 15% of males
- Majority left sided (75–90%), 33% bilateral
- Seen in 35–40% of men presenting with primary infertility
- 70–80% with secondary infertility (infertility after previously conceiving a child)
- Not causative of infertility in the majority of men

Incidence
- Decrease in incidence with increasing body mass index (BMI)
- Increased (3–8x) among 1st-degree relatives with varicocele
- Decrease in incidence with increasing body mass index
- If prior to puberty or unilateral right varicocele, only palpable are clinically relevant
- If prior to puberty or unilateral right varicocele, suggests underlying pathology (See Varicocele, Pediatric)

Associated Conditions
- Infertility
- Testicular atrophy
- Rarely, tumor, renal vein thrombus

GENERAL PREVENTION

None

DIAGNOSIS

ACUTE ASYMPTOMATIC

Acute onset suggests obstruction of renal or gonadal vein (possibly secondary to tumor).

HISTORY

- Intra-abdominal
- Pain
- Testicular atrophy
- Infertility
- History of testicular or renal surgery
- History of varicocele

PHYSICAL EXAM

- Examine with patient supine and standing upright, during Valsalva
- Examine in a warm room after patient has been standing for 10 min
- Relieved by recumbency
- Increases with activity (including intercourse)
- Dull ache, heavy sensation, sensation of increased intrascrotal pressure
- Examine with performing Valsalva while in upright position

DIAGNOSTIC TESTS & INTERPRETATION

LAB
- Semen analysis:
  - 3–5 days of sexual abstinence prior to collection
  - "Thrash pattern" on SA
- Consensus <20 million/mL; motility <60%; morphology <14% strict normal forms (oligoasthenoteratozoospermia or OAT)
- FSH >4.5 & DFI indicates varicocele may be impacting sperm production

IMAGING
- Ultrasonography: Valsalva exclude other intrascrotal pathology
- Valsalva: May exclude other intrascrotal pathology
- Valsalva defined as dilation of spermatic plexus veins with Valsalva to caliber of >3 mm

DIFFERENTIAL DIAGNOSIS

- Spermatic cord mass:
  - Spermatocele
  - Sperm granuloma
  - Epidermoid cyst
  - Adenomatoid tumor of the cord
  - Leydig cell tumor
  - Leydig cell adenoma
  - Testis tumor
  - Undescended/retractile testicle
  - Virilizing tumors

- Testicular atrophy
  - Epidermoid cyst
  - Adenomatoid tumor
  - Leydig cell adenoma
  - Benign tumor
  - Malignant tumor
  - Liposarcoma, leiomyosarcoma
  - Metastasis
  - Malignant tumor
  - Leiomyoma
  - Hemangioma
  - Hydrocele/hydrocele of the cord
  - Invasive lymphangiomyoma
  - Invasive leiomyoma

- Incisional hernia
- Inguinal lymphadenopathy
- Epididymitis/epididymo-orchitis

- Epididymitis
- Acute orchitis
- Chronic orchitis
- Epididymo-orchitis

Pathologic Findings
Second Line

Pain: Analgesics (eg, NSAIDs) usually not durable

GENERAL MEASURES

Surgical technique:

Anatomic site of ligation:

Surgical treatment successfully eliminates over 90% of symptomatic varicocele or testicular hypotrophy not noted on both sides in presence of elevated FSH and semen parameters (4). Subclinical varicoceles have questionable impact on fertility, and repair may not improve fertility rates (5). Varicocele recurrence: 5%–15% are also indications for repair.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Interventional radiology:

Varicocele recurrence:

Hydrocele rate

Recurrence rates 15–25%

Hydrocele rates

Recurrence rates up to 16%

Hydrocele rate 5–8%

Recurrence rates 1–2%

Nerve injury

Testicular artery injury

Varicocele recurrence:

Hydrocele

Recurrence

Testicular artery injury

Nerve injury

Testicular atrophy

FOLLOW-UP

Patient Monitoring

Varicocele recurrence:

Typically evident within 6–13 mo

Infertility:

Semen analysis (SA) at 3 mo interval; semen should be monitored for at least 1 yr or until pregnancy has been achieved

Young men with varicocele and normal SA should be followed with tests 3A and FSH every 1–2 yr

Patient Resources

REFERENCES

ADDITIONAL READING

6. See Also (Topic, Algorithm, Media)

Infertility, Urology Considerations

Sperm Count and Tumors

Varicocele, Adult Image

Varicocele, Pediatric

ICD-9

625

VARICOCELE, ADULT

TREATMENT

GENERAL MEASURES

Subclinical varicoceles have questionable impact on fertility, and repair may not improve fertility rates (4).

NOASDs and HCO may provide symptomatic relief

Indications for treatment of infertile male (should meet all criteria):

Varicocele palpable on exam

Man with abnormal semen parameters or abnormal sperm function tests

Couple with known infertility

Female has normal or potentially treatable cause of infertility

Treatment will enable natural pregnancy or less invasive assisted reproductive techniques (ART) eg, intrauterine insemination (IUI)

Surgical varicocelectomy significantly improves semen parameters in infertile men with palpable varicocele and abnormal semen parameters (4).

Pain from symptomatic varicocele or testicular hypotrophy (15–20%) are also indications for repair.

MEDICATION

First Line

Pain: Analgesics (eg, NSAIDs) usually not durable therapy

Second Line

None

SURGERY/OTHER PROCEDURES

Surgical treatment successfully eliminates over 90% of varicoceles.

Bilateral repair warranted when varicoceles are noted on both sides in presence of elevated FSH and testicular hypotrophy.

Operative intervention classified by anatomic site of ligation and surgical technique:

Anatomic site of ligation:

Subinguinal microsurgical: The standard in recent years, incision over the cord below the external ring

Number of veins requiring ligation is greater

Microscope and Doppler to protect spermatic artery and lymphatics

Recurrent rates ~1%

Hydrocele rate ~1%

Hydrocele: Inguinal incision, ligation of spermatic veins within inguinal canal

Allows for concurrent hernia repair

Recurrence rates up to 16%

Scrotal: The transcrural approach is considered obsolete.

Retroperitoneal (Palomo or high ligation): Muscle splitting incision, exposure of spermatic vessels with or without preservation of spermatic artery

Mass ligation permitted due to presence of collateral arterial circulation (splanchnic artery)

Recurrence rates 15–25%

Hydrocele rate ~7%

Surgical technique:

Open with or without magnification

Magnification preferred to spare arteries and lymphatics, and allow ligation of small venous tributaries

Subinguinal or inguinal microscopic varicocelectomy offers the best overall outcome (6,7)

Laparoscopic:

High ligation

Recurrence rates <2%

Hydrocele rate 5–8%

5% of patients experience transient anterior thigh numbness

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Interventional radiology:

Varicocele recurrence:

Hydrocele rate

Recurrence

Testicular artery injury

Nerve injury

Testicular atrophy

FOLLOW-UP

Patient Monitoring

Varicocele recurrence:

Typically evident within 6–13 mo

Infertility:

Semen analysis (SA) at 3 mo interval; semen should be monitored for at least 1 yr or until pregnancy has been achieved

Young men with varicocele and normal SA should be followed with tests 3A and FSH every 1–2 yr

VARICOCELE, PEDIATRIC

Hyeyoung Lee, MD, MS
Harry P. Koo, MD, FAAP, FACS

DESCRIPTION
A pediatric varicocele is defined as an abnormal dilatation of the internal spermatic veins in the pampiniform plexus of the spermatic cord in a male generally <18 yr of age. Usually asymptomatic, may cause testicular hypotrophy.

EPIDEMIOLOGY
Incidence
- Reported frequency of varicoceles in adolescent boys is ~16%, developing as a result of testicular enlargement and consequent increased blood flow in puberty
- Actual incidence may be underestimated and detected later during evaluation of infertility in adulthood

Prevalence
- 8–16% of adolescent males but unusual in prepuberty
- 50% left sided
- 1–7% right sided
- 2% bilateral
- No racial, cultural, or geographic predilection
- Unclear how it affects future fertility or hypotrophy

Risk Factors
- Increased height, and relatively low weight and body mass index
- Congenital incompetence or absence of valves of internal spermatic vein
- Acquired incompetence of valves, extrinsic compression increasing intravascular pressure (eg, inguinal hernia repair, retroperitoneal pathologic process)
- May be associated with generalized venous abnormality

Genetics
- Varicocele prevalence as high as 67% has been reported in sons of fathers with varicocele
- Risk of varicocele in 1st-degree relatives is 2–11%

Pathophysiology
- Unique angle of left spermatic vein entering the left renal vein compared to right spermatic vein entering IVC
- Left spermatic vein is 8–10 cm longer than the right
- “Nuckler” phenomenon of left renal vein passing between aorta and superior mesenteric artery
- Erect posture (no varicocele in four-legged animals)
- Different mechanisms are hypothesized to cause testicular insult

- Hyperthermia: Increased testicular arterial blood flow interferes with countercurrent heat exchange
- Increased testicular temperature affects enzymatic reactions
- Decrease proliferation and increased apoptosis of germ cells
- Heat shock protein A2, oxidative stress patterns, calcium-channel, and SDF-1 expression altered

- Testicular hypotrophy: Significantly testicular volume loss in 30–70% of adolescents with a varicocele:
  - Most rapid growth of testses between ages 11 and 16 yr
  - Testicular hypotrophy reversible in 90% of patients after varicocelectomy

- Venous stasis: Possible oxygen deprivation in testes
- Endocrine imbalance: Abnormal response in patients with varicocele to GnRH stimulation
- Unilateral flow if affects future fertility or hypotrophy

Associated Conditions
Secondary causes can include retroperitoneal tumor, renal mass with renal vein extension, renal vein thrombosis, retroperitoneal fibrosis.

GENERAL PREVENTION
None

DIAGNOSIS

History
- Usually asymptomatic, associated pain reported in 2–11%
- Symptomatic dull ache or fullness in scrotum, worsened with activity
- Occasional testicular pain due to venous congestion
- Change in size with position or Valsalva
- Find out routine pediatric physical exam

Physical Exam
- Examine patient, weight, and supine, with and without Valsalva
- Grading criteria:
  - Grade 0: Subclinical, not visible or palpable, only detected by ultrasound (US)
  - Grade 1: Palpable only with Valsalva
  - Grade II: Palpable but not readily visible
  - Grade III: Visible through scrotal skin

- Ultrasound: Determines size and extent of varicocele

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Semen analysis: Can be performed if Tanner stage 5 or >18 yr old
- Response to GnRH stimulation: Not useful for surgical decision making

Imaging
- Scrotal US
- Color Doppler US can detect subclinical varicoceles that are not palpable
- Decrease in volume of 2 cc or 20% size warrants intervention

- Scrotal vein diameter >2 mm in standing position with Valsalva is noted in up to 96% of boys with grade III varicocele
- Lambert formula: 0.71 (length × width × depth

Pathologic Findings
- Varicocele is known to be associated with high levels of luteinizing hormone (LH) and follicle-stimulating hormone (FSH) and low testosterone levels
- Endothelial proliferation and basement membrane thickening in venules and capillaries
- Germ cell maturation arrest and sloughing of germ cells
- Heat shock protein A2, oxidative stress patterns, calcium-channel, and SDF-1 expression altered

DIAGNOSTIC PROCEDURES/SURGERY
Diagnosis confirmed by physical exam or US
DIFFERENTIAL DIAGNOSIS
- Spermatocoele (seminoma)
- Hydrocele:
  - Communicating
  - Scrotal
- Spermatic cord
- Inguinal hernia
- Lipoma of cord
- Peritesticular fibromyxosarcoma

TREATMENT

GENERAL MEASURES
- Management is either observation or surgical intervention
- Nonoperative treatment can be proposed when the patient or guardian fully understands the need for lifelong follow-up and the potential for progressive subfertility
- Surgical indications in the pediatric population:
  - 2 cm or 20% size discrepancy between testicles based on US or orchidometer measurements
  - Symptomatic
  - Bilateral varicoceles
  - Abnormal semen analysis
  - Solitary testis with varicocele

SURGERY/OTHER PROCEDURES
- Surgical techniques based on comfort and experience of surgeon
- Techniques described in more detail in Section 1: "Varicocele, Adult"
- 50–75% of patients demonstrate catch-up growth, not necessarily meaning improved semen quality
- Testicular artery sparing:
  - High ligation of vessels (Palomo)
  - Retroperitoneal or transperitoneal
  - Should be considered in adolescents
- Preferred in adults because of concerns with infertility
- Doppler can help identify
- Possible decreased fertility

MEDICATION
- N/A

SECONDARY TREATMENT
- Radiation Therapy
  - Varicocele, Adult

ADDITIONAL TREATMENT
- Radiation Therapy
  - N/A
- Additional Therapies
  - N/A
- Complementary & Alternative Therapies
  - N/A

ONGOING CARE

PROGNOSIS
- No definitive evidence that adolescents with varicocele will have impaired fertility in future or that surgical correction will improve/prevent infertility

COMPPLICATIONS
- Recurrence or persistence of varicocele:
  - 1–35% depending on technique (3)
- Postoperative hydrocele (1–9%)
- Testicular atrophy
- Failure of catch-up growth
- Possible decreased fertility

FOLLOW-UP
- Patient Monitoring:
  - If asymptomatic and no testicular size discrepancies, not necessarily meaning improved semen quality
  - Contraindicated for recurrent/persistent varicocele
  - Single port laparoscopic approach provides
  - Laparoscopic and open suprainguinal
  - Scrotal, scrotal, and scrotal
  - Communicating varicocele
  - Provides facilitated artery and lymphatic sparing
  - Low-risk of hydrocele
  - Time consuming
  - Radiographic embolization:
    - Simultaneous in children and adolescents, less successful than open or laparoscopic approach
    - Significant radiation exposure
    - Generally reserved for recurrent/persistent varicocele

REFERENCES

ADDITIONAL READING
- Varicocele, Adult

CODES
- ICD9
  - 459.8 Scrotal varices
  - 456.4 Scrotal varices
  - 752.89 Other specified anomalies of genital organs
- ICD10
  - N6.1 Scrotal varices
  - N6.9 Other specified disorders of veins
  - Q64.8 Other specified congenital malformations of urinary system

CLINICAL/SURGICAL PEARLS
- Varicocele is found in 8–16% of adolescents.
- Genetic susceptibility, thin and tall body habitus, and various abnormalities increase the risk of varicocele.
- Surgical treatment is indicated if testicular hypotrophy, bilateral varicocele, abnormal semen analysis or symptoms.
- Laparoscopic and open supravesical varicocelectomy are almost equally effective.
- Microsurgical approach minimizes risk of hydrocele development.
Genetics of CUAVD less understood

- CBAVD without clinical CF

- CFTR: Most common
  - Mutations of cystic fibrosis transmembrane conductance regulator (CFTR)
  - Function: Chloride channel
  - Sites:
    - Lungs, liver, pancreas, intestines
  - Vas deferens/GU tract

- CFTR mutation
  - Point mutations most common in CF
  - Alter chloride transport
  - Thick, viscous secretions
  - Multi-organ disease in CF
  - Obstruction/regeneration of vasa vs. agenesis.
  - Vas deferens is a derivative of mesonephric (Wolffian) duct.
  - Wolfian abnormalities often seen with AVD
  - Seminal vesicle (SV) hypoplasia or absence
  - Causes low-volume ejaculate.
  - See: Associated Conditions

- CF
  - CBAVD is considered the mildest manifestation of CFTR disease spectrum
  - CF is most severe
    - Nearly all CF patients have CBAVD
  - Genitourinary abnormalities
    - Renal agenesis
  - Abnormalities of mesonephric structures
    - Ejaculatory ducts
    - Vasa deferentia
  - Low testicular volume
    - See more commonly when CFTR mutations not detected (48)
  - May indicate primary testicular cause

GENERAL PREVENTION
CFTR screening of both partners can help assess and manage risk of CF and CBAVD for offspring

POTENTIAL SCREENING TESTING
- CFTR genetic mutation screen
  - Part of evaluation for low-volume azoospermia
  - Evaluates for mild vs. severe mutations
  - Can prove, but not exclude, a congenital form of CF
  - Risk is difficult to predict with some rare CFTR mutations
  - Negative CFTR screen reduces, but does not eliminate, risk of being a carrier
  - Thus, suggest screening in female partner
  - CFTR screening for partner
  - Helps guide genetic counseling regarding CF risk for offspring

- Diagnostic tests & interpretation
  - Lab
    - Potential semen analysis findings:
      - Low volume (<1.5 cc)
      - Azoospermia if bilateral obstruction
      - Acidic pH (increased SV fluid)
      - Seminal fructose might be negative
      - Presence of sperm rules out bilateral obstruction
    - Postejaculatory utrality
      - Evaluates for retrograde ejaculation
    - For all men with vasal agenesis
      - CFTR genetic mutation screen
    - Seminal vesicle (SV) hypoplasia or absence
    - Evaluates for retrograde ejaculation
    - Seminal vesicle (SV) hypoplasia or absence
    - Causes low-volume ejaculate.
- Pathophysiology
  - CFTR
    - Cystic fibrosis transmembrane conductance regulator
    - Function: Chloride channel
    - Sites:
      - Lungs, liver, pancreas, intestines
    - Vas deferens/GU tract
  - CFTR mutation
    - Point mutations most common in CF
    - Alter chloride transport
    - Thick, viscous secretions
    - Multi-organ disease in CF
    - Obstruction/regeneration of vasa vs. agenesis.
    - Vas deferens is a derivative of mesonephric (Wolffian) duct.
    - Wolfian abnormalities often seen with AVD
    - Seminal vesicle (SV) hypoplasia or absence
    - Causes low-volume ejaculate.
    - See: Associated Conditions
- CBAVD
  - CBAVD is considered the mildest manifestation of CFTR disease spectrum
  - CF is most severe
    - Nearly all CF patients have CBAVD
  - Genitourinary abnormalities
    - Renal agenesis
  - Abnormalities of mesonephric structures
    - Ejaculatory ducts
    - Vasa deferentia
  - Low testicular volume
    - See more commonly when CFTR mutations not detected (48)
    - May indicate primary testicular cause

- Diagnostic tests & interpretation
  - Lab
    - Potential semen analysis findings:
      - Low volume (<1.5 cc)
      - Azoospermia if bilateral obstruction
      - Acidic pH (increased SV fluid)
      - Seminal fructose might be negative
      - Presence of sperm rules out bilateral obstruction
    - Postejaculatory utrality
      - Evaluates for retrograde ejaculation
    - For all men with vasal agenesis
      - CFTR genetic mutation screen
    - Seminal vesicle (SV) hypoplasia or absence
    - Evaluates for retrograde ejaculation
    - Seminal vesicle (SV) hypoplasia or absence
    - Causes low-volume ejaculate.
- Pathophysiology
  - CFTR
    - Cystic fibrosis transmembrane conductance regulator
    - Function: Chloride channel
    - Sites:
      - Lungs, liver, pancreas, intestines
    - Vas deferens/GU tract
  - CFTR mutation
    - Point mutations most common in CF
    - Alter chloride transport
    - Thick, viscous secretions
    - Multi-organ disease in CF
    - Obstruction/regeneration of vasa vs. agenesis.
    - Vas deferens is a derivative of mesonephric (Wolffian) duct.
    - Wolfian abnormalities often seen with AVD
    - Seminal vesicle (SV) hypoplasia or absence
    - Causes low-volume ejaculate.
    - See: Associated Conditions
  - CBAVD
    - CBAVD is considered the mildest manifestation of CFTR disease spectrum
    - CF is most severe
      - Nearly all CF patients have CBAVD
    - Genitourinary abnormalities
      - Renal agenesis
    - Abnormalities of mesonephric structures
      - Ejaculatory ducts
      - Vasa deferentia
    - Low testicular volume
      - See more commonly when CFTR mutations not detected (48)
      - May indicate primary testicular cause
    - General Prevention
      - CFTR screening of both partners can help assess and manage risk of CF and CBAVD for offspring
    - Physical Exam
      - Findings in AVD
        - Absent vas deferens (bilateral/unilateral)
        - Absent or hypoplastic body/tail of epididymis
        - Present caput epididymis, often dilated
      - Considerations:
        - Evaluate for skip lesions
        - Check for other causes of infertility
        - Varicocele
        - Azoospermic tests
        - Normal in CBAVD:
          - Tests size (<3.5 cm length, 2–3 cm diameter)
        - Digital rectal exam:
          - Prostate usually normal
          - Tis usually nonpalpable/hypoplastic, may be cyclic
GENERAL MEASURES

- Transrectal ultrasound (TRUS)
  - Allows for evaluation of low-volume azoospermia
  - Not necessary with CBAVD
- Evaluate for ejaculatory duct obstruction
- Normal findings:
  - SV diameter: 0.3–0.5 cm
  - SV length: 1.4–4.6 cm
- Ejaculatory duct diameter: <0.1 cm
- Abnormal findings:
  - SV diameter: >1.5 cm
  - SV length: >4.6 cm
- Vaso-epididymal obstruction
- Varicocele

Differential Diagnosis

- Spermatogenic failure causing azoospermia
  - Congenital/gene causes:
    - 17q12-q21 microdeletions
    - Sex chromosome abnormalities (D4Y male)
    - Undescended testes
  - Inflammatory causes:
    - Gonadotropin exposure
    - Radiation
    - Experimental
- Obstruction causing azoospermia
  - Inflammatory or infectious causes:
    - Tuberculosis
    - Sexually transmitted infections
    - Environmental
    - Radiation
  - Congenital causes:
    - Undescended testes
    - Sex chromosome abnormalities (XY male)
    - Y chromosome microdeletions
  - Drugs:
    - Gonadotropin exposure
    - Radiation

Pathologic Findings

- CF or CBAVD in offspring

Diagnostic Procedures/Surgery

- Vasography
  - Fluoroscopic injection of contrast material
  - Evaluates for sperm retention
- Vasography (see below)
- Transrectal ultrasound (TRUS)
  - Assesses patency of vas/vasa
- Fluoroscopic injection of contrast material
  - Evaluates for ejaculatory duct obstruction
  - Not necessary in CBAVD

Second Line

- Medications used only to treat other conditions
- Fertilization and pregnancy rates with ART in obstructive azoospermia are most closely tied to obstructive azoospermia
- Sperm retrieval techniques (ART)
  - IVF/ICSI
  - Intrauterine insemination
  - See Surgery, below

Sperm retrieval techniques

- Donor semen
- Intravaginal insemination
- ICSI
- Consider referral for genetic counseling regarding CF risk for offspring

SURGERY/OTHER PROCEDURES

- Sperm retrieval for ART
  - Testicular sperm extraction (TESE)
  - Microsurgical epididymal sperm aspiration (MESA)
  - Sperm can be used for IVF or ICSI

ADDITIONAL TREATMENT

- Radiation Therapy
- Additional Therapies
- Complementary & Alternative Therapies

ONGOING CARE

- Ongoing care includes management of infertility
- Continuous monitoring of semen analysis
- Medications used only to treat other conditions

COMPLICATIONS

- Of limited utility in CBAVD since reconstruction of ejaculatory ducts, due to risk of damage/obstruction at vasa entry point
- Of limited utility in CBAVD since reconstruction usually not an option

TREATMENT

- Infertility treatment requires assisted reproductive techniques (ART)
- Sperm retrieval techniques
  - See Surgery, below
- Donor semen
  - Intravaginal insemination
  - ICSI
- Consider referral for genetic counseling regarding CF risk for offspring

PROGNOSIS

- Fertilization and pregnancy rates with ART in obstructive azoospermia
- Penetrance of cystic fibrosis gene mutations.
- Incomplete penetrance of cystic fibrosis gene mutations.
- Low-volume ejaculate in CBAVD and CUAVD is usually not an option

MEDICATION

- First Line
  - Medications used only to treat other conditions
- Fertilization and pregnancy rates with ART in obstructive azoospermia
- Intrauterine insemination
- IVF/ICSI

SECOND LINE

- IVF/ICSI

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Radiation therapy
- Additional therapies

Coding

ICD9
- 752.89 Other specified anomalies of genital organs
- 752.89 Other specified anomalies of genital organs
- 752.89 Other specified anomalies of genital organs
- 752.89 Other specified anomalies of genital organs

VASECTOMY AND POSTVASECTOMY PAIN SYNDROME

Christopher L. Starks, MD
Edmund S. Sabanegh, Jr, MD

BASICS

DESCRIPTION

- Vasectomy is a surgical procedure that creates a disruption of the vas deferens leading to permanent male sterilization
  - Vasectomy is the safest, least expensive, and most reliable form of sterilization (1,2)
- Postvasectomy pain syndrome: Poorly understood and largely unpredictable chronic testicular pain
  - 3 mo duration after vasectomy
  - Variable constellation of symptoms including but not limited to orchialgia, pain with daily activities, and pain with intercourse/jaculation

EPIDEMIOLOGY

Incidence

- Vasectomy: Number of vasectomies performed each year is >150,000–500,000
- Postvasectomy pain syndrome: 15–35% of men may experience persistent mild to troublesome testicular discomfort following vasectomy with 4% experiencing significant long-term testicular pain
- Long-term pain requiring some kind of intervention or surgical therapy occurs in up to 1 in 1,000 vasectomized men

Prevalence

- ~5% of couples of reproductive ages rely on vasectomy for contraception

RISK FACTORS

N/A

GENETICS

N/A

PATHOPHYSIOLOGY

- Vasectomy: Vasectomy involves disrupting the vas deferens via several methods: electrocautery, clips, and/or fascial interposition
  - Vasectomy disrupts the blood-tissue barrier
  - Antisperm antibodies in 60–80% of men
  - Does not appear to result in cell-mediated immunity

- Postvasectomy pain syndrome: Proposed mechanisms:
  - Increased pressure on the testicle and epididymis
  - Nerve entrapment
  - High pressure may cause blowouts of sperm resulting in tender sperm granulomas and epididymal regions

ASSOCIATED CONDITIONS

N/A

GENERAL PREVENTION

No preoperative factors have been identified in the postvasectomy pain syndrome

DIAGNOSIS

HISTORY

- Vasectomy: A careful history ensuring that the patient understands that this is a permanent method of sterilization should occur
  - A directed history including previous scrotal and inguinal surgery
- Postvasectomy pain syndrome: Mean time to onset of pain reported as 2 yr
  - Symptoms associated with postvasectomy pain syndrome include:
    - Persistent pain in the groin, testicle, or epididymis
    - Pain with an erection and/or engaging in sexual activity
    - Decreased libido and/or erections

PHYSICAL EXAM

- Pre-vasectomy: Analysis of testicular histology after vasectomy
  - Routine histologic exam of excised vas segment is not required
- Post-vasectomy pain syndrome: Physical exam commonly reveals:
  - Fullness/tenderness at the proximal vas, epididymis, or at a granuloma site
  - Evidence of sperm granuloma
  - Epididymal tenderness or other masses
  - Evince for evidence of groin hernia

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Nonsteroidal anti-inflammatory medication
  - Usually not necessary
- Ultrasound imaging can confirm epididymal engorgement, thickening, or nodularity

TREATMENT

GENERAL MEASURES

First Line
- Nonsteroidal anti-inflammatory medication
  - Usually not necessary
- Ultrasound imaging can confirm epididymal engorgement, thickening, or nodularity

ALERT

Patients must be fully informed that an alternative form of birth control must be used immediately after vasectomy and until a semen analysis is clear.

DIFFERENTIAL DIAGNOSIS

- Vasectomy: A minimally invasive or “no-scalpel vasectomy” technique should be used
  - Methods of performing vasectomy are based upon surgeon preference. These include:
    - Excision of a portion of the vas
    - Clips vs. suture ligation of vas ends
    - Cautery of mucosa
    - Interposition of the vas ends between fascia (may reduce recanalization)
- Postvasectomy pain syndrome:
  - Conservative therapies are the mainstay: Scrotal support, activity limitation, sitz baths, ice-packs

SECOND LINE
- Tricyclic antidepressants and neuroleptic medication (eg, gabapentin) can be considered

PHYSICAL EXAM

- Pre-vasectomy pain syndrome: Analysis of testicular histology after vasectomy
  - Routine histologic exam of excised vas segment is not required
- Post-vasectomy pain syndrome: Analysis of testicular histology after vasectomy
  - Demonstrates disturbance of the seminiferous tubules, interstitial fibrosis, and reductions in the seminiferous cell population

MEDICATION

First Line
- Nonsteroidal anti-inflammatory medication
  - Usually not necessary
- Ultrasound imaging can confirm epididymal engorgement, thickening, or nodularity

SECOND LINE
- Tricyclic antidepressants and neuroleptic medication (eg, gabapentin) can be considered
VASECTOMY AND POSTVASECTOMY PAIN SYNDROME

SURGERY/OTHER PROCEDURES
- Postvasectomy pain syndrome
- With the failure of long-term conservative management, more invasive treatments: Sperm granuloma excision, denervation of the cord, open-ended vasectomy, epididymectomy, and orchiectomy may be considered
- With pain localized to a sperm granuloma on physical exam, granuloma excision with occlusion of vas with intraluminal cautery usually relieves the pain and reduces the risk of recurrence
- In 1 study up to 50% were pain-free following epididymectomy
- Epididymectomy renders the vasectomy completely irreversible and may jeopardize the blood supply to the testes, which can result in ischemic atrophy
- Vasectomy reversal: There are no controlled trials, but reversal may offer best chances of significant improvement (50% pain free in 1 series). The drawback is that fertility is restored (3)

ADDITIONAL TREATMENT
Radiation Therapy

Additional Therapies
- Postvasectomy pain syndrome
- Men with intractable symptoms might benefit from a multidisciplinary team approach involving a urologist and pain-clinic specialist, including a psychologist
- Many men with chronic orchalgia also had signs of major depression or chemical dependencies (4)
- Spermatic cord blocks
- Local neurolysis/cordotomy
- Transrectal injections into the region of pelvic plexus (5 mL bupivacaine and methyl prednisolone) have been used to manage cases of ischemic atrophy
- Denervation of the cord, clips, suture ligation, cautery, and fascial interposition
- There are rare complications from vasectomy
- Other complications from vasectomy include hematoma and postvasectomy pain syndrome
- Vasectomy should be considered a failure if nonmotile sperm are present at 6 mo after vasectomy

COMMENTS
- Vasectomy should be considered if they do not desire permanent sterilization

ONGOING CARE

PROGNOSIS
- Postvasectomy pain syndrome does not work immediately
- They should use contraceptives and consider themselves fertile until a postvasectomy semen analysis (PVSA) is negative
- Even once vas occlusion is confirmed, the risk of preventing pregnancy is not 100% reliable. Risk of pregnancy is 1 in 2,000 for men who have PVSA showing azospermia or rare nonmotile sperm
- Repeat vasectomy is needed in ~1%
- Despite counseling, up to 5% of men will change their mind postvasectomy and request a vasectomy reversal

COMPLICATIONS
- Bleeding/hematoma: ~1–2%
- Infection: <1%
- Symptomatic sperm granuloma: <1%
- Postvasectomy pain syndrome: 15–33%

FOLLOW-UP

Patient Monitoring
- PVSA should be a first-unsurgated semen sample and should be examined within 1–2 hr of ejaculation
- PVSA can be made by the patient between 8–16 wk after vasectomy
- Acceptable PVSA show azospermia or only rare nonmotile sperm
- Vasectomy should be considered a failure if motile sperms are present at 6 mo

Patient Resources

- Vas Deferens, Obstruction
- Vasectomy Reversal

CODES
ICD9
- 631.18 Other acute postoperative pain
- 608.89 Other specified disorders of male genital organs
- Z16.52 Vasectomy status

ICD10
- C68.18 Other acute postprocedural pain
- N00.8 Other specified disorders of male genital organs
- Z06.2 Vasectomy status

CLINICAL/SURGICAL PEARLS
- A minimally invasive approach to accessing the vas (ie, no scalpel vasectomy) should be used
- There are a variety of methods and techniques that can be used to disrupt the vas bilaterally including excision, clips, subcuticular suture, cautery, and facial incision
- There are rare complications from vasectomy including hematoma and postvasectomy pain syndrome
VESICOURETERAL REFLUX, ADULT
Sanjay S. Kasturi, MD

DESCRIPTION

- Vesicoureteral reflux (VUR) is defined as retrograde passage of urine from the bladder into the ureter and/or renal pelvis and calyces.
- VUR in the presence of bacteria is a risk factor for pyelonephritis and may lead to upper tract pathologic changes, which may be unilateral or bilateral, primary or secondary.
- A more common problem in children, it can be associated with significant morbidity in adults and may be an uncommonly unrecognized cause of hypertension (HTN) in this population.

EPIDEMIOLOGY

Incidence
- 5% of adults have VUR at the time of evaluation.
- Female
- Family history of VUR

Secondary VUR
- Conditions that predispose to secondary VUR (eg, neurologic bladder)
  - Genitourinary TB can cause the ureteral orifices to become fixed and relatively patulous
  - Bacterial cystitis can often cause transient ureteral reflux due to inflammation
  - Patients who have undergone urinary diversion (ileo/colonic conduit) may develop ureteric reflux
  - Congenital deficiency of the intravesical tunnel is the most common etiology

PHYSIOPATHOLOGY

Primary VUR (1)
- Failure of development or breakdown of the distal ureteral antireflux mechanism
- Normally, the distal 4–5 cm of the ureter courses through the muscular wall of the bladder before reaching the bladder trigone
- This tunnel prevents reflux of urine
- Congenital deficiency of the intravesical tunnel is the most common etiology

Secondary VUR
- Disorders that cause elevated intravesical pressure: BPH, spinal cord injury, MS, and other neurologic diseases
- Patients who have undergone urinary diversion (ileo/colonic conduit) or Bladder replacement (prosthetic neobladder, catheterizable diversions) commonly have VUR
- Bacterial cystitis can often cause transient ureteral reflux due to inflammation

Diagnosis

History
- History of VUR in childhood
- Family history of VUR
- Recurrent UTIs
- Simple cystitis leading to fever and flank pain suggestive of pyelonephritis
- Lower urinary tract voiding symptoms, suggesting outlet obstruction or neuropathic bladder

Physical Exam
- CVK tenderness with pyelonephritis
- Digital rectal exam for BPH
- Palpable bladder
- Neurologic impairment
- HTN (if renal compromise)

Diagnostic Tests & Interpretation

Lab
- Blood testing is not necessary, except for severe cases in which renal function should be evaluated.
- Proteinuria (if renal compromise)

Imaging
- US can show hydronephrosis dependent on severity of VUR
- VCUG: Definitive test for identifying and grading the severity of reflux. It may also point toward the cause of VUR
- A nuclear medicine cystogram (indirect VCUG): – Can be performed with MAG3
  - Provides less anatomic information than the VCUG but does not require catheterization

Pathologic Findings
- Renal lesions (scarring) can be associated with higher grades of reflux
- Chronic scarring may, over time, cause HTN

DIFFERENTIAL DIAGNOSIS

- Other causes of flank (renal) pain and infection (eg, renal colic, urosepsis/junction obstruction) (see Section I: “Flank Pain”)
- Other causes of hydroureteronephrosis or ureteral obstruction (see Section I: “Hydronephrosis/Hydroureteronephrosis (Dilated Ureter/Renal Pelvis), Adult”)

Medication

First Line
- Patients with recurrent UTI may benefit from prophylactic antibiotics
- Other causes of VUR (see Section I: “Hydronephrosis/Hydroureteronephrosis, Adult”)
- Early treatment of cystitis can prevent progression to pyelonephritis.
VESICOURETERAL REFLUX, ADULT

Second Line

Secondary VUR may benefit from medical treatment of underlying cause:

– Anticholinergic preparations in detrusor overactivity
– α-Blockade or 5α-reductase inhibition in bladder outlet obstruction

SURGERY/OTHER PROCEDURES

Primary VUR rarely requires surgical intervention in adults; however, where indicated procedures include:

– Endoscopic treatment: Injection of bulking agents below the ureteral orifice:
  ◦ Initial results are good; however, long-term follow-up is scant

Several agents have been used for endoscopic correction of VUR:

◦ Polytetrafluoroethylene (Teflon)
◦ Cross-linked bovine collagen, dextranomer/hyaluronic copolymer (Deflux)

Since the FDA approval of Deflux in 2001, this has been the most commonly used injectable agent for VUR

– Ureteric reimplantation can be undertaken transvesically, extravesically, or by a combination of both:
  ◦ Some common techniques include: Cohen cross-trigonal, Politano–Leadbetter, Lich–Gregoir (extravesical) reimplantations

ADDITIONAL TREATMENT

Complementary & Alternative Therapies
Some data suggest cranberry juice and live-culture yogurt can be effective in preventing UTI

ON GOING CARE

PROGNOSIS
Depends on underlying etiology and severity of VUR

COMPICATIONS (3,4)

– Chronic pyelonephritis
– Reflux nephropathy
– Renal impairment in primary VUR unless pre-existing from childhood, but can be encountered in secondary VUR
– UTI
– Urolithiasis

FOLLOW-UP

Patient Monitoring

Medical follow-up is unnecessary in patients without HTN or proteinuria, unless the patient develops recurring infections, at which point repeat workup is needed

– Patients with intrinsic renal disease due to prior reflux (in childhood) require follow-up of BP, creatinine, and urine protein

Patient Resources

– Urinary Tract Infection (UTI), Complicated, Adult
– Vesicoureteral Reflux, Adult Image

CODES

ICD9

593.70 Vesicoureteral reflux unspecified or without reflux nephropathy
593.721 Vesicoureteral reflux with reflux nephropathy, unilateral
593.729 Vesicoureteral reflux with reflux nephropathy NOS

ICD10

N13.30 Vesicoureteral reflux, unspecified
N13.321 Vesicoureteral reflux with reflux nephropathy without hydronephrosis
N13.322 Vesicoureteral reflux with reflux nephropathy with hydronephrosis

CLINICAL/SURGICAL PEARLS

Women with VUR tend to present with infections, while men tend to present with HTN and proteinuria.
VESICOURETERAL REFLEX, PEDIATRIC

Kathleen Kieran, MD, FAAP, FACS
Christopher S. Cooper, MD, FAAP, FACS

ASSOCIATED CONDITIONS

- Primary VUR: Hydronephrosis, UTI, bladder/bowel dysfunction
  - V: Severe ureteral tortuosity
  - IV: Renal pelvis and calyces with ureteral tortuosity
  - II: Renal pelvis and calyces without dilatation
  - I: Ureter only
- Secondary VUR: Optimizing lower urinary tract function to prevent elevated pressure and decreased bladder compliance

GENETICS

- Likely autosomal dominant with incomplete penetrance
- Seen in 27–51% of siblings of children with VUR, up to 100% in identical twins
- Seen in 50–64% of children of parents with VUR

PATHOPHYSIOLOGY

- The normal ureter enters the bladder at an obtuse angle through the bladder wall; with bladder filling on contraction, the ureter is compressed and retrograde flow of urine (reflux) is prevented.
- Primary VUR is associated with a functionally shortened submucosal tunnel
- Secondary VUR occurs in the setting of abnormal lower urinary tract function with resulting increase in bladder pressures
- VUR is graded on a scale of I–V
  - I: Linear only
  - II: Renal pelvis and calyces without dilatation
  - III: Renal pelvis and calyces with calyceal blunting
  - IV: Renal pelvis and calyces with ureteral tortuosity
  - V: Severe ureteral tortuosity

DIAGNOSTIC TESTS & INTERPRETATION

- Complete physical exam for baseline functional information
  - Neurologic exam for spina bifida
  - Abdominal and pelvic exam:
    - Palpable kidneys secondary to hydronephrosis
    - Palpable bladder secondary to incomplete emptying
  - CVaT tenderness
  - Suprapubic tenderness
  - Circumcision status in males
- Blood pressure should be compared with age-adjusted normative values
- Identify or exclude causes of secondary VUR, eg, neurogenic bladder

DIAGNOSTIC PROCEDURES/SURGERY

- Voided specimen urine samples are more accurate for diagnosis of infection but are more costly and invasive; collect in patients with high index of suspicion based on voided sample or in patients with history of VUR
- Blood cultures sent only when urine analysis or clinical presentation is suspicious for infection
- Serum creatinine and electrolytes are not routinely checked unless significant sonographic anomalies in renal units, history of multiple febrile UTIs, or significant renal scarring on radionuclide imaging; evaluate at initial diagnosis and again only when substantial change in clinical condition

DIAGNOSTIC TESTS & INTERPRETATION

- Voided specimen urine for assessment of proteinuria, evidence of infection
- Catherized urine samples are more accurate for diagnosis of infection but are more costly and invasive; collect in patients with high index of suspicion based on voided sample or in patients with history of VUR
- Cultures sent only when urine analysis or clinical presentation is suspicious for infection

DIAGNOSTIC PROCEDURES/SURGERY

- Diagnosis of renal scarring may suggest presence of VUR but are not sensitive or specific enough for definitive diagnosis
- Renal ultrasound utilized to help define upper tract anatomy, eg, hydronephrosis or duplicated systems, assess quality of renal parenchyma, ensure adequate renal growth
- Renal scintigraphy (DMSA scan) is the gold standard for detection of renal scarring
  - Differential renal function
  - Diagnosis of acute pyelonephritis/scarring

DIFFERENTIAL DIAGNOSIS

- Should be based on the abnormal symptom or clinical finding that prompted the evaluation
  - UTI: Dysuria, lower tract infection vs. pyelonephritis
  - Hydronephrosis: Physiologic hydronephrosis, ureteropelvic junction obstruction, ureteropelvic junction obstruction, congenital megareter
  - Always consider secondary causes when evaluating for VUR

GENERAL MEASURES

- Counsel parents on pathophysiology and natural history of VUR; Causes, contraindications, potential sequelae, likelihood of resolution, risks and benefits of alternative treatment plans
- Spontaneous resolution of primary reflux is common and depends on initial grade of reflux, gender, age, voiding dysfunction, presence of renal scarring, and timing of VUR on VCUG
- Goal of intervention is to prevent renal scarring, recurrent febrile UTI, and long-term complications such as hypertension and renal insufficiency

IMAGING

- Voiding cystourethrogram (VCUG) or radionuclide cystogram
ADDITIONAL TREATMENT

Surgery/Other Procedures

Second Line

Management of elimination habits:
- Use of anticholinergic medications when reflux is refractory to behavioral modification

Surgey/other procedures
- Endoscopic intervention:
  - Can be performed via intra- or extravesical
  - Higher success rate (95–99%)
  - Only 1 currently in use in US: Deflux, Salix
- Surgical intervention recommended for persistent VUR, worsening renal function, recurrent UTIs

Patient Monitoring
- Patients with VUR:
  - Annual complete physical exam with blood pressure check and urinalysis (proteinuria, infection)
  - Imaging: No consensus on interval, but general agreement of renal ultrasound and cystography every 1–2 yr

FOLLOW-UP

Patient Monitoring
- Patients with VUR:
  - Annual complete physical exam with blood pressure check and urinalysis (proteinuria, infection)
  - Imaging: No consensus on interval, but general agreement of renal ultrasound and cystography every 1–2 yr

ICD9
- 582.73 Vesicoureteral reflux unspecified or without reflux nephropathy
- 753.5 Estrophy of urinary bladder
- 756.71 Prune belly syndrome

ICD10
- N13.70 Vesicoureteral reflux, unspecified
- O04.15 Exstrophy of urinary bladder, unspecified
- Q94.9 Prune belly syndrome
ASSOCIATED CONDITIONS
- Genetics
  - Prevalence in USA: About 7,000 people
- Incidence
  - Rare: 1 in 35,000 live births
- Prevalence
  - Prevalence in USA: About 7,000 people
- Risk Factors
  - Inheritance of a mutated VHL allele
  - No gender or racial predilection
- Genetics
  - Autosomal dominant inheritance pattern
  - VHL is a tumor suppression gene on chromosome 3p25–26 (3)
  - Affected individuals inherit 1 copy of a mutated VHL from the affected parent
  - The loss or mutation of the 2nd (initially normal) allele in the cell leads to tumor formation (mechanism known as a 2-hit model)
  - Present technology identifies the mutated gene in 100%
- Pathophysiology
  - Mutated VHL leads to aberrant VHL protein (pVHL)
  - Abnormal pVHL is unable to target hypoxia inducible factor (HIF) for degradation
  - Accumulation of HIF protein upregulates downstream genes such as VEGF, GLUT-1, PGF, TGF-β, HIF, and many others, leading to tumor formation
- Associated Conditions
  - Multifocal and bilateral ccRCC in 50%
  - Renal cysts seen in up to 70%
  - Papillary cystadenomas in about 20%
  - CNS hemangioblastomas in 75%
  - Retinal angiomas in 50–50%
  - Pancreatic cysts seen in up to 60%
  - ELST in 5–10%
  - Papillary cystadenomas of the epididymis or broad ligament in <1%
  - VHL-associated lung cysts/hematomas in <1%
  - VHL-associated ovarian tumors in <1%

GENERAL PREVENTION
- Close surveillance of affected individuals and timely intervention
- Genetic screening of family to initiate early surveillance

DIAGNOSIS

HISTORY
- Early history of RCC or pheochromocytoma, CNS or pancreatic surgery, hearing or vision problems is often elicited
- Patients may present with ≥1 symptoms related to the organ involved
- Renal tumors and cysts:
  - Usually detected incidentally or during screening by imaging in VHL patients
  - May present with hematuria, flank pain, abdominal fullness, weight loss, cachexia in advanced disease
- Pheochromocytoma:
  - Headaches, palpitations, episodic sweating, anxiety attacks, personality changes
  - Severe hypertension (HTN) leading to hemorrhagic stroke
  - May present with weight loss, cachexia, bone pain, or cough in setting of metastatic disease
- May be asymptomatic
- CNS hemangioblastomas:
  - Often asymptomatic
  - Headaches, vertigo, ataxia, vomiting, wide-based gait, sensory loss, seizures
  - Size and location of the lesion(s) often determine symptoms
- Retinal angiomas:
  - Blurred or decreased vision, eye pain
  - If undetected, may present with blindness
- Pancreatic NET and cysts:
  - Most are asymptomatic
  - Diabetes, steatorrhea, and diabetes may occur if panceas is replaced by cysts
  - Early satiety if pancreatic cysts are large and compressing the stomach
  - Bone pain and paraneoplastic jaundice in rare cases of extrinsic compression of the biliary system or metastatic disease
- CNS hemangioblastomas:
  - Nystagmus, papilledema, loss of proprioception, and sensory deficits
- Retinal angiomas:
  - Decreased visual acuity, characteristic retinal hemangioblastomas, and retinal detachment
- Pancreatic NET:
  - Undetected on exam unless large in size, metastatic, or causing obstruction
- ELST:
  - Decrease or loss of hearing
  - Papillary cystadenomas of the epididymis
  - Parasitol tends to develop:
    - Extra-adrenal pheochromocytomas
- Baseline imaging:
  - Elevated plasma and urine catecholamines are seen in patients with pheochromocytoma
  - Increased plasma and urine metanephrines are most commonly elevated in VHL patients
  - Other catecholamines may also be elevated
  - Similar to sporadic ccRCC:
    - Hypercalcemia, erythrocytosis, anemia, or elevated liver function tests (LFTs) may be seen as paraneoplastic lab abnormalities
  - Elevated erythropoietin levels or erythrocytosis may be seen with CNS involvement

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Elevated plasma and urine catecholamines are seen in patients with pheochromocytoma
- Increased plasma and urine metanephrines are most commonly elevated in VHL patients
- Other catecholamines may also be elevated
- Similar to sporadic ccRCC:
  - Hypercalcemia, erythrocytosis, anemia, or elevated liver function tests (LFTs) may be seen as paraneoplastic lab abnormalities
- Elevated erythropoietin levels or erythrocytosis may be seen with CNS involvement

Imaging
- Bone and spine magnetic resonance imaging (MRI) for detection of CNS hemangioblastomas and ELSTs
- Abdominal imaging: Ultrasound (US) in children, and computed tomography (CT) or MRI in adults; for detection of renal or pancreatic masses, as well as adenial and extra-adrenal pheochromocytomas
- Magnetic resonance imaging (MRI) scan is helpful in localizing active pheochromocytoma
- Chest CT or MRI may be helpful for extra-abdominal pheochromocytomas

Differential Diagnosis
- Genetic testing
  - Occasionally, the glucagon stimulation test or clonidine suppression for pheochromocytoma

Pathologic Findings
- ccRCC
  - Usually multifocal and bilateral
  - May be several hundreds of gross and microscopic lesions in a single kidney
  - Most commonly fumarase nuclear grade II
  - Cysts commonly lined by clear cells
- Papillary cystadenomas of the epididymis
  - Vascular and vascular
  - Frequently multifocal and bilateral
  - Microscopic foci of cells in round clusters
- CNS hemangioblastomas
  - Solitary or multiple lesions in cerebellum, spinal cord, brainstem, or cerebrum
- Benign vascular lesions
Papillary cystadenomas of the epididymis or the pancreas: Benign (1)

Other familial types of hereditary renal carcinoma: Non-VHL familial bilateral multifocal RCC

Multiple endocrine neoplasia type 2 (MEN-2)

Metastatic RCC or other primary

Papillary cystadenomas of the epididymis or the pancreatic NET: Benign (2)

Vigilant surveillance of kidneys, adrenals, pancreas, and renal masses

Succinate dehydrogenase B (SDHB) deficiency: May metastasize to liver or bones unless resected

SDHB deficiency: Increase metastatic potential

No metastasis with solid RCC lesions

Growth rate similar to sporadic counterpart of about 3 mm on average per year

Pancreatic NET: May metastasize to liver or bones unless resected

Pancreatic NET also increase metastatic potential

The type of surgical resection and procedure is determined by tumor size and location

No VHL-specific medical treatment

Surgeries, hearing or vision problems.

Retention angiomas: Laser ablation or cryotherapy

Brain and spinal cord

With CT or MRI for kidneys, adrenal, pancreas; and MRI for brain or spinal cord

MRI for brain or spinal cord

With CT or MRI for kidneys, adrenal, pancreas; and MRI for brain or spinal cord

Surgeries, hearing or vision problems.

Genetic counseling, ophthalmology, neurosurgery, and otolaryngology support as needed

Blindness

Severe neurologic deficit or paralysis

Hypertensive crisis resulting in hemorrhagic stroke

With a fibrous stroma

Well circumscribed but unencapsulated

Microscopic: Nests of polygonal cells with a fibrous stroma

Microscopic: Low-grade papillary

– Bilateral nephrectomies and renal transplantation

– Treatment of pheochromocytoma is preferred

– Higher risk of miscarriage with active pheochromocytoma

– Yearly abdominal US from age 10 yr

– Yearly urinary catecholamines from age 2 yr

– Yearly ophthalmologic exam from birth

Pancreatic NET: Pheochromocytoma

Pheochromocytoma, or pancreatic NET

Ongoing Care

PROGNOSIS

Much depends on the stage of the renal lesions at presentation

Growth rate similar to sporadic counterpart of about 3 mm on average per year

No metastasis with solid RCC lesions <3 cm (2)

Metastatic potential of RCC lesions increases with increase in the size of the lesion, with up to 50% metastasis in those with tumors >6 cm

Pancreatic NET also increase metastatic potential with increase in size

COMPlications

Hyperviscous crisis resulting in hemoragic stroke

Severe neurologic deficit or paralysis

Blindness

Metastatic disease from either RCC, pheochromocytoma, or pancreatic NET

FOLLOW-UP

Patient Monitoring

Radiographic surveillance is performed every 1–2 yr

With CT or MRI for kidneys, adrenal, pancreatic, and MRI for brain or spinal cord

More frequent for faster-growing lesions

Ophthalmology exams yearly

Otology exams every 5 yr

Pediatric considerations

– Yearly ophthalmologic exams from birth

– Yearly urinary catecholamines from age 2 yr

– Yearly abdominal US from age 10 yr

Pregnancy considerations

– Higher risk of miscarriage with active pheochromocytoma

– Treatment of pheochromocytoma is preferred before pregnancy or early in the pregnancy

WILMS TUMOR (NEPHROBLASTOMA)
Jonathan S. Karpelovsky, MD, PhD
Grahame H.H. Smith, MBBS

ASSOCIATED CONDITIONS
- Congenital anomalies in <15% of Wilms tumors
  - GU anomalies: Renal anomalies, cryptorchidism, hypopigmentation, ureteral duplication, ambiguous genitalia (4%)
  - Hemihyperplasia (3%)
  - Aniridia (1%)
  - Denys–Drash syndrome (male pseudohemaphroditism, renal mesangial sclerosis, renal failure)
  - WAGR syndrome
  - Beckwith–Wiedemann syndrome (macroGLOSSIA, organomegaly, hemihyperplasia)
  - Other: Perlman syndrome, Sotos syndrome, Simpson–Golabi–Behmel syndrome

GENERAL PREVENTION
- N/A

DIAGNOSIS

HISTORY
- Abdominal mass
- Fever, anorexia, weight loss
- Hematuria
- Physical exam
- N/A

PHYSICAL EXAM
- N/A

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- CBC: Anemia, polycythemia
- Liver function tests
- U/B creatinine
- Serum calcium
- Urine analysis: 25% with microhematuria
- Coagulation studies to assess for an acquired von Willebrand disease

Imaging
- Abdominal US: Initial study and if there is any concern about intravascular extension
- CT of abdomen and chest: To detect smaller lesions in either renal unit not detected by US; these imaging to evaluate for pulmonary metastasis
- Bone scan: If history of bone pain or elevated alkaline phosphatase or serum Ca

Diagnostic Procedures/Surgery
- N/A

Pathologic Findings
- Gross: Solid or grapelike, feathery tumor with a pseudocapsule
- Microscopic: (3 features): Stromal (immature spindle cells) and can have muscle cartilage or fat; epithelial (recapitulates kidney with glomerular and tubular), and blastemal (undifferentiated cells)
- Venous invasion in up to 20%; usually single tumor; 7% bilateral and 12% multifocal
- Histology relates to final outcome:
  - Favorable (95%)
  - Unfavorable (5%): Nuclear enlargement (>3-fold), hyperchromasia, abnormal mitoses, unfavorable marker of chemoresistance

DIFFERENTIAL DIAGNOSIS
- Clear cell carcinoma
- Rhabdoid tumor
- Neuroblastoma
- Multilocular cystic nephroma
- Mesioblastic nephroma
- Multicystic dysplastic kidney
- Renal cell carcinoma
- Renal medullary carcinoma

TREATMENT

GENERAL MEASURES
- Multimodality therapy combining surgery, chemotherapy, and radiation
- Treatment decisions based on staging
- Staging relies on anatomic extent of tumor (no genetic, histologic, or biomarkers); higher stages have worse prognosis and require more aggressive therapy
- 2 systems currently used: the NWTS/COG and SIOP; they are difficult to compare directly due to the fact that NWTS/COG is a prechemotherapy staging and SIOP post-chemoadjuvant therapy
- NWTS/COG: Commonly used in USA and Canada; based on surgical evaluation prior to chemotherapy
- SIOP: Commonly used in Europe, based on surgical findings following chemotherapy

MEDICATION

First Line
- SIOP: Studies favor preoperative chemotherapy for 6 wk with vincristine alone or vincristine followed by surgery. Histology and staging are potentially altered but the tumor response to chemotherapy is noted and aids in risk stratification
- Persistent biopsy is not recommended

ASSOCIATED CONDITIONS
- Congenital anomalies in 15% of Wilms tumors
  - GU anomalies: Renal anomalies, cryptorchidism, hypopigmentation, ureteral duplication, ambiguous genitalia (4%)
  - Hemihyperplasia (3%)
  - Aniridia (1%)
  - Denys–Drash syndrome (male pseudohemaphroditism, renal mesangial sclerosis, renal failure)

ONGOING CARE

PROGNOSIS

5-yr overall survival: 90%

4-yr postsurgery overall survival:

- Favorable histology: Stage II: 96%
  Stage III: 95%
  Stage IV: 90%

- Unfavorable histology: Stage II: 83%
  Stage III: 81%
  Stage IV: 72%

- Stage V: 55%

- Unfavorable histology: 12% of patients, but 50% of deaths

- Prognostic factors: Histology, stage, patient age (younger better prognosis, but less significant today due to improved treatments)

- Future treatment will include 1p and 16q loss of heterozygosity in the risk and treatment stratification

COMPLICATIONS

- Surgical:
  - Bowel obstruction (5.1%)
  - Hemorrhage (1.9%)
  - Wound infection (1.4%)
  - Injuries to other visceral organs (1%)

- Medical:
  - Renal impairment: 1% chance from surgical, chemotherapy, and/or radiation
  - Increased in bilateral disease with radiation
  - Unrelated disease risk in patients with disseminated disease

- Radiation:
  - Congestive heart failure in patients treated with doxorubicin and radiation
  - Doxorubicin cardiotoxicity

- Vincristine and doxorubicin-related:
  - Hepatotoxicity
  - Cardiotoxicity

- Vascular injuries (1.4%)

- Wound infection (1.9%)

- Hemorrhage (1.9%)

- highest risk in patients treated with both doxorubicin and radiation: occur in radiation field; mean 16.1 yr post therapy

- Radiation:
  - Short stature, muscle weakness, scoliosis
  - Highest risk in age: -12 mo
  - Thyroid disease and mammary tissue damage in chest radiation

- Pregnancy complications increased in females receiving high-dose abdominal radiation

FOLLOW-UP

Patient Monitoring

- Stages I-IV focal or diffuse anaplasia:
  - Stage II: Favorable histology and stage IV focal or diffuse anaplasia:
    - Abdominal/pelvic radiation: 10.8 Gy
    - Lung radiation: 12.0 Gy
    - Chemotherapy: vincristine, doxorubicin, and cyclophosphamide
  - Stages II-IV focal anaplasia:
    - Abdominal/pelvic radiation: 10.8 Gy
    - Chemotherapy: vincristine, doxorubicin, and cyclophosphamide

- Unfavorable histology:
  - Stage II: 83%
  - Stage III: 81%
  - Stage IV: 72%
  - Stage V: 55%

- Unfavorable histology: 12% of patients, but 50% of deaths

- Prognostic factors: Histology, stage, patient age (younger better prognosis, but less significant today due to improved treatments)

- Future treatment will include 1p and 16q loss of heterozygosity in the risk and treatment stratification

- Surgical:
  - Bowel obstruction (5.1%)
  - Hemorrhage (1.9%)
  - Wound infection (1.4%)
  - Injuries to other visceral organs (1%)

- Medical:
  - Renal impairment: 1% chance from surgical, chemotherapy, and/or radiation
  - Increased in bilateral disease with radiation

- Radiation:

  - Thyroid disease and mammary tissue damage in chest radiation
  - Pregnancy complications increased in females receiving high-dose abdominal radiation
SECTION II

Short Topics: A to Z

Section Editors: Deborah T. Glassman, MD
Alana M. Murphy, MD
11β-HYDROXYLASE (CYP11B1) DEFICIENCY

DESCRIPTION: Congenital 11β-hydroxylase deficiency (CYP11B1) causes Autosomal recessive disorder that manifests as childhood hypertension, hypokalemia, and muscle weakness. Low plasma renin activity is a hallmark. A deficiency in 11β-hydroxylase leads to low cortisol levels, high aldosterone levels, and adrenal hyperplasia. Affected females are not virilized and may have male-apparent genitalia. Males may be hypogonadal. Diagnosis is made by high levels of deoxycorticosterone and 11-deoxycortisol in serum or their tetrahydro-metabolites in a 24-hr urine. (See also Section I: “Disorders of Sexual Development [DSD].”)

TREATMENT:
- Oral hydrocortisone (10–20 mg/m2/day)
- Refractory hypotension treated with spironolactone, amiloride, and/or calcium channel blockers
- Surgical correction of ambiguous genitalia in females
- Prenatally treated with steroid administration to mother

5α-REDUCTASE DEFICIENCY

DESCRIPTION: An autosomal recessive disorder characterized by a 46XY male with external female phenotype at birth, normally developed Wolffian structures, and bilateral testes residing outside the abdominal cavity. The primary etiology is the loss of 5α-reductase activity in the prostate, seminal vesicles, and the epididymis. 5α-reductase activity is responsible for converting testosterone to dihydrotestosterone (DHT) during fetal development.

ACETAMINOPHEN ABUSE, UROLOGIC CONSIDERATIONS

DESCRIPTION: Bladder outlet obstruction can be defined only by pressure–flow measurement. The Abrams–Griffiths nomogram is an easy method of classifying these data to distinguish between the presence or absence of obstruction. Using the values for maximal flow and the corresponding voiding detrusor pressure, the Abrams–Griffiths nomogram can help determine whether bladder outlet obstruction is present.

The acrosome is a membrane-bound organelle covering the anterior 1/3 of the sperm head. This organelle contains numerous enzymes whose release, termed the acrosome reaction, is required for penetration of the hard zona pelucida of the ovum. It is hypothesized that human sperm bind to the ovum, after which the acrosome reaction is induced by 1 or more of the zona pelucida glycoproteins. Abnormalities of any aspect of this reaction may be a cause of male-factor infertility. Transmission electron microscopy, although the procedure of choice to detect acrosome reaction defects, is labor-intensive and expensive. This test may be recommended in cases of profound abnormalities of head morphology or in the setting of unexplained infertility in patients with poor IVF pregnancy rates. (See also Section II: “Semen Analysis, Technique, and Normal Values.”)

REFERENCE

ACTINOMYOSIS, RENAL
DESCRIPTION
Actinomycosis is a chronic granulomatous infection caused by a gram-positive anaerobic Actinomyces bacteria, usually A. israelii. No pathological findings are common; it can reach the kidney by hematogenous spread or instrumentation. Fibrils and fociules are common. The infection can present as pyrexia with negative urine culture. Imaging can reveal renal abscesses and hydrocephrosis, and the condition has been typically diagnosed postoperatively due to a renal mass prompting nephrectomy. It is diagnosed by gram-positive organisms on culture and prolonged incubation of bacteria. Microscopic exam of the organism can appear as yellow bodies called sulfur granules.

TREATMENT
• N-acetylcysteine has a clear role in preventing liver necrosis but not in the treatment of actinomyces-induced nephrotoxicity.
• Treatment focuses on supportive care, including management of volume status, blood pressure, and electrolyte balance.

REFERENCE

ACQUIRED RENAL CYSTIC DISEASE
DESCRIPTION
The development of renal cysts in patients with long-standing ESRD or severe chronic renal insufficiency. The cause is not known, but an accumulation of toxins unfiltered by dialysis is theorized. Usually asymptomatic. It can present with abdominal pain or hematuria. It is more common in males, and there is a 3–6 times greater incidence of renal cell carcinoma (RCC) compared to the general population (individual risk 4–7%). In dialysis-related RCC, neoplastic cells of acquired cystic disease-associated RCC are positive for alpha-methylacyl-CoA racemase (AMACR), but negative for cytokeratin (CK) 7. The cysts are slow to form and can be seen with a high incidence of metastasis. Risk increases with increased time on dialysis. (See also Section II: “Renal Cysts [Intimal, Peripelvic, Periureteral].”)

TREATMENT
• Close follow-up for early detection of malignancy (periodic imaging).
• Renal transplantation can reverse growth of cysts, but malignancy can still occur.

REFERENCE

ACROSOME REACTION ASSAY
DESCRIPTION
The acrosome is a membrane-bound organelle covering the anterior 1/3 of the sperm head. This organelle contains numerous enzymes whose release, termed the acrosome reaction, is required for penetration of the hard zona pelucida of the ovum. It is hypothesized that human sperm bind to the ovum, after which the acrosome reaction is induced by 1 or more of the zona pelucida glycoproteins. Abnormalities of any aspect of this reaction may be a cause of male-factor infertility. Transmission electron microscopy, although the procedure of choice to detect acrosome reaction defects, is labor-intensive and expensive. This test may be recommended in cases of profound abnormalities of head morphology or in the setting of unexplained infertility in patients with poor IVF pregnancy rates. (See also Section II: “Semen Analysis, Technique, and Normal Values.”)

REFERENCE

ADRENAL CALCIFICATIONS
ADRENAL FIBROMA, METANEPHRIC, PEDIATRIC
DESCRIPTION
Metanephric adenofibroma is a very rare benign tumor, first described as nephrogenic adenofibroma by Henningar and Bedworth in 1952. This tumor appears to affect predominantly young people (mean, 14 yo; range, 20 mo–35 yo). The most common symptom is hematuria, but a significant proportion of patients are asymptomatic. Polyuria is a peculiar incidental finding that resolves after resection of the tumor. The radiologic appearances are nondiagnostic and insubstantial from other solid pediatric renal tumors, particularly Wilms tumor. Histologically, this tumor is characterized by proliferation of benign-appearing mesenchymal cells surrounding multifocal nodules of immature epithelial cells. The latter cells show differentiation toward glandular and papillary structures. The mesenchymal component of metanephric adenofibroma closely resembles congenital mesothelial neoplasms in cytologic appearance. At present, all metanephric adenofibroma lesions should be excised to establish diagnosis, but no further adjuvant therapy is required.

REFERENCES

ADRENAL ANGIOMYOLIPOMA
DESCRIPTION
Angiomyolipoma arising from the adrenal. RCC contains more fat than adenoma. The etiology of this tumor is unknown. In a survey of 200 cases, the mean age was 20 yo. Angiomyolipoma is more common than adenoma, and most occur in the third and fourth decades of life. Histologically it consists of mature fat cells, smooth muscle cells, and thin-walled blood vessels. Management is identical to any adrenal mass: Assessment of functional status of the tumor with surgery if the pathological diagnosis of lesion is >5 cm (risk of malignancy and possibly bleeding). (See also Section I: “Adrenal Mass”, and Section II: “Adrenal: Myelolipoma [Adrenal Myelolipoma].”)

REFERENCE

ADRENAL CALCIFICATIONS
DESCRIPTION
Adrenal calcifications may be the result of hamartoma (secondary to trauma, venous thrombosis, stress, or bleeding diathesis), infective (usually granulomatous diseases), or may be associated with different tumors. Necrosis and calcifications are more common in association with adenocarcinoma but are not diagnostic. Bilateral calcified adrenal glands may be seen in adenocarcinoma or secondary Addison disease. Calcifications may be detected on MRI; however, because of their susceptibility artifact but are much better appreciated on CT images.

REFERENCE
ADRENAL CYSTS AND PSEUDOCYSTS

**ADRENAL CYSTS AND PSEUDOCYSTS**

**DESCRIPTION**
A cyst (0.064–0.18” in autopsy studies) is a cavity filled with fluid. Most are asymptomatic. These cysts can cause GI discomfort, pain if large, and even an acute abdomen with rupture or infection. Four major types are recognized: Endocrinologic, pseudocyst, epithelial, and parasitic; in order of decreasing incidence. Pseudocysts arise primarily from Echinococcus granulosus infection. Adrenal pseudocysts are thought to result from infarction or hemorrhage of a cyst or tumor.

**TREATMENT**
• >3.5 cm: Observation with serial imaging (US or CT or MRI).

**REFERENCE**

**ADRENAL CYTOMEGALY**

**DESCRIPTION**
Found infrequently in children and adults who considered a benign mass lesion, the condition is seen often in Beckwith–Wiedemann syndrome. Other possible associations include hemolytic disease of the newborn, erythroblastosis fetalis, and congenital rubella. It is characterized by the presence of large polyhedral cells with eosinophilic granular cytoplasm and enlarged nuclei in the adrenal cortex. Adrenal cytomegaly rarely forms cysts. This condition is thought to be a degenerative process but not a malignancy, possibly caused by a physiologic condition resulting from functional capacity and proliferation of adenocytes.

**REFERENCE**

**ADRENAL CYSTIC HYPOPLASIA**

**DESCRIPTION**
Incidentally discovered adrenal lesion: Whether it is functioning and whether to observe, screen and do follow-up studies.

**REFERENCE**

**ADRENAL HYPOPLASIA**

**DESCRIPTION**
Reduced ACTH production can result in hypoplasia of the adrenal gland (secondary adrenal hypoplasia); this can occur as a result of lack of pituitary trophic signaling, such as in pituitary agenesis. Congenital adrenal hypoplasia (primary) is an inherited disorder, with several forms identified. The major form of adrenal hypoplasia is Klinefelter syndrome and it is to the BAX-1 (46RH) gene. This gene is in close proximity to other genes encoding for: tyrosine kinase and Osurne. (Both associated with adrenal hypoplasia). Hypogonadotropic hypogonadism is also a common finding. It typically presents in the neonatal period or when adrenal crisis (dehydration, hypotension, hyperkalemia, hypoglycemia, hypoglycemia). Disorders of the external genitalia may include micropenis, undescended testes, or hypospadias. It can be detected by biochemical testing (serum cortisol, corticotropin releasing hormone (CRH) stimulation test, etc). Adrenal renal adrenal screening can also detect adrenal hypoplasia.

**TREATMENT**
Treatment is replacement of adrenal hormones.

**REFERENCE**

**ADRENAL HEMORRHAGE**

**DESCRIPTION**
Adrenal hemorrhage (AH) is a blood echogenic mass. CT scans, and the prevalence increases with age. Most are asymptomatic. Some symptoms include fever, flank or abdominal pain, tachycardia, nausea, vomiting, respiratory distress, and weakness. Ultrasound may be an incidental finding during imaging. AH may result from multiple mechanisms: Stress, sepsis (Winterbottom-Friedenreich syndrome), anticoagulation-related hemostasis, vascular spasm, adrenal venous thrombosis, or heparin-associated thrombocytopenia. Workup may show decreased hemoglobin and electrolytes in order of triphasic incidence. Hypokalemia in 56% of Bilateral AH.

**TREATMENT**
Include replacement of fluids, electrolytes, and blood if anemia is significant. Patients should be started on steroid replacement if adrenal insufficiency is suspected. Surgical exploration may be necessary for uncontrollable hemorrhage, uncertain diagnosis, or if obvious formation is suspected.

**REFERENCE**

**ADRENAL HYPOPLASIA**

**DESCRIPTION**
Reduced ACTH production can result in hypoplasia of the adrenal gland (secondary adrenal hypoplasia); this can occur as a result of lack of pituitary trophic signaling, such as in pituitary agenesis. Congenital adrenal hypoplasia (primary) is an inherited disorder, with several forms identified. The major form of adrenal hypoplasia is Klinefelter syndrome and it is to the BAX-1 (46RH) gene. This gene is in close proximity to other genes encoding for: tyrosine kinase and Osurne. (Both associated with adrenal hypoplasia). Hypogonadotropic hypogonadism is also a common finding. It typically presents in the neonatal period or when adrenal crisis (dehydration, hypotension, hyperkalemia, hypoglycemia, hypoglycemia). Disorders of the external genitalia may include micropenis, undescended testes, or hypospadias. It can be detected by biochemical testing (serum cortisol, corticotropin releasing hormone (CRH) stimulation test, etc). Adrenal renal adrenal screening can also detect adrenal hypoplasia.

**TREATMENT**
Treatment is replacement of adrenal hormones.

**REFERENCE**

**ADRENAL INCIDENTALOMAS**

**DESCRIPTION**
Incidentally discovered adrenal lesions — called “adrenal incidentalomas” — are by-products of increased availability and use of advanced imaging. Adrenal masses are found in approximately 4% of patients undergoing abdominal CT scans, and the prevalence increases with age. Most are nonfunctional, benign adenomas. It is important to consider 2 questions in the evaluation of an adrenal incidentaloma: Whether it is functioning and whether it is malignant. Differential diagnosis includes benign nonfunctioning adenoma, pheochromocytoma, hormonally active tumors such as pheochromocytoma, primary hyperaldosteronism, and Cushing disease (nodular hyperplasia); myelolipoma and malignancies including adrenocortical carcinoma; or metastasis from lungs, breast, colon, kidney, melanoma, or lymphoma. (See also Section 1: “Adrenal Mass.”)

**REFERENCE**

**ADRENAL MYELOLIPOMA**

**ADRENAL MYELOLIPOMA**

**DESCRIPTION**
Referred to as myelolipoma and myelolipoma in the literature, this rare, usually nonfunctioning lesions are composed of adipose and hematopoietic cells. Myelolipomas may be extramedullary hematopoiesis. It is rarely metabolically active (Cushing or Conn syndrome) and usually asymptomatic, except when very large or if hemorrhage occurs. They mostly occur in the adrenal glands, but extra-adrenal myelolipomas have been reported (pulmonary, retroperitoneum). It can be diagnosed radiographically and is more typically incidentally discovered on imaging or autopsy. Ultrasound shows a highly echogenic mass. CT demonstrates focal densities near that of fat (Hounsfield units of ~30 to ~115). MRI T1-weighted images demonstrate high signal intensity, whereas T2-weighted images are moderately intense. The main diagnostic similarity is well differentiated liposarcoma. (See also Section 1: “Adrenal Mass.”)

**TREATMENT**
Excision if symptomatic or if diagnosis cannot be confirmed radiographically or on needle biopsy.

**REFERENCE**

**ADRENAL ONSCYCTOMY**

**DESCRIPTION**
Gonadal neoplasms of the adrenal study, unlike that of the kidney, are rare with only 147 cases described. 80–90% of lesions are nonfunctional and only 10–20% of lesions show malignant elements. Typically occurs from 27–72 yr of age. Most common in women (2:1 ratio compared to men) and the left adrenal gland (3:1 ratio compared to the right). Histologically, lesions are highly granular and eosinophilic due to an abundance of mitochondria. Grossly, they are large, well-rounded, and encapsulated with an average diameter of 8 cm (2–20 cm). When cross sectioned, they have a brown, yellow, or mahogany appearance. Mitoses include breast (most common), lung, kidney, stomach, pancreas, and melanoma. (See also Section 1: “Adrenal Mass.”)

**REFERENCE**
the adrenal lesion can be performed either laparoscopically or using an open technique. If benign, the prognosis is excellent. If malignant, there is a 20–35% 5-yr survival rate. (See also Section I: “Adrenal Insufficiency.”)

REFERENCE

ADRENAITALIS

DESCRIPTION: An inflammation of the adrenal gland that can lead to primary adrenal insufficiency (Addison disease), which accounts for 80% of cases. Tuberculosis is the 2nd leading cause, with the balance made up by fungal infections, hermaphrodite, metastatic neoplasms, sarcoidosis, amyloidosis, and adrenal leukodystrophy. Autoimmune adrenitis can be associated with thyroiditis, diabetes mellitus, pernicious anemia, vitiligo, hypothyroidism, and mucocutaneous candidiasis (autoimmune polyendocrine syndrome type I), also known as candidiasis-hypothyroidism-Addison disease-syndrome), or with autoimmune polyendocrine syndrome type 2 (also known as Schmidt syndrome). HIV with opportunistic CMV adrenitis accounts for an increasing number of cases. (See also Section I: “Adrenal Insufficiency, acute (adrenal crisis) and “Addison Disease.”)

TREATMENT
• Replacement of adrenal and other hormones, as necessary
• Treatment of underlying cause

REFERENCE

ADRENOCORTICAL DISEASE, PRIMARY PIGMENTED NODULAR

DESCRIPTION: Primary pigmented nodular adrenocortical disease (PPAD) is a rare AC syndrome independent form of Cushing syndrome, accounting for ~1% of Cushing syndrome patients. Hypercortisolism is resistant to a dexamethasone suppression test. Typically, bilateral adrenal glands are involved with gross appearance of multiple nodules of varying sizes and pigmented colors. Histologically, the nodules are circumscribed, unencapsulated, and comprised of polygonal cells with an eosinophilic appearance. 25% of patients manifest Carney complex, which includes spotty skin pigmentation, endocrine tumors, and myxoid desmoids. Treatment requires bilateral adrenalectomy as unilateral and partial adrenalectomy has resulted in recurrence. (See Section I: “Cushing Disease and Syndromes.”)

REFERENCE

ADRENODENDRAL SYNDROME

DESCRIPTION: This is the most common cause of disorders of sexual development (DSD) (formerly ambiguous genitalia), caused by an internal error of masculinization involving androgen synthesis. At birth it is a defect in any of the 5 enzymes involved in the cortisol biosynthetic pathway (21-hydroxylase, 11-hydroxylase, 3-hydroxysteroid dehydrogenase, 20,22-desmolase, and 17-hydroxylase), which may result in CAH. Usually presents with an autosomal recessive inheritance. (See also Section I: “Disorders of Sexual Development (DSD).” Section II: “Congenital Adrenal Hypertrophy.”)

SYNONYMS
• CAH
• Female pseudohermaphrodite
• Male pseudohermaphrodite

COMPLICATIONS
• For untreated females:
  – Premature pubic and axillary hair development
  – Rapid osteopathic maturation, premature epiphyseal closure, short adult stature
  – No breast development or menstruation
• For untreated males:
  – Sexual and somatic precocity within 1st 2 yr of life
  – Premature epiphyseal closure, short adult stature
  – Untimely male and female pubertal and secondary sex characteristic
  – Progressive weight loss, dehydration within 1st few weeks of life

TREATMENT
• Early diagnosis with ascertainment of correct sex and prevention of salt wasting and metabolic complications
• Steroid replacement with cortisone, hydrocortisone, or dexamethasone as needed
• Surgical genital reconstruction may be necessary early in life, based on specific findings

REFERENCES

ADRENOLUEKYOSTROPHY

DESCRIPTION: Rare, X-linked recessive metabolic disorder occurring in boys, and characterized by adrenal atrophy and widespread, diffuse cerebral demyelination. It produces mental deterioration, cortical spinal tract dysfunction, and cortical blindness. There is a lab evidence of adrenal cortical dysfunction. 2 phenotypes, with onset in childhood or young adulthood, exhibit hypogonadism. Death inevitably occurs within months of onset. A defect is theorized in peroxisomes, which handle long-chain fatty acids. Concept’s (or mixture of glycerol and long-chain fatty acids) has been tried in this disease, with some delay in neurologic symptoms. Bone marrow transplantation is under study.

REFERENCE

SYNONYM
Formerly Glyeryl trierucate oil

REFERENCE

AGING MALE SURVEY

DESCRIPTION: The Aging Male Survey (AMS) is a questionnaire developed to detect hypogonadism in adult men. It has 3 domains: Psychological, Somatic-vegetative, and Sexual. The minimum and maximum scores are 5 and 25, respectively, for the Psychological and Sexual domains and 7 and 35 for the Somatic-vegetative domain. The higher the score, the more severe the symptoms. The AMS has been shown to have a sensitivity (83%) and specificity (99%) similar to those of the shorter ADAM Survey. (See also Section I: “Andropause [Late Onset Male Hypogonadism]” and Testosterone, Decreased [Hyponogonadism]. Section II: “Androgen Deficiency in the Aging Male (ADAM) and ADAMS Survey.”)

REFERENCE

AL GHIRAB CORPORAL SHUNT

DESCRIPTION: A surgical treatment for the management of priapism refractory to penile aspiration. A small transverse incision is made on the dorsum of the glans. A section of septum between the glans corpora and the corpora cavernosa is removed to create a shunt. (See also Section I: “Priapism” and Section II: “Al Ghorab Corporal Shunt With Burnett “Snake” Maneuver.”

REFERENCE

AL GHIRAB CORPORAL SHUNT WITH BURNETT “SNAKE” MANEUVER

DESCRIPTION: A modification of the Al Ghorab distal corporal glansular shunt for priapism. The Burnett “snake” modification involves passing a 7/8 Hegar dilator through the amputated glans tip of the corpus cavernous bladder. The dilator is passed to the proximal lesion of the corpus cavernous laterally on each side to avoid urothelial injury. Milking of ischemic blood and clot is performed until bright red blood is visualized. A study of 10 patients with a mean follow-up of 7 mo reported that 8 men had no recurrence of priapism. Of the 6 men who had normal erectile function preoperatively, 2 had partial erectile function postoperatively.

REFERENCE
ALAGILLE SYNDROME

DESCRIPTION
An autosomal dominant disorder associated with abnormalities of the liver, heart, eye, skeleton, and kidneys. A characteristic facial appearance is also seen. Renal abnormalities are not specific but include diploia and renal failure. This autosomal dominant disorder is mapped to chromosome 20; it is treated by renal replacement therapy as needed.

SYNONYM
Alagille-Watson syndrome

REFERENCE

ALKALINE PHOSPHATASE, UROLOGIC CONSIDERATIONS

DESCRIPTION
As an enzyme produced in many tissues, such as bone, liver, placenta, and intestine, alkaline phosphatase can monitor the progression of metastatic cancer to bone (such as prostate cancer). Bone (or core) can be distinguished from other sources by its heat lability compared with other forms. This test has also been recommended by some authors as a useful tool for monitoring antineoplastic agents.

REFERENCE

ALKAPTONURIA

DESCRIPTION
An inherited (dominantly expressed) disorder of metabolism of phenylalanine and tyrosine metabolism wherein homogentisic acid (HGA) accumulates in the body and is excreted in a large amount in the urine. If allowed to stand, the urine gradually turns dark (black urine disease). Alkalai can accelerate this process. Ochronosis (deposition of a bluish-black pigment noted in the connective tissue) may lead to arthropathy. Ocular: interstitial, renal failure occurs, opacities, with long-standing disease. Even more rarely, HGA stones can occur. It is caused by a single gene defect, causing absence of HGA release. It is treated by dietary restriction of phenylalanine and tyrosine metabolism of phenylalanine and tyrosine metabolism.

SYNONYM
Bluish-black urine disease

REFERENCE

ALLOPURINOL HYPERSENSITIVITY SYNDROME (AHS)

DESCRIPTION
2% of patients treated with allopurinol will develop minor adverse reactions, including drug eruption, pruritic maculopapular exanthema or minor vasculitis, which often disappear after cessation of treatment. In contrast, AHS is a life threatening and includes at least 2 of the following major criteria:
• Decreasing renal function
• Acute heparinovascular injury
• Cutaneous rash including erythema multiforme (EM), generalized morbilliform eruptions, generalized exfoliative dermatitis (GED), or Steven-Johnson syndrome/ebullis epidermal necrolysis (SS/EN). Diagnostic criteria may also include 1 of the above and at least 1 of the following minor criteria:
  • Fever
  • Eosinophilia
  • Leukocytosis

TREATMENT
Nebulizer alternative for patients with AHS

REFERENCE

ALPLOPOLY

DESCRIPTION
A poorly understood and clinically insignificant condition marked by the loss and subsequent regrowth of pubic hair, possibly due to tight-fitting undergarments.

REFERENCE

- (ALPHA) FETOPROTEIN

DESCRIPTION
A single-chain glycoprotein (MW 70,000) that primarily aids in the management of testicular cancer. It is normally produced by the liver, yolk sac, and fetal testis. Adult level is 5.0–6.0 ng/mL. Serum a-fetoprotein (AFP) levels are normally elevated in the 1st 8 mo of life. The normal adult level is <5 ng/mL. This can be elevated in 39% of cases of embryonal cell carcinoma, 44% of neuroblastoma, and 64% of yolk sac tumors. Other reasons for elevation include resectable hepatocellular carcinoma, hepatocellular neoplasm, fetal death, aplasia termalis, and some cases of benign hepatic disease.

REFERENCE

ALPORT DISEASE/SYNDROME

DESCRIPTION
Alport disease/syndrome consists of hereditary nephritis, high-frequency neural hearing loss, and ocular abnormalities. It can present as hematuria, proteinuria, or anemia. Familial abnormality is crucial in diagnosis. The nephritis is progressive, usually resulting in renal failure by the 3rd decade. Males are more severely affected. It is caused by a genetic mutation on a single locus on the X chromosome, with altered type IV collagen production. Treat with renal replacement therapy, as needed.

REFERENCE

ALSTRÖM–EDWARDS SYNDROME

DESCRIPTION
A progressive autosomal recessive genetic disorder affecting multiple organ systems. It may be detected at birth or in early childhood. Clinically, patients with Alstrom syndrome develop cone–rod dystrophy leading to eventual blindness, have sensorineural deafness, and normal intelligence. Patients develop obesity, endocrine disturbances such as type 2 diabetes mellitus, delayed cardiomyopathy, and progressive renal and hepatic failure. Alstrom syndrome is caused by specific mutations in the ALMS1 gene, located at chromosome 2p13. No specific treatment is available for infertility; renal replacement therapy is indicated as needed.

SYNONYM
Alston syndrome

REFERENCE

ALZHEIMER DISEASE, UROLOGIC CONSIDERATIONS

DESCRIPTION
Alzheimer disease is the principal cause of dementia in the elderly patient population. The urologic manifestations include urinary incontinence, decreased bladder, and erectile dysfunction (ED). Patients may be difficult to treat due to limited cooperation with the treatment plan; toileting schedules can help with early incontinence episodes. Often considered a case of “functional” urinary and fecal incontinence. Current theories regarding the etiology of Alzheimer disease revolve around cortical cholinergic loss. This may also make the treatment of urologic manifestations even more difficult by limiting the use of anticholinergic agents. Rule out other concomitant causes before ascribing urinary tract problems to this disease specifically. (See Section I: “Incontinence, Urinary, Adult Male”; Section I: “Incontinence, Urinary, Adult Female.”)

REFERENCE

AMBIGUOUS GENITALIA

DESCRIPTION
DSO (Disorders of sexual development) refers to a child born with a congenital discrepancy between external genitalia, gonads, and chromosomal sex. In 2006, consensus conference stated that the potentially reparative terms “pseudohermaphrodite,” “hermaphrodite,” and “intersex” be replaced by the more appropriate diagnostically accurate term “DSD.” It is recognized that some DSDs present with abnormalities of the external genitalia. These abnormalities that prompt evaluation occur in approximately 1 in 4,500 live births. These findings may include may

AMERICAN ASSOCIATION FOR THE SURGERY OF TRAUMA (AAST) ORGAN SEVERITY SCALES: GENITOURINARY INJURIES

DESCRIPTION

Numerous classifications of traumatic injuries exist, but the most widely used and accepted classification was developed by the American Association for the Surgery of Trauma’s Organ Injury Scaling Committee. (See also Section I: “Bladder Trauma, Perineum, Trauma; Renal Trauma, adult; Urethra, Trauma; Urethra, Trauma.”

REFERENCE

AMINOCIDURIA

DESCRIPTION

Excretion of an overabundance of amino acids in urine, more often due to an inherent error of metabolism. Aminociduria is found in association with renal tubular acidosis, Fanconi syndrome, and other primary renal tubular disturbances. It may also occur secondary to other diseases that affect the kidneys, such as diabetes mellitus (DM) and diabetes insipidus (DI).

REFERENCE

AMMONIUM CHLORIDE LOADING TEST

DESCRIPTION

An acid loading test to rule out distal renal tubular acidosis. Performed by giving 0.1 g/kg ammonium chloride oral solution over 45 min after a 6 hr fast. 100 ml of water are given every hour during the test. Urine pH is measured hourly for 4 hr. Serum bicarbonate values are taken at hours 2 and 4 to ensure adequate acidification (pH<5.6). The normal result is urine pH <5.4; distal RTA exists if pH >5.4. (See also Section II: “Renal Tubular Acidoses.”)

AMERSTAD AND BETHESDA CRITERIA FOR LYNCH SYNDROME

DESCRIPTION

Criteria have been developed to aid in the diagnosis of hereditary nonpolyposis colorectal cancer (HNPCC or Lynch syndrome). Lynch syndrome caused by a germline mutation in a mismatch repair gene and associated with tumors exhibiting microsatellite instability (MSI), is

REFERENCE

Used to treat ureteropelvic junction obstruction. The UPJ is declared, and the ureter is reimplanted into the renal pelvis. The widely spatulated ureter is reanastomosed to the renal pelvis with the widely spatulated end of the UPJ being excised. Normal anal sphincter function is restored. (See also Section II: “Bladder Trauma, Perineum, Trauma.”)

REFERENCE

ANAL SPHINCTER TONE AND SENSATION, UROLOGIC CONSIDERATIONS

DESCRIPTION

Anal sphincter tone is a vital part of the GU evaluation, especially in a person with new-onset urinary incontinence. Normal anal sphincter tone is a function of somatic fibers traveling over S2–5 in the pudendal nerve. A hypotonic sphincter suggests a lower motor neuron lesion, whereas a hypertonic sphincter may be an upper motor neuron lesion. The loss of voluntary contraction of the sphincter suggests interruption of centrally directed fibers somewhere between the motor strip of frontal cortex and the pudendal nerve. The bulbocavernous reflex (BCR), which is widely used in evaluating urinary incontinence and ED, requires adequate sphincter contraction in response to squeezing the glass of water.

REFERENCE

ANDERSON-HYNES PYELOPLASTY

DESCRIPTION

Used to treat ureteropelvic junction (UPJ) obstruction. The UPJ is declared, and the ureter is reimplanted into the renal pelvis. The widely spatulated ureter is reanastomosed to the renal pelvis with interrupted chromic suture, and the excised renal pelvis is closed with simple or running suture. After nephrectomy, a ureteral stent is placed. (See also Section II: “Bladder Trauma, Perineum, Trauma.”)

ANDREWS PROCEDURE (HYDROCELE)

DESCRIPTION
A technique described in 1907 where the hydrocele sac at the superior portion of the testis is incised 2–3 cm. This step is followed by excision of the edges of the testis, which is wrapped around the cord structure.

SYNONYM
Bottle Operation

REFERENCE

ANDREWS DEFICIENCY IN THE AGING MALE (ADAM) AND ADAM QUESTIONNAIRE

DESCRIPTION
Previously referred to as andropause, this has more recently been described as ADAM. The onset of ADAM is unpredictable, and its manifestations are subtle and variable. It is associated with a decrease in testosterone, but also with decreased growth hormone, insulin, and dehydroepiandrosterone (DHEA). Clinical manifestations include fatigue, depression, decreased libido, and erectile dysfunction (ED), as well as changes in cognition and mood. The ADAM questionnaire is a screening tool to detect late-onset andropause, with a sensitivity and specificity of 88% and 60%, respectively, compared with serum bioavailable testosterone levels. A positive answer represents yes to questions 1 or 7 or to any of the other questions.

The Androgen Deficiency in Aging Male (ADAM) Questionnaire

Yes No 1. Do you have a decrease in libido (sex drive)?
Yes No 2. Do you have a lack of energy?
Yes No 3. Do you have a decrease in strength and/or endurance?
Yes No 4. Have you lost height?
Yes No 5. Have you noticed a decreased enjoyment of life?
Yes No 6. Are you sad and/or grumpy?
Yes No 7. Are your erections less strong?
Yes No 8. Have you noticed a recent deterioration in your ability to play sports?
Yes No 9. Are you falling asleep after dinner?
Yes No 10. Has there been a recent deterioration in your work performance?

ANDROGEN DEPRIVATION SYNDROME (ADS)/ METABOLIC SYNDROME

DESCRIPTION
Long-term androgen deprivation therapy (ADT), for the treatment of prostate cancer, results in hypogonadism and increased risk of type 2 diabetes mellitus. Furthermore, death from cardiovascular disease (CVD) is the most common cause of prostate cancer-related death in these men. ADS is a spectrum of adverse effects that includes flushing, impotence, loss of libido, emotional lability, anxiety, hyperglycemia, increased triglycerides and cholesterol, muscle atrophy, decreased muscle strength, testosterone atrophy, osteoporosis, depression, anxiety, malaise, fatigue, and memory difficulties. Andrological syndrome defined by the NIH Adult Treatment Panel III criteria is also part of this spectrum and may include abdominal obesity, hypertension, hyperglycemia, hyperinsulinemia, elevated HDL cholesterol, and hypertriglyceridemia. Treatment of the metabolic syndrome includes:

- Management of underlying causes (metabolically and physically inactive): Weight management, increased physical activity
- Treat lipid and nonlipid risk factors if they persist
- Treat hypertension
- Management of underlying causes (metabolically and physically inactive): Weight management, increased physical activity
- Treat lipid and nonlipid risk factors if they persist
- Treat hypertension
- Management of complete (severe) androgen insensitivity is important to target the optimal timing of goserelin acetate. Because the testes produce estradiol, which results in appropriate changes for the female phenotype, it is considered by many preferable to leave the testes in situ until pubertal development is complete. In partial androgen insensitivity, the external genitalia may be ambiguous at birth, but the prototypical phenotype is characterized by perineoscrotal hypospadias, micropenis, and a bifid scrotum. The testes may also be undescended.

Clinical Features of Complete Androgen Insensitivity Syndrome

- Karyotype 46, XY
- Inheritance X-linked recessive
- External genitalia Ambiguous with blind vaginal pouch, undermasculinized, isolated hypoplasia, and primary amenorrhoea
- Wolffian duct derivatives Absent or vestigial
- Gonads Bilateral Tests
- Hormone and metabolic profile Testosterone levels; increased estradiol (Female reference range), FSH levels often normal or slightly increased. Resistance to androgenic and metabolic effects of testosterone

REFERENCES

ANDROGEN INSensitivity SYNDROME (AIS; OR ANDROGEN RESISTANCE SYNDROME, COMPLETE (CAIS) AND PARTIAL (PAIS))

DESCRIPTION
Androgen insensitivity is a disorder of androgen action and a common form of 46,XY DSD. Mutations in the androgen receptor lead to variable defects in virilization or infertility in 46,XY males with testes and normal testosterone formation. Clinical presentation ranges from phenotypic women to variable defects in virilization or infertility in 46,XY males with testes and normal testosterone formation. Clinical presentation ranges from phenotypic women to variable defects in virilization or infertility in 46,XY males with testes and normal testosterone formation. Clinical presentation ranges from phenotypic women to variable defects in virilization or infertility in 46,XY males with testes and normal testosterone formation. Clinical presentation ranges from phenotypic women to variable defects in virilization or infertility in 46,XY males with testes and normal testosterone formation.

Clinical Features of Partial Androgen Insensitivity Syndrome

- Karyotype 46, XY
- Inheritance X-linked recessive
- External genitalia Ambiguous with blind vaginal pouch, undermasculinized, isolated hypoplasia, and primary amenorrhoea
- Wolffian duct derivatives Absent or vestigial
- Gonads Bilateral Tests
- Hormone and metabolic profile Increased LH and testosterone concentrations; increased estradiol (for female reference range). FSH levels may be normal or slightly increased. Partial resistance to androgenic and metabolic effects of testosterone

REFERENCES
ANTIOVARYAN WITHERDRAWN SYNDROME (FLUTAMIDE WITHERDRAWN SYNDROME)

REFERENCE

ANDROGEN/ANABOLIC STEROID ABUSE

DESCRIPTION

Androgens are steroid hormones that include testosterone and its derivatives, including androstenedione, DHT, and dromestosterone. In the medical realm, androgens at physiologic doses treat androgen deficiency due to hypothalamic, pituitary, or testicular disorder of genetic or acquired etiology. The use of androgens at supra-physiologic doses greatly enhances muscle strength, size, and performance, thus promoting its abuse most notably in power sports and body building. While banned by all major sports organizations, androgen abuse is rampant and has been linked to several high-profile athletes. Androgen abuse is a frequent cause of male infertility by suppression of Leydig cell production of testosterone, which results in delayed spermatogenesis. Abnormalities in sperm motility and morphology are commonly seen, and usually recover spontaneously within 4 mo after cessation of abuse.

REFERENCE

ANGIOKERTATOMA OF FORDYCE (PENILE AND SCROTAL ANGIOKERTOMAS)

DESCRIPTION

Vascular malformation of subepidermal blood vessels with an overlying epidermal proliferative reaction. Capillary ectasia is present in the papillary dermis. Typically, numerous dark red to blue dome-shaped papules are linearly arranged on the scrotum and, less commonly, on the penis. In women, 1 larger vulvar papule is typical. Dark red to blue dome–shaped papules are linearly present in the papillary dermis. Typically, numerous subepidermal blood vessels with an overlying eosinophils, and (4) lymphoid infiltrates. These are found: (1) Vacuolated histiocytoid cells, (2) tumor histiocytoid hemangiomas in which 4 features are necessary. Adjuvant radiation may be useful; chemotherapy for adjuvant or metastatic disease is not usually effective.

REFERENCE

ANGIOLUMPHOID HYPERPLASIA, PENILE

DESCRIPTION

A subtype of a broad class of histiocytoid hemangiomas in which 4 features are found: (1) Vasculur histiocytoid cells, (2) tumor vessels that are thick-walled or capillaries consisting of only of histiocytoid endothelial cells, (3) interstitial eosinophils, and (4) lymphoid infiltrates. These are usually confluent to the skin of 1 area of the body.

SYNONYMS

• Fordyce dots (or atypical seborrheic granule)
• Inflammatory angiomatous nodule
• Subcutaneous angiofibroplasia with eosinophilia
• Epithelial hemangioma
• Intravascular atypical vascular proliferation

TREATMENT

Local surgical resection or laser (CO2) ablation.

REFERENCE

ANGIOMYOMA, PERINEAL

DESCRIPTION

Rudimentary lesion of the pelvis with tissue, but may vary due metastasis. Characterized by slow, infiltrative growth. May present as mass in the pelvis. Histologically, demonstrates wavy collagen fibers related to the myxoid change. Multiple prominent blood vessels are also seen. It occurs mainly in females and can be quite locally aggressive, with frequent local recurrence. Treatment is through wide local excision with close postoperative monitoring.

REFERENCE

ANGIOSARCOMA, GENITOURINARY

DESCRIPTION

A very rare malignancy that greatly appears as a well-circumscribed mass or diffusely fungating tumor that may involve any organ. Microscopically, angiosarcoma shows numerous vascular channels. It stains positively for factor V, immunohistochemically. These sarcomas can be widely metastatic and have persistent local recurrence. Bladder angiosarcoma has been reported postirradiation for treatment of other malignancies; chronic lymphedema, foreign bodies, and other causes have been implicated.

TREATMENT

Radical resection of affected area (penectomy, radical resection of affected area). Such a patient may present as mass in the pelvis. Histologically, demonstrates wavy collagen fibers related to the myxoid change. Multiple prominent blood vessels are also seen. It occurs mainly in females and can be quite locally aggressive, with frequent local recurrence. Treatment is through wide local excision with close postoperative monitoring.

REFERENCE

ANTERIOR URETHRAL VALVES

DESCRIPTION

Much less common than posterior urethral valves, this condition is characterized by obstruction of the anterior urethra, usually associated with the posterior urethra. It is caused by a diverticulum acting as valves, although corks without diverticulum have been reported. It usually presents with voiding symptoms or bulging diverticulum on the normal shaft with voiding. Diagnosed by VCUG and renal ultrasound. Retropubic urethropexy may miss the valve. It may be associated with reflux, but less so than with PUV. Renal deterioration is less common than with PUV.

TREATMENT

• Bilateral catheter if urethrae occurs
• Endoscopic valve fulguration or single-stage urethroplasty if urethra is adequate
• Staged urethropexy for large diverticulum
• Vescicoureteral reflux or persistent azotaemia

REFERENCE

ANTIOVARYAN WITHERDRAWN SYNDROME (FLUTAMIDE WITHERDRAWN SYNDROME)

DESCRIPTION

A decrease of PSA levels occurs in 15–40% of patients upon withdrawal of nonsteroidal antiovars in those treated for advanced prostate cancer with total androgen blockade that is rarely
APPROACH TO GENITAL ULCERS

APHTHOUS ULCER, EXTERNAL GENITALIA

DESCRIPTION

Aphthae are localized, painful, shallow, round to oval ulcers often covered by a gray to white, central, superficial, necrotic layer with a pale red border and an erythematous halo. Complex aphthosis involves almost 10% of the oral and/or genital mucosa. Those involving both oral and genital aphthae are termed constant, multiple, oral or oral and genital aphthae. When a disruption occurs in the blood–testis barrier; they may be a cause of infertility. Causes can include ductal obstruction (i.e., varicocele), infection, cryptorchidism, and warfarin, but are often idiopathic. Serum antisperm antibody levels are not as useful as antibodies in the semen, which can be measured by immunobead testing. The higher the percentage of sperm binding to the bead, the lower the probability of pregnancy. Scoring varies by lab, but normal is generally considered to be <10% of sample binding to the bead. Condylomas, antibiotics, steroids, and sperm washing have all been utilized, with variable results. Presently, assisted reproductive techniques (ARTs) such as in vitro fertilization are most effective. See also Section II: “Infertility”; Section II: “Semen Analysis, Abnormal Findings and Techniques”; “Semen Analysis, Technique and Normal Values.”

REFERENCE

ARTEMIOVIRUS MALFORMATION

DESCRIPTION

Arensiviruses are in the family Arenaviridae, order Mononegavirales, and are characterized by lipid-enveloped, pleomorphic particles. Arenavirus is a genus that consists of 2 species: Lassa virus and Marburg virus. Arenaviruses are commonly transmitted to humans by infected rodents or bats. Human-to-human transmission can also occur. The current scientific understanding suggests that Arenaviruses are not a major human health concern. However, in 2013, a novel human arenavirus emerged which has caused multiple outbreaks in Sierra Leone, Guinea and Liberia. The disease is characterized by a fever, severe headache, and respiratory tract infection. The disease has a high mortality rate. The arenavirus is transmitted through the bite of infected rodents, and the virus is currently being studied for potential vaccine development.

REFERENCES

ARTERIOVENOUS MALFORMATION (AVM)

DESCRIPTION

Arteriovenous malformations (AVMs) are rare vascular anomalies characterized by the coexistence of arterial and venous blood vessels lacking an intermediate capillary bed. AVMs can occur anywhere in the body, but the most common sites are the brain, scalp, and lower extremities. They can cause local effects such as pain, swelling, or disfigurement, as well as systemic effects such as organ dysfunction and bleeding. Treatment options for AVMs include surgical resection, embolization, and radiosurgery. The goal of treatment is to eliminate or reduce the size of the AVM, thereby improving symptoms and preventing complications.

REFERENCES

ARTERIOVENOUS FISTULA (AVF), RENAL OR ARTERIOVENOUS MALFORMATION (AVM)

DESCRIPTION

Racial AVF or AVM are uncommon lesions. They can be congenital, acquired, or idiopathic. Most (70%) are symptomatic and occur as a result of renal biopsy, blunt or penetrating trauma,
ASPERGILLOSIS, GENITOURINARY

DESCRIPTION
Only Candida infections are more common opportunistic infections in the urologic population than aspergillosis. It affects patients with diabetes and malignancy, and immunosuppressed patients (HIV, renal transplant). It can cause renal parenchymal disease or obstructive uropathy. The prostate has been a rare site of infection. Renal aspergillosis or pseudotumor has been reported in patients with AIDS. Striae can be negative, but aspiration and cytology can demonstrate typical septated hyphal. Therapy is systemic amphotericin B at least 3 mg/kg, or voriconazole. Amphotericin B in suspension is given through a central venous catheter. Amphotericin B in suspension has been the most successful approach to therapy. Through a retrograde ureteral catheter instillation of a solution of amphotericin B in sterile water is infused at 40 ml/h. Shade the solution to limit degradation. Monitor pressure with a pop-off mechanism at 25 cm water. (See also Section II: Fungal Infections, Genitourinary.)

REFERENCE

ASPERMINA

DESCRIPTION
A condition of no ejaculate, which should be differentiated from aspermia, where an ejaculate is present but the sperm are absent from the fluid. (See also Section II: Infertility, Urologic Considerations) and “Ejaculatory Disturbances (Delay, Decreased, or Absent).” Section II: “Semen Analysis, Technique, and Normal Values.” Section II: “Semen Analysis, Abnormal Findings, and Terminology.”

CAUSES
• Complete bilateral obstruction of ejaculatory duct
• Congenital anomalies, imperforate anus, and other congenital anomalies
• Medication (Hypogonadal, α-blockers, methyldopa, imipramine)
• Radical prostatectomy (RP)
• Retrograde ejaculation; failure of seminal emission

REFERENCE
plastic sperm injection by testicular sperm in pa-
bients with aspermia or azoospermia after cancer 

ASSISTED REPRODUCTIVE TECHNOLOGY (ART)

DESCRIPTION
ART includes all fertility treatments in which both eggs and sperm are handled. Although the Centers for Disease Control and Prevention does not include treatments in which only sperm are handled, there are various methods of sperm retrieval as defined below:

• Percutaneous epididymal sperm aspiration (PESA): Aspiration of sperm from epididymal percutaneously
• Microsurgical epididymal sperm aspiration (MESA): Done by open surgery
• Testicular sperm aspiration (TESA): Done percutaneously
• Testicular sperm extraction (TESE): Done through open biopsy of testicular tissue

• Intratissue insemination (II) or Artificial insemination (AI). Also not ART by strict definition; however these are methods for fertility performed during ovulation by inserting a catheter into the cervix or as injecting concentrated sperm into the uterus, thereby bypassing the cervical mucus barrier.

The following are classical methods of ART:

• Gamete intraturbulap transfer (GIFT): Oocytes and sperm are retrieved, the semen is concentrated, then both are placed into the fallopian tube by laparoscopy.
• In vitro fertilization (IVF): Fertilization by either including sperm with oocytes or by inserting a single live sperm into an oocyte with a micropipette called intracytoplasmic sperm injection (ICSI). The resultant embryo is transplanted to the uterus or fallopian tube with a catheter through the cervix.

In 2017, after IVF of an egg, the resultant embryo is placed into the fallopian tube laparoscopically, instead of through the cervix.

REFERENCE

ASTHENOSPERMIA

DESCRIPTION
A general term for defects in sperm movement, usually a decrease in sperm motility to <30–40% of normal. It can be detected on semen analysis and can be a cause of male factor infertility. (See also Section II: Infertility, Urologic Considerations, Section II: “Semen Analysis, Abnormal Findings, and Terminology.”)

CAUSES
• Antibody antibodies
• Hypogonadotropic state
• Hypogonadism
• Immotile cilia (Kartagener syndrome and immotile cilia syndrome)
• Infection
ATHLETIC HEMATURIA

- Partial ejaculatory duct obstruction (EDO)
- Varicocele (most common surgically correctable abnormality)

TREATMENT

- Aimed at offending agent (ie, antibiotics for infection, sperm washing for antibodies, varicocelectomy)
- Has been noted in vitamins C and E and other low-radical scavengers

REFERENCE

ATHLETIC HEMATURIA

DESCRIPTION

Hematoma, microscopic, or gross, can be noted in athletes engaged in high-intensity or long-duration exercise. Usually benign in course. Repeated episodes of hematuria may cause anemia in some athletes. Theorized causes include stress from hematosis, renal ischemia, release of a hemolyzing factor, direct trauma to bladder or kidney, dehydration, myoglobinuria, increased circulating, and HOBs. Treatment includes adherence to sensible training guidelines and hydration.

SYNONYMS

- Sport-related hematuria
- Exercise-induced hematuria

REFERENCE

ATOPIC DERMATITIS (ECZEMA), UROLOGIC CONSIDERATIONS

DESCRIPTION

Also called eczema, disseminated nervous, atopic eczema, or “itchy-pruritic” skin disease. This chronic pruritic inflammatory condition affects characteristic sites. In adults, the genitalia is a common site. Patients present with itching, excoriations, edema, erythema, and scaling. As the disease progresses, the skin undergoes lichenification (thickening). The cause is unknown, but there is a familial association with this and other atopic disorders (allergic rhinitis, asthma).

TREATMENT

Topical corticosteroids as triamcinolone 0.1% BID nighttime sedation with antihistamines or other agent. Treat stress and remove irritants (soaps, cleansers, fabric made of wool or nylon).

REFERENCE

ATTENTIVE DIGITAL RECTAL EXAM

DESCRIPTION

Utilized to obtain prostate specific antigen in urine to identify DNA, RNA, protein, and metabolite based biomarkers for the detection of prostate cancer. Clinical studies have identified PCA3 and TMPRSS2:ERG fusion transcripts as promising RNA markers for cancer detection and possibly prognosis. A “light prostate massage” should be performed, including firm pressure to depress the gland by 1 cm. A total of 3 strokes per lobe should be performed from base to apex and from lateral to median line. (See Attentive digital rectal exam [DRE] image.)

REFERENCE

ATYPICAL ADEMOMATOUS HYPERPLASIA OF THE PROSTATE (ADENOSIS)

DESCRIPTION

Some lesions can be confused with low-grade prostate cancer on small-needle biopsy samples. The differential diagnosis of these confusing pseudoneoplastic lesions includes atypical adenomatous hyperplasia of the prostate (AAH), sclerosing adenosis, postatrophic hyperplasia, basal cell hyperplasia, and others that must be differentiated from low-grade prostate carcinoma. Histologically, AAH is a crowded focus of small glands. It has not yet been definitively associated with an increased risk of prostate cancer. AAH is no longer considered a premalignant lesion but rather a benign small glandular process of the transition zone that simulates adenocarcinoma. It is recommended to stain for α1B and α1D, which detect basal cell-specific α1. If basal cell staining is present, this helps to rule out carcinoma. Although the biologic significance of AAH is uncertain, its tight microscopic appearance and immunophenotype allow it to be distinguished from carcinoma in most cases. The lesion appears to be distinct from atypical small acinar proliferation (ASAP), which appears to be more associated with prostate cancer (in AAH, reactivity is not usually indicated). See also Section II: “Atypical Small Acinar Hyperplasia, Prostate (ASAP);” Section III: “Postatrophic hyperplasia of the Prostate Gland.”

SYNONYM

- Small gland hyperplasia
- Atypical adenosis
- Atypical small acinar hyperplasia

REFERENCE

ATYPICAL SMALL ACINAR PROLIFERATION, PROSTATE (ASAP)

DESCRIPTION

Prostate needle biopsies occasionally contain cells identified as ASAP that are suspicious for but not diagnostic of malignancy. About 2% of contemporary prostate needle biopsy specimens contain collections of small acini that are suspicious for cancer but that fall below the diagnostic threshold and are often reported as “ASAP suspicious for but not diagnostic of malignancy.” Prostate cancer has been identified in specimens from subsequent biopsies in up to 60% of cases of ASAP indicating this finding is a significant predictor of cancer. Identification of ASAP (with or without high-grade PIN) warrants repeat biopsy for confirm of subsequent invasive prostate carcinoma. (See also Section I: “Prostatic Intratubular Neoplasia;” Section II: “Atypical Adenomatous Hyperplasia and Postatrophic Hyperplasia of the Prostata.”)

REFERENCE

AUA (AMERICAN UROLOGIC ASSOCIATION) SYMPTOM INDEX FOR BPH

DESCRIPTION

Also called the BPH symptom index, and the AUA symptom score or AUA-5, this standardized instrument assesses the degree of lower urinary tract symptoms (LUTS) due to BPH in men, as well as guides response to treatment. Originally developed by the AUA, it is now widely used. (See Section VII: Reference tables: AUA Symptom/International Prostate Symptom Score [IPSS].) The AUA Index consists of 7 questions that assess emptying, frequency, intermittency, urgency, weak streams, and straining, with each graded on a scale of 0–5. Scores can range from 0–35. The index currently categorizes symptoms as:

- Mild (score ≤7)
- Moderate (score 8–19)
- Severe (score ≥20)

The International Prostate Symptom Score (IPSS) is identical to the AUA index, except that it adds a single question to assess the quality of life based on the patient’s perception of the problem. This is scored from 0 (“improved”) to 6 (“worse”). It is suggested that patients with mild symptoms (IPSS ≤7) and patients with moderate or severe symptoms (IPSS >7) who are not bothered by their symptoms (ie, symptoms do not interfere with daily activities) should be managed by watchful waiting, although a wide range of patients with bothersome moderate to severe symptoms prefer this strategy as well. Today, most patients undergo medical management (ie, blockers with or without 5α-reductase inhibitors or 5α-reductase alone prior to any surgical intervention). Surgical options include TURP, transurethral incision of the prostate, open prostatectomy, or minimally invasive therapies (such as transurethral microwave thermotherapy, transurethral needle ablation, and laser-induced photodynamic therapy). (See Section II: “International Prostate Symptom Score (IPSS);” Section VII: “AUA Symptom Index for BPH.”)

REFERENCE

AZOOSPERMIA

DESCRIPTION

The absence of viable sperm on semen analysis and a documented cause of male factor infertility. Azoospermia can be obstructive or nonobstructive. When 1st noted, the sample should be centrifuged and the pellet examined for the presence of sperm. If present, a workup for oligospermia should be performed. A postejaculate urine analysis should be obtained to rule out retrograde ejaculation (ie, the urine contains significant numbers of sperm).
10–15 HPF). If absent, a physical exam for the presence of vasa deferentia and hormone studies are indicated. Treatment is based on the underlying cause. (See also Section I: “Infertility, Urologic Considerations.”) Section II: “Semen Analysis, Abnormal Findings, and Terminology.”

CAUSES
- Congenital absence of vasa deferentia
- Ductal obstruction
- Germ cell failure
- Gonadotoxicity
- Hypoplasmatropic hypogonadism
- Idiopathic
- Testicular failure (Klinefelter syndrome)

REFERENCE

BACK PAIN, UROLOGIC CONSIDERATIONS
DESCRIPTION The differential diagnosis of back pain includes several potential urologic etiologies:
- Cauda equina syndrome is a surgical emergency. Common findings are bladder dysfunction (especially urinary retention) and saddle anesthesia, in addition to sciatica and weakness.
- Endocrine: Adrenal hyperplasia or infarction
- Gynecologic: Neoplasm of uterus or ovary, endometriosis
- Infection: Tuberculosis, osteomyelitis, subarachnoid or spinal abscess
- Medication: Tadalafil—incidence of back pain and/or arthralgia
- Neoplastic: Myeloma, Hodgkin disease, carcinoma of breast, prostate, lung
- Neurologic: Trauma: Injury to bone, joint, internal organs, or ligament
- Orthopedic: Osteomyelitis, fractures
- Psychogenic: Travel anxiety
- Spinal: Intraspinal tumors
- Spondylosis
- Vascular: Vascular thrombosis or embolus

REFERENCES

BALKAN KNEPHROPATHY
DESCRIPTION An immunologic nephropathy endemic to the Balkan Republics of Yugoslavia, Bulgaria, and Romania, and that afflicts mainly the middle-aged rural populations. It is slowly progressive, and may eventually lead to ESRD. Anemia, polyclonality, and hypertransfusion can be seen. Renal biopsy has no specific markers for the disease. Balkan endemic nephropathy is caused by eating bread that is contaminated with a toxin called aristolochic acid, which comes from a plant called Aristolochia. Balkan endemic nephropathy can occur in multiple family members, but it is not an inherited condition. A strong association with increased incidence of upper tract transitional cell carcinoma (TCC) has been documented, although bladder TCC incidence is normal. Treatment involves aggressive surveillance for TCC and renal replacement therapy, as necessary. (See also Section II: “Aristolochic acid” [Tang et al].)

REFERENCE

BANFF CLASSIFICATION, TRANSPLANT REJECTION
DESCRIPTION A classification method developed in 1993 for standardization of criteria in the histologic diagnosis of renal allograft rejection. The Banff classification characterizes renal biopsy findings into a scheme that outlines possible clinical approaches to manage the rejection. (See also Section I: “Transplant Rejection, Renal.”)

REFERENCE

BARCET-REDMAN HYPOSPADIAS REPAIR
DESCRIPTION In a modification of the Mathieu procedure, this repair mobilizes the posterior urethral plate and splits the glans in addition to the penile flap. The full thickness penile and urethral plate grafts are tailored together and laid to rest in the new urethral groove.

REFERENCE

BARIATRIC SURGERY, UROLOGIC CONSIDERATIONS
DESCRIPTION Bariatric surgery, the 1st bariatric procedure, produced severe hyperkalemia secondary to tubular atrophy. Modern bariatric surgery utilizes gastric restrictive procedures and sometimes bypass of variable amounts of small intestine, such as Roux-en-Y gastric bypass and biliopancreatic diversion. Modern bariatric surgery is associated with less malabsorption compared to jejunoileal bypass; however, contemporary bariatric bypass patients continue to have hyperkalemia, hypertriglyceridemia, and lower urine volumes, which result in an increased risk of calculus formation.

REFERENCE
BASHFUL BLADDER (PARURESSIS, SHY BLADDER SYNDROME, “PEE-SHY”)

DESCRIPTION

This is the inability to urinate with others present, such as in a public restroom. It is a relatively common disorder but little is understood about the phobia. According to DSM-III TR, this disorder is classified as social phobia.

REFERENCE

BFG REFRACTORY TRANSITIONAL CELL CARCINOMA (TCC)

DESCRIPTION

TCC that recur after treatment with intravesical BCG treatment. Failure of initial intravesical therapy may be managed by further intravesical therapy or cystectomy. With more aggressive therapy indicated for high-risk patients having superficial invasion (T1), high-grade lesions or concomitant carcinoma in situ (CIS). Patients with high-risk features who fail a 2nd course of BCG have a very high-risk of progression to muscle-invasive TCC. In addition, relapses after >2 courses of BCG appear to be associated with poor outcomes, despite subsequent aggressive therapy. Several different salvage therapies, including intravesical interferon alone or in combination with BCG, valrubicin, mitomycin C, gemcitabine, and other chemotherapeutic agents, as well as photodynamic therapy, have been described for BCG failures. salvage therapies have poor response rates; however, and radical cystectomy remains the “gold standard” for the salvage of failed intravesical therapy in high-risk patients. (See Also Section II: “Bladder Cancer, General.”)

REFERENCE

BCL-2, UROLOGIC CONSIDERATIONS

DESCRIPTION

The protein product of the gene bcl-2-2 acts as an apoptotic blocking agent. It appears to be required for normal morphogenesis of the kidney, and may be unimportant as a prognostic factor in RCC. It is seen in higher levels in prostatic intraductal hyperplasia but is variable in prostate cancer. Levels increase during XRT. Expression is increased in high-grade bladder tumors.

REFERENCE

BECKWITH–WIEDEMANN SYNDROME

DESCRIPTION

This condition is characterized by macrosomia, abdominal wall defects, adrenal cytomegaly, and neonatal hypoglycemia. Other characteristic features include gigantism, variable creases and pits, facial rashes, and prominent eyes with infraorbital recessions. Neonatal hypoglycemia is frequent, of which Wilms tumors, adrenal cortical carcinoma, and hepatoblastoma are most common. Mental retardation is not associated. Most cases are sporadic, but a genetic cause related to mutation or deletion of imprinted genes within the chromosome 15p15.5 region. The mode of inheritance of BWS is complex. Focalis patterns include: autosomal dominant inheritance with variable expressivity, contiguous gene duplication at 15p11, and genomic imprinting resulting from a defective or absent copy of the maternally derived gene. Several lines of evidence support that BWS may be causally associated with right overexpression of the paternally imprinted IGF2 gene. Some suggest a slightly increased risk in babies born by assisted reproduction. Close follow-up early in life is recommended for tumor surveillance as 1 of the most serious findings is the increased risk of neoplasia. In 1 series the majority of tumors were Wilms tumors (67%), followed by hepatoblastomas (11%), rhabdomyosarcomas (5%), and neuroblastomas (4%).

SYNONYM

EMCN syndrome (exomphalos, macrosomia, and gigantism)

REFERENCES

REFERENCES

BEER NEPHROURETERECTOMY

DESCRIPTION

Refers to a retroperitoneal 2-incision approach to a nephroureterectomy through a flank and a separate Gibson or a midline Czerny incision.

REFERENCE

BELLINI DUCT CARCINOMA (COLLECTING DUCT CARCINOMA)

DESCRIPTION

A variant of RCC in which the cell of origin is the collecting duct. Very few cases are reported in literature. Immunohistochemically, the lesion stains with high–molecular-weight keratin and lectin. Histologically, cells demonstrate intracytoplasmic mucinoic material, which is not seen in RCC. Radial nephrectomy for localized disease is the treatment of choice. Chemotherapy is used (interferon–ω-based) for metastatic disease. (See also Section I: “Renal Mass.”) (Image 9-4)

REFERENCE

BEER POTOMANIA

DESCRIPTION

A hypo-osmolality syndrome of beer drinkers, usually with hypoglycemia. Patients with beer potomania have a history of significant beer drinking, often lifelong, in conjunction with a poor diet. This may occur because beer has very little sodium and no protein, and the condition is potentially augmented by the possibility of inappropriate antidiuretic hormone (ADH) secretion.

TREATMENT

Fluid restriction, (CI) monitoring, and serial serum sodium levels, with slow correction of hypoglycemia.

REFERENCE

BEHÇET DISEASE

DESCRIPTION

This is a multisystem vasculitis that is most active during youth; adulthood syndrome characterized by oral and genital ulcers (vulvar and perianal), uveitis, vascular involvement (venous thrombosis, vasculitis), and normocytic normochromic anemia. Lesions on the genitalia are hyperemic and can be painful. Other genital ulcers, such as syphilis, herpes, and chancroid, must be ruled out. Oral ulcers are treated with local moisture-retaining dressings, topical anesthetics, and corticosteroids. Rebutepine is used to treat oropharyngeal ulcers. For severe mucocutaneous lesions, immunosuppressive systemic agents (steroids, azathioprine, penicillin-G, dapsone, interferon-α, colchicine, and thalidomide) have demonstrated benefits.

REFERENCE

BRENNER TUMOR

DESCRIPTION

A renal neoplasm initially described by Dr. Elmer Belt, who described his technique for performing radical perineal prostatectomy in 1939. Dr. Belt described a new approach to the prostate through the perineum between the longitudinal fibers of the rectum and the circular fibers of the external anal sphincter. This approach dramatically decreased blood loss. However, Dr. Belt also recommended leaving behind the apex of the prostate to achieve better urinary control, and opening the anterior layer of the Denonvillier fascia during the dissection.

REFERENCE

BENCHKROU N ILEAL VALVE
DESCRIPTION
A hydraulic valve is used as the continence mechanism in ileal or ileocecal reservoirs. As the reservoir fills, increased pressure occurs in the valve, which is created by imagining an ileal segment that then serves as the effenter continent limb.

REFERENCE

BERGER DISEASE (LG NPHROPATHY)
DESCRIPTION
Sometimes referred to as “hyaluronic immunoglobulin A nephropathy,” this condition was 1st described by Berger and Hinglas in 1966. As the most common primary glomerulonephritis, it exhibits a wide variation in manifestation, ranging from a benign, indolent course to rapidly progressive renal failure. Commonly presents with hematuria, proteinuria, and abnormal urine sediment. Diagnosed by renal biopsy demonstrating LG deposits in the mesangium on immunofluorescence staining.

TREATMENT
• Recent promise seen in corticosteroids, fish oil, and ACE inhibitors
• Renal transplant for cases of renal failure

REFERENCE
Sometimes referred to as

BERGERMAN SIGN
DESCRIPTION
In ultrasonic radiography, the Bergman sign occurs when the ureter is dilated immediately below a neoplasm, rather than collapsed, immediately below a neoplasm, rather than collapsed, as shown in a chalice shape. Retrograde pyelography demonstrates the chalice appearance; a ureteral catheter tends to curl in this segment. The Bergman sign is pathognomonic for neoplasm.

REFERENCE

β-HCG (HUMAN CHORIONIC GONADOTROPIN)
DESCRIPTION
β-HCG is a polypeptide of a molecular weight of 38,000 and a half-life of 2 days. It is produced normally by the syncytiotrophoblast cells in pregnancy. β-HCG is composed of 2 subunits, α and β. The α subunit is identical to a subunit of LH. Urologic uses include staging and follow-up of testicular cancer (elevated in 100% of choriocarcinoma, 7% of seminoma, 60% of embryonal carcinomas). Has been produced by urethral tumors and secreting polynymipharynx. Therapeutically can be given exogenously to stimulate low-grade cells in secondary hypogonadism and facilitate descent of undescended testicles when administered over several weeks. Typical regimen is 500–2,500 U IM 2 times a week for 4 wk. The HCG test is used to diagnose anorexia in undescended testicles; a failure to increase testosterone after administration suggests anorchia. (See also Section I: “Tests, Carcin, General”;

REFERENCE

BIOFEEDBACK, UROLOGIC CONSIDERATIONS
DESCRIPTION
Any method of training the body while receiving feedback on the specific function being trained. Biofeedback ranges from “low tech” (eg, vaginal cones for incontinence) to sophisticated electronic systems (utilizing EMG or pressure probes). Biofeedback is applied in urology for improvement of urinary incontinence, generally by strengthening pelvic floor muscles, and for treatment of dysfunctional voiding. Biofeedback has also been used to teach patients to stop uncontrolled detrusor contractions, teach relaxation of the pelvic floor, and promote normal voiding in children.

REFERENCE

BIOFILM, UROLOGIC CONSIDERATIONS
DESCRIPTION
When microorganisms adhere to the surface of an urologic device (catheter, ureteral stent, implant) and create a matrix of extracellular polymeric substance, Biofilms provide resistance to antimicrobial agents by preventing penetration through the film and thereby limiting access to bacteria. Bacteria protected by a biofilm can also have low expression of antimicrobial binding proteins and activation of intrinsic resistance genes. Biofilm bacteria can typically withstand 1,000–1,500× the concentration of antimicrobial agents utilized to kill nonfilm bacteria. Numerous strategies to avoid biofilm formation are currently being researched. Options include modifying biomaterial surface properties,
DESCRIPTION

Bites to the penis can result in significant injury. Of animal bites, the most common is the dog bite. These can be potentially severe, with deep tissue destruction. In the cases of animal bites, patients tend to present early, and usually the wound can be closed after copious irrigation and any necessary debridement is performed. Broad-spectrum antibiotics should be administered, and wound closure is generally avoided. (See also Section I: “Penis, Trauma.”)

REFERENCES

BIOTHESIOMETRY, PENILE

DESCRIPTION

A simple, inexpensive method of testing the sensory threshold when evaluating neurogenic causes of impotence. It is performed by measuring sensory thresholds, usually in at least 3 different areas of the body, such as the medial malleolus, fingertips, and glans penis. Probably not as accurate and reproducible as other forms of neurologic testing, such as vibral-evoked potentials, pudendal-evoked potentials, and BCR latency. (See also Section I: “Erectile Dysfunction/Impotence, General.”)

REFERENCE

BIRT-HOGG-DUBÉ SYNDROME

DESCRIPTION

Birt-Hogg-Dubé (BHD) syndrome is a rare, autosomal dominant disorder 1st described in 1977. It is caused by germline mutations in the BHD (FH1) gene that lies within the chromosomal band 17p11.2 and encodes for a tumor suppressor protein, folliculin. Folliculin is highly expressed in a variety of tissues, including the skin, kidney, and lung (stromal cells and type I pneumocytes). BHD syndrome is the cutaneous triad of fibrofolliculomas (hamartoma of the hair follicle), trichodiscomas, skin tags, and a propensity for renal tumors. The renal tumors are often chromophobe RCC, oncocytoma, or hybrid of these tumors. However, many will develop clear cell tumors as well. These tumors are more likely to be multiple and bilateral. (See also Section I: “Renal Cell Carcinoma, General.”)

REFERENCE

BITES TO PENIS, ANIMAL, AND HUMAN

DESCRIPTION

Bites to the penis can result in significant injury. Of animal bites, the most common is the dog bite. These can be potentially severe, with deep tissue destruction. In the cases of animal bites, patients tend to present early, and usually the wound can be closed after copious irrigation and any necessary debridement is performed. Broad-spectrum antibiotics should be administered, and wound closure is generally avoided. (See also Section I: “Penis, Trauma.”)

REFERENCES

BLACK-WATER FEVER

DESCRIPTION

Black-water fever is a clinical entity characterized by acute intraocular hemolysis, classically occurring after the introduction of quinine for treatment of malaria. It is a rare but serious condition, in which hemolytic and anemia produce characteristically dark-colored urine. The condition has become rare since 1950, when quinine was replaced by chloroquine. Currently, it has reemerged from the development of resistance to chloroquine. Treatment of black-water fever is supportive, including stopping the offending drug, blood transfusion for severe anemia, and a short course of steroids. (See also Section I: “Malaria, Considerations.”)

REFERENCE

BLADDER AGNESIS

DESCRIPTION

Rare and usually virutal congenital abnormality that has been reported in >20 living patients. Associated abnormalities include renal agenesis, urotelial uterum, crossed fused renal ectopia, malrotation of the gut, colon duplication, anal atresia, imperforated anal canal, and bicornuate uterus. It is caused by a unsgenital virus abnormality during week 5–7 of development.

TREATMENT

• Separation of urinary and fecal stream
• Other reconstructive surgery as appropriate

REFERENCES

BLADDER AUGMENTATION

DESCRIPTION

Bladder segments are most commonly used to improve bladder capacity and manage poorly compliant bladders. The goal is to protect upper urinary tract drainage and maintain renal function. Augmentation cystoplasty is utilized mainly in patients with disorders of the neuologic system (e.g., spinal cord injury [SCI], multiple sclerosis [MS], myelodysplasia). Modifications with bladder neck reconstruction and/or addition of continent channels (interstomal or Monti channel) can be utilized to facilitate both continence and ease in drainage. Complications associated with bladder augmentation include failure to adequately improve bladder capacity, metabolic disturbances, mucous plugging, urinary tract infections, bladder calculi, vesicourethral reflux, bladder perforation, and malignancy (usually adenocarcinoma most commonly located at the region of the anastomosis).

REFERENCE

BLADDER CANCER, INTRAVESICAL AGENTS

DESCRIPTION

Either immunotherapy agents, such as BCG, or chemotherapy agents, such as mitomycin C, are instilled directly into the bladder for the treatment of either carcinoma in situ or high-grade superficial urothelial carcinoma. Adjunct intravesical chemotherapy regimens have been shown to decrease recurrence rates but no clear improvement in overall progression has been demonstrated. Patients who fail intravesical therapy should be evaluated for extirpative treatment. (See also Section I: “Bladder Cancer, General.” “Bladder Cancer, Nephrometic Invasive Bladder Cancer [Ta, T1],” and “Bladder Cancer, Urthelial, Superficial Carcinoma in Situ [T1 NMIBC].”

REFERENCES

656

**BLADDER EARS**

**DESCRIPTION** Primary choriocarcinoma of the bladder is exceedingly rare. Only 7 cases are described in the literature. Most cases present with hematuria and may also have gynecomastia. Metastasis and juxtacystic invasion were seen in the majority of reported cases. A full metastatic workup including social exam and ultrasonogram are mandatory. 3 of the 7 cases were treated with resection and then chemotherapy, and all showed good response (1 patient died of pulmonary embolus during therapy), the other 4 patients died of the disease. (See also Section 1 “Bladder Cancer, General”).

**BLADDER CONTRACTILITY INDEX (BCI)**

**DESCRIPTION** A urodynamic variable. BCI = \( P_{\text{det}}/Q_{\text{max}} < 100 \) defines low detrusor pressure. \( P_{\text{det}} = 10Q_{\text{max}}/1000 \) is the maximum detrusor pressure at maximum flow rate and \( P_{\text{det}}/Q_{\text{max}} \) is the detrusor pressure at maximum flow. Poor detrusor contractility is defined as BCI < 100, normal contractility is BCI between 100 and 150, and strong bladder contractility is BCI > 150.

**BLADDER DIVERTICULUM**

**DESCRIPTION** A bladder diverticulum is a herniation of the urothelial mucosa through the detrusor muscle. Bladder diverticula may be congenital or acquired. Most acquired diverticula are associated with long-standing bladder outlet obstruction (high intravesical pressures) and are most commonly seen in elderly men with benign prostatic hyperplasia or other forms of bladder outlet resistance; it is rare in women. The condition usually evolves from bladder wall trabeculation, to cellule, and finally a diverticulum, typically located on the lateral wall and away from the dome. Since the acquired diverticula have no muscle wall components, they do not empty well and cause urinary stasis with increased risk of infection, stones, and uterine prolapse (urovaginal hernia). The lack of a muscular wall makes urethral carcinoma more likely to extend outside the bladder’s cavity. Congenital bladder diverticula are uncommon and occur almost exclusively in boys. When next to the ureteral orifice (low diverticula), this can result in vesicoureteric reflux on that side. Treatment usually involves correction of the outlet obstruction to reduce high-pressure voiding. Diverticulectomy (open or laparoscopic) can be performed for recurrent infection or bladder calculus. Treatment for cancers within diverticula may include transurethral resection (can be complicated by narrow orifices and thin diverticular wall), laser ablation, diverticulectomy, partial cystectomy, and radical cystectomy with or without intravesical therapy (Image 4).

**BLADDER EARS**

**DESCRIPTION**Transient bladder outpouchings into the trigonal orifice of male infants <6 mo old. This close association of the bladder with the internal ring resolves spontaneously. Inguinal hernorrhaphy in male infants can result in significant bladder damage if bladder ears are present. The condition is differentiated from bladder diverticula by absence of a definable neck.

**REFERENCE**
**BLADDER FILLING DEFECTS**

**DESCRIPTION**
Filling defect on a contrast study of the urinary bladder (cytography) may be the result of:
- Air: Artifactual, postinstrumentation, wessoniometric fistula
- Benign tumor: Prostatic enlargement, inverted papilloma, endometriosis
- Blood clot
- Calculus
- Congenital: Ureterocele
- Extravasitic compression by pelvic organ or mass, pelvic lipomatosis
- Fungal ball (Bazex)
- Infective, inflammatory: Inflammatory edema
- Instruments (catheter), foreign body
- Malignant tumor: Bladder and prostate malignancies, tumors invading urinary bladder from contiguous organs (e.g. uterine, colon)
- Radiologic artifact: Fold in nondistended bladder

See also Section I: “Bladder calculus (neural calculus)” and Section II: “Bladder Mass, Differential Diagnosis.” (Image E)

**SYNONYM**
- Bladder cystocoele

**REFERENCE**

**BLADDER HYPOPLASIA**

**DESCRIPTION**
Lack of urinary bladder development, leading to inadequate function and storage capacity. Hypoplasia is caused either by failure of production or storage of urine, or from complete obliterates of the bladder. Causes include: congenital: renal dysplasia, tuberculosis, bilateral renal agenesis, severe renal dysplasia, and bilateral ureteral ectopia. Bladder reconstruction with bowel-segments can be attempted.

**REFERENCE**

**BLADDER, LYMPHOMA**

**DESCRIPTION**
In lymphoma, involvement of the bladder is usually secondary to systemic disease. Primary lymphoma of the bladder is rare, and carries an excellent prognosis. Most patients are female in the 7th–8th decades. Patients typically present with gross hematuria. The tumors can be single or multiple, sessile or papillary. Most common types are large-cell and small-cell lymphocytic lymphoma and further classified as MAC (medial corticomedullary 8-cell lymphoma). Lymphomas thought to result from chronic inflammation. Many patients in recent series have chronic cystitis. Radiotherapy has been the treatment of choice for localized lymphoma; otherwise, systemic therapy is undertaken if the bladder is not the primary site.

**REFERENCE**

**BLADDER, LEIOMYOMA**

**DESCRIPTION**
A benign spindle cell lesion in the bladder wall. Although these tumors are very rare, they are the most common bladder mesenchymal tumor. The tumors can be single or multiple, sessile or papillary. Most common types are large-cell leiomyosarcoma, myxoid sarcomatoid carcinoma, and myxoid leiomyosarcoma. Resection is the treatment.

**REFERENCE**

**BLADDER, INFLAMMATORY PSEUDOTUMOR**

**DESCRIPTION**
A benign spindle cell lesion in patients who have not had surgery (as opposed to postoperative spindle cell nodules). Most patients are from 20–50 yo and present with gross hematuria. The lesion is nodular or pedunculated, but some may be sessile and invade the muscularis propria. This is a benign lesion, but it must be differentiated from myoid sarcomatoid carcinoma and mesothelial lesions. Resection is the treatment.

**REFERENCE**

**BLADDER, LEIOMYOSARCOMA**

**DESCRIPTION**
Though very rare, it is the most common mesenchymal tumor of the bladder, constituting 0.1% of all bladder neoplasms. Usually incidentally discovered, though if large or pedunculated may present with bladder outlet obstruction. Seen more commonly in females. Generally heterogeneous and smoothly marginated on ultrasound and CT. MRI better and shows the submucosal origin, usually has low T2 and intermediate T1 signal.

**TREATMENT**
- Partial cystectomy can be required for large lesions or primary and secondary involvement by leukemia has been reported.

**REFERENCE**

**BLADDER, RADIATION CUSTODIAL TUMOR**

**DESCRIPTION**
Benign tumor: Prostatic enlargement, inverted papilloma, endometriosis

**REFERENCE**

**BLADDER, HYPOPLASIA**

**DESCRIPTION**
Most are found in the inguinal or femoral region and are often associated with bladder outlet obstruction in men. It is estimated that up to 4% of all inguinal hernias can contain some degree of bladder herniation. Rarely, massive herniation may be found, with significant portions on the bladder and distal ureter descending into the contents; bladder obstruction and distraction has been reported. In women, herniation of the bladder into the anterior vaginal wall is technically a rectocoele. Treatment is repair of inguinal hernia, with reduction of bladder herniation. Bladder outlet obstruction should be identified and treated in males as this may contribute to the original herniation and subsequent recurrences.

**REFERENCE**
**BLADDER SARCOMA (LEIOMYOSARCOMA/RHABDOMYOSARCOMA)**

**BLADDER NECK CONTRACTURE**

**DESCRIPTION**
Scarred and stenotic of the bladder neck is most commonly as a postoperative complication of transurethral resection of the prostate or radical prostatectomy at the site of vesical urethral anastomosis. Bladder neck contracture may lead to decreased urinary flow, high-pressure voiding, urinary retention, urinary tract infections, and incontinence. Factors associated with this complication include urinary leak at the anastomosis, poor muscle approximation, suture retraction, ischemia, or foreign bodies such as surgical clips. Postoperative radiation may contribute. Radiation monotherapy can cause contracture with the presentation from 12–36 mo after completion. Management consists of dilution, endoscopic incision (saw, cold cut, electrocautery) or resection, and, in severe cases, open repair utilizing a Y-V plasty. Occasionally, intermittent self-catheterization may be needed to maintain patency.

**REFERENCE**

**BLADDER NECK HYPERTROPHY**

**DESCRIPTION**
Hypertrophy of the bladder neck is non-inflammatory bladder neck hypertrophy. It may have a role in clinical practice in the future. It consists of 8 questions divided into broad areas: Urge to urinate, urinary frequency, and bladder pain and pressure. For the scoring, a single score is created by summing all 8 items to create a total score ranging from 0–38.

**REFERENCE**

**BLADDER, NEUROFIBROMA**

**DESCRIPTION**
A rare benign tumor of the nerve sheath from overgrowth of Schwann cells, these lesions originate in the bladder from ganglia in the wall. They can present in childhood as obstruction or voiding symptoms. Malignant degeneration is rare. The condition is spread or related to neurofibromatosis. Conservative resection, as needed, is the usual treatment. With severe obstruction or intolerable symptoms, cystectomy may be needed.

**REFERENCE**

**BLADDER OUTLET OBSTRUCTION INDEX (BOOI)**

**DESCRIPTION**
Based on the International Continence Society (ICS) nomogram for identifying bladder outlet obstruction during urodynamic evaluation. The ICS nomogram categorizes patients with LUTS into obstructed, equivocal (or slightly obstructed) or unaffected based on the maximum detrusor pressure during voiding versus the maximum flow rate.

**REFERENCE**

**BLADDER PAIN/INTERSTITIAL CYSTITS SYMPTOM SCORE (BPIC-SS)**

**DESCRIPTION**
BPIC-SS is a questionnaire to select bladder pain syndrome/intestinal cystitis patients for clinical trials. It may have a role in clinical practice in the future. It consists of 8 questions divided into broad areas: Urge to urinate, urinary frequency, and bladder pain and pressure. For the scoring, a single score is created by summing all 8 items to create a total score ranging from 0–38.

**Bladder Pain/Intestinal Cystitis Symptom Score (BPIC-SS)**

**Concept** Item

Urine to urinate: In the past 7 days, how often did you still feel the need to urinate just after you urinated? In the past 7 days, how often did you urinate after you urinated, how often was it because of pain in your bladder?

Urinary frequency: In the past 7 days, how often were you by having to get up during the night to urinate? In the past 7 days, how often were you having to get up during the day to urinate?

Bladder pain and pressure: In the past 7 days, how often do you have a feeling of pressure in your bladder? In the past 7 days, how often did you have pain in your bladder? Select the number that describes your worst bladder pain in the past 7 days.

**REFERENCE**

**BLADDER, PARAGANGLIOMA**

**DESCRIPTION**
Similar to pheochromocytoma in other areas of body. 10% are malignant. They are thought to arise from paraganglion cells in bladder, usually around the trigone. Most are hormonally active and can present with hypertension during bladder filling and firing. Can appear as a submucosal tumor on cystoscopy. Late metastasis can occur, so long-term follow-up is warranted.

**TREATMENT**
• Partial cystectomy is the treatment of choice
• TUR may cause a hypertensive crisis

**REFERENCE**

**BLADDER, PHEOCHROMOCYTOMA**

BLADDER SMALL CELL CARCINOMA (OAT CELL, SIGNET RING)

For pediatric rhabdomyosarcoma, a multimodal approach utilizing surgery, radiation, and chemotherapy is employed, with improving rates of bladder preservation and improving prognosis. Metastatic disease treatment remains controversial with resection, radiation, and chemotherapy with single-agent chemotherapy in refractory disease. See also Section II: “Bladder Cancer, General.”

REFERENCES

BLADDER SMALL CELL CARCINOMA (OAT CELL, SIGNET RING)

DESCRIPTION
Small cell carcinoma or oat cell carcinoma is an aggressive malignancy derived from either neuroendocrine or pluripotent cells. This tumor most commonly arises in the lung, but may occur in multiple locations including the bladder and less frequently the prostate. Neuroendocrine tumor of the bladder is rare, with ∼283 cases reported in the literature. It can be seen alone or in conjunction with other tumor types, most frequently TCC. Small cell carcinoma of the bladder presents as any other bladder tumor, most frequently with hematuria. The diagnosis is made pathologically, the tumor usually appearing with invasive disease (94% in 1 series), and often with metastatic disease (97% in same series). Most common sites of metastases are the lymph nodes, liver, bone, lung, and brain. Due to the high rate of early dissemination, chemotherapy is the mainstay of treatment, with radical cystectomy often performed afterward. The tumor also appears responsive to combined chemotherapy and radiation. Prognosis is generally worse than for urothelial carcinoma. See also Section I: “Bladder Cancer, General.” (Image 9)

SYNONYMS
• Small cell carcinoma
• Neuroendocrine tumor
• Oat cell carcinoma

TREATMENT
• Partial or radical cystectomy
• Platinum-based chemotherapy has achieved partial regression

REFERENCE

BLADDER, TEARDROP

DESCRIPTION
Diffuse pelvic pathology can compress the bladder into a teardrop configuration on various imaging studies, such as urodynamic urography or cystogram. Causes include pelvic hematoma, pelvic herniation, pelvic adenopathy, and enlarged pelvic

vascularity (usually caused by vena cava obstruction). Occasionally, a muscular patient with a hyper trophyd Repose muscle can exhibit this finding.

REFERENCE

BLADDER TRABECULATION AND CELLULES

DESCRIPTION
Trabeculation is a cystoscopic appearance of hypertrophy of smooth muscle bundles in the muscular propria layer of the bladder wall, which occurs over time due to high-pressure voiding in the setting of bladder outlet obstruction. The obstruction may be due to anatomic obstruction such as benign prostatic hyperplasia (BPH) in the adult or posterior urethral valves in the child, or to neurogenic dysfunction such as detrusor-sphincter dysynchrony. It is a manifestation of increased collagen deposition in the bladder wall. More extreme degrees of trabeculation are termed “cellules.” These small pockets are caused when the bladder muscosa is pushed between the collagen and muscle fibers of the bladder wall. Cellules may progress to form an acquired bladder diverticulum. (See also Section II: “Bladder Diverticulum.”) (Image 9)

REFERENCES

BLADDER, VILLOUS ADENOMA

DESCRIPTION
This tumor has a histologic appearance identical to villous adenoma of the colon. It can also be seen in the stomach. Cystoscopically, it appears neoplastic and papillary. Histologically, a mucous-secreting epithelium with goblet cells is seen. It is treated by transurethral resection with possible cystectomy. If invasion is suspected.

REFERENCE

BLADDER WALL CALCIFICATION, DIFFERENTIAL DIAGNOSIS

DESCRIPTION
Bladder wall calcification is a relatively uncommon finding. The differential includes:
• Amiodarone
• Bilharzia (urinary schistosomiasis)
• Cyclophosphamide-induced cystitis
• Encapsulated cysts
• Mitomycin C intravesical treatment
• Tuberculosis
• Urethral carcinoma

REFERENCE

BLADDER WALL THICKENING, DIFFERENTIAL DIAGNOSIS

DESCRIPTION
Bladder wall thickening can be seen on US, CT, or MRI. The differential includes:
• Bacterial cystitis
• Bilharzial infection (urinary schistosomiasis)
• Bladder cancer (urothelial carcinoma)
• Bladder fistula (Crohn disease, diverticulitis)
• Hemorrhagic cystitis
• High-pressure storage voiding (bladder outlet obstruction, neurogenic bladder)
• Systemic lupus erythematosus
• Tuberculosis (Image 9)

REFERENCES

BLASTOMYCOSIS, GENITOURINARY

DESCRIPTION
Blastomyces dermatitidis is endemic in the Ohio, Mississippi, and Missouri river basins. It is an opportunistic infection in immunosuppressed patients, particularly associated with prolonged steroid use (>2 mo), HIV, solid tumors treated with radiation or chemotherapy, and end-stage renal and hepatic disease. GU blastomycosis tends to involve the prostate and epididymis, and produces voiding complaints. Genitourinary disease may be seen in 20–30% of disseminated infections. Prostatic abscesses can be seen, up to 30% can have epididymal involvement. GU blastomycosis is a manifestation of systemic disease; it has been reported to be transmitted by sexual relations to the GU system of the partner. Diagnosis may be made by isolation of fungus from the urine, semen, or tissue. Detection of Blastomycosis A antigen by immunodiffusion may be helpful in diagnosis. Other serologic testing with enzymeimmunosassay and radioimmunoassay have high sensitivity (85–88%) and specificity (100%).

TREATMENT
• Standard therapy for disseminated infection is long-term amphotericin B
• Long-term ketoconazole (12 mg) at 400 mg/day may be effective for prostatic/lipidicystitis
• Imoconazole may be effective in local uncomplicated infections

REFERENCES
Bleomycin Toxicity

DESCRIPTION

Bleomycin is a combination chemotherapy for testicular cancer as well as cervical, ovarian, SCC, and lymphoma, induces single- and double-strand breaks in DNA called scission. Pulmonary fibrosis (fibroelastic alveolitis) is a potentially lethal toxicity, it can develop 1–4 mo after treatment and has been reported to occur beyond 6 mo. Bleomycin may also cause hypersensitivity pneumonitis and nodular pulmonary densities. Skin changes, alopecia, and stomatitis are common. Vascular toxicity, anaphylaxis, and Raynaud phenomenon have been reported. Clinical indications of pulmonary toxicity may include any of the following: Cough (prolonged), dyspnea, pleural chest pain, fever, tachypnea, sinks, loss of restriction, and hypopnea. Renal insufficiency is a risk factor for bleomycin toxicity (90% eliminated by the kidney).

TREATMENT

- Discontinue drug with suspected bleomycin-induced injury; vincristine may help some cases.
- Attention to minimizing oxygen concentration and hydration status during surgery is essential.

REFERENCE

Blue Diaper Syndrome

DESCRIPTION

Deficit in tryptophan absorption in which the urine contains indoles, giving it a blue color. Similar to Hartnup disease, a chronic course is usual. Hypoglycemia of the optic disc and abnormal eye movements have also been reported.

SYNONYMS

- Familial hypercalcemia with nephrocalcinosis and indurated skin
- Tryptophan malabsorption
- Phenylketonuria

TREATMENT

Low-tryptophan diet; no treatment known for underlying defect.

REFERENCE

Blue Dot Sign

DESCRIPTION

A blue discoloration seen through the scrotal wall when the testes are tented against the skin. Indicates the presence of torsion of the appendix testis itself. If torsion of the cord can be ruled out by skin. It has been reported in lesions with adenoscincoma.

REFERENCE

Blue Nevus (Melanosis), Urologic Considerations

DESCRIPTION

Beige melanotic lesion of the prostate that may be differentiated from multiplicity melanoma. It is usually an incidental finding after TURP. In prostate, the term blue nevus has been used when melanin is confined to atrophic or elongated melanocytes in the stroma, whereas the term melanosis has been used for those prostatic lesions that have melanin in both the stromal melanocytes and glandular epithelium. It has been reported in lesions with adenocarcinoma.

REFERENCE

Body Mass Index (BMI), Urologic Considerations

DESCRIPTION

The BMI is defined as the weight (in kilograms) divided by the height (in meters)². BMI is used to categorize obesity (see table). Higher BMI carries many increased health risks, including diabetes and coronary artery disease. Obesity and elevated BMI have many detrimental effects and associations in urology. Elevated BMI has been shown to be an independent risk factor for incontinence in females and for adverse outcomes in prostate cancer. BMI has been clearly correlated with incidence and risk of formation of renal calculi in both men and women. It has been implicated in ED, with reduction of BMI correlating with improved IIEF score. Increased BMI as a marker of obesity implies increased difficulty in many open, laparoscopic, and percutaneous procedures. A BMI calculator from the NIH is available online at:\n
http://www.nhlbisupport.com/bmi/.

Bone Marrow/STEM Cell Transplantation, Urologic Considerations

DESCRIPTION

High-dose chemotherapy regimens used for bone marrow transplantation and stem cell transplantation are accompanied by multiple toxic side effects. The most common urologic complication is hemorrhagic cystitis (HC), with an incidence ranging from 7–68%. HC is commonly seen in a dose-dependent manner after the administration of cyclophosphamide and Fludarabine. Both medications have the same metabolite, acrolein. HC can further be caused by busulfan, pelvic irradiation, thrombocytopenia, and the presence of a urinary viral infection (adenovirus, BK virus, cytomegalovirus [CMV], polyoma virus). Early onset HC is seen due to acrolein exposure, late HC is associated with viral etiologies. Other possible urologic sequelae of high-dose chemotherapy exposures include bladder fibrosis, fistula, bladder contractures, chronic urinary tract infections, pyelgia, and secondary malignancies. A preservative measure for HC is preservation with 2-merscaptoethane sodium sulfate (Mesaon) and hydration. Catheter drainage and continuous bladder irrigation may prevent acrolein exposure to bladder urothelium. Urinary bladder syndrome and urolc acid stone development are also possible.

REFERENCE

Bone Metastasis, Urologic Considerations

DESCRIPTION

Bone metastasis is a common problem in patients with malignancies. Prostate cancer has a predilection to metastasize to bone but bone metastases are also seen from renal cell carcinoma, osteosclerotic carcinoma, and adrenocortical carcinoma is also seen. An elevated alkaline phosphatase suggests bone lesions. The diagnosis often involves a radiographic bone scan with confirmatory imaging study and possibly biopsy. Bone metastases are associated with pain (which may be severe), pathological fractures, and possible spinal compression (often referred to as skeletal-related events or SRE). These lesions often require treatment independently from the primary tumor. Options for treatment include chemotherapy, surgery, and external beam radiation. Radiation therapy is often highly successful at controlling local bony symptoms and radiosteard carbamates such as strontium-89 are useful for palliation of more extensive bone metastasis. Radium 223 ([223Ra]) an α-emitter has been approved for bone metastases, prostate cancer and can improve quality of life and extend survival in metastatic castrate resistant prostate cancer. In prostate cancer in particular, bisphosphonate therapy such as zoledronic acid, and...
osteoclast targeting agents such as denosumab are used to prevent progression and skeletal-related complications and may be effective at preventing occurrence of bone metastases (Image 0).

REFERENCES

BONE MINERAL DENSITY, UROLOGIC CONSIDERATIONS
DESCRIPTION: Prolonged ADT for prostate cancer is associated with decreased bone mineral density (BMD) and osteoporosis, leading to disabling skeletal fractures. Bisphosphonate therapy (zoledronic acid, alendronate, others), smoking cessation, weight-bearing exercise, and vitamin D and calcium supplementation can help improve BMD during androgen ablation therapy. (See also Section II: "Osteoporosis and Osteopenia, Urologic Considerations.") Some recommend that BMD should be monitored during androgen-deprivation therapy using BMD scans (dual energy x-ray absorptiometry or DEXA).

- T-score: The number of standard deviations (SD) by which the patient’s bone mass falls above or below the mean peak bone mass for a 30-year-old healthy adult. For every 1.0 decrease in T-score, relative risk of fracture increases ~1.5–2.5-fold.
- Z-score: Interpretation of T-scores: Normal: –1 to –2.5; Osteopenia: ≤ –1 to 2.5; Osteoporosis: ≤ –2.5; Severe osteoporosis: ≤ –3 and ≤ 1 fracture

BONE SCAN, UROLOGIC CONSIDERATIONS
DESCRIPTION: The radionucleotide bone scan is a sensitive test for bone metastases and is obtained during the initial staging or in the setting of recidivism or metastatic disease in urologic malignancies (prostate, renal, renal, and adrenocortical carcinoma). A standard bone scan is generally performed by acquiring multiple images of the skeleton 3–4 h after injection of technetium-labeled methylene-diphosphonate (MDA). Due to low specificity, if a lesion is identified, particularly when solitary, further investigation is necessary using confirmatory testing. This may be done with plain radiographs, CT, or MRI. Bone scans are extensively used in prostate cancer to detect and follow bone metastases. In prostate cancer patients with extensive bone metastases, the bone scan may have a “super scan” appearance, in which the focal lesions coalesce to produce diffuse increased uptake. An increase in the contrast between bone and soft tissue and faint or absent renal images are the typical appearances seen on a “super scan.” (Image 0)

RONEY TEST (MARSHALL TEST)
DESCRIPTION: A clinical test used for ~50 yr for the diagnosis of stress incontinence and for the selection of patients for incontinence surgery. As originally described, the test consists of 2 parts:
- The patient coughs with a full bladder, and simultaneous urine loss from the urethra is visually confirmed. The examiner elevates the bladder neck with a finger on either side of the urethra while the patient coughs again.
- If the patient is then continent, the test is considered positive and the patient is thought to have an anatomic defect correctable by surgical excision of the bladder neck. Bonney cautioned that the fingers must be carefully placed to avoid compressing the urethra in the immediate postoperative period.

BORS-COMARR CLASSIFICATION OF VOIDING DYSFUNCTION
DESCRIPTION: Based on observations noted with spinal cord injury patients. The system takes into account 3 main factors:
- Anatomic location of the lesion (upper motor neuron, lower motor neuron)
- Completeness of the lesion (partial vs. complete SCI)
- Presence of residual urine, which would mean “unbalanced,” according to the definition
- Best applied to patients with a complete neurologic lesion after spinal shock has resolved.

BOWENOID PAPULOSIS
DESCRIPTION: Bowenoid papulosis is an uncommon skin lesion affecting the genital, groin, and perianal areas of young, sexually active adult men and women. The histology appearance resembles anogenital actinic keratosis, but the lesions usually follow a benign clinical course, and spontaneous regression is observed. Evolution of the lesions to invasive carcinoma is rare. The papules are asymptomatic, discrete, small (average 4 mm in diameter), flat, reddish violaceous or brown, often cockrocker, and usually have a smooth, warty surface. Many patients have a history of genital infection with viral warts or herpes simplex. Genital warts are primarily caused by HPV types 6 and 11; treatment should be conservative. Individual lesions can be adequately treated with excision, cryosurgery, or laser surgery, much as ordinary warts, without the need for wide surgical excision. Alternatively, lesions may be treated with 3–5 wk with 5% 5-fluorouracil cream or imiquimod cream (QD).

and diminution of the radiation dose to the prostate.

organ, especially in cases of patent foramen ovale, regarding this process are possible injury to the end diagnosed incidentally on imaging studies. 2 concerns frequently involved in embolization. Because of their 0.8 mm in diameter and, due to its small size, is more emboli exist through a patent foramen ovale. The is the lung, but reports of coronary artery and hepatic 0.7–55% of all cases. The most common target organ seed displacement and embolization ranging from Multiple investigations have yielded varying rates of prominent periprostatic veins and traveling centrally. seeds, when placed into periprostatic tissue, have been noted to migrate, at times entering the prostate cancer via image-guided implantation of

Nguyen BD. Cardiac and hepatic seed implant

REFERENCE

BOYARSKY GUIDELINES FOR BPH
DESCRIPTION: To provide reproducible guidelines for the severity of symptoms of prostate, BPH, and LUTS, score questionnaire forms have been developed. Traditional assess questions tool include the Seattle–Maden–Pointer System and the Boyarsky Guidelines. These have been generally replaced by the AUA or IPSS questionnaires, but are used in several ongoing follow-up studies of BPH therapies.

REFERENCE

BOYCE NEPHROTOMY (ANATROPHIC NEPHROLITHOTOMY)
DESCRIPTION: The longitudinal anatomic nephrolithotomy [lens advantage of a nearly avascular plane in the kidney (Bridle white line), which can be used to remove staghorn calculus (Boyce anatrophic nephrolithotomy). The incision site in the lateral posterior surface of the kidney can be accurately identified by injecting indigo carmine in the posterior renal artery branch. Once the capsule is incised, the parenchyma is divided with the blunt end of the knife in the proper plane. Traditionally used for staghorn calculus.

REFERENCE

BRACHYTHERAPY SEED EMBOLUS
DESCRIPTION: Brachytherapy is used to treat prostate cancer via image-guided implantation of radioactive seeds of iodine-125 or palladium-103. These seeds, when placed into periprostatic tissue, have been noted to migrate, at times entering the prominent periprostatic veins and traveling centrally. Multiple investigations have yielded varying rates of seed displacement and embolization ranging from 0.7–55% of all cases. The most common target organ is the lung, but reports of coronary artery and hepatic emboli exist through a patent foramen ovale. The iodine-125 seed measures 4.5 mm in length and 0.8 mm in diameter and, due to its small size, is more frequently involved in embolization. Because of their size, these emboli are often asymptomatic and are diagnosed incidentally on imaging studies. 2 concerns regarding this process are possible injury to the end organ, especially in cases of patent foramen ovale, and diminution of the radiation dose to the prostate.

REFERENCE

BRAND METASTASIS, UROLOGIC CONSIDERATIONS
DESCRIPTION: Brain metastasis disease can be seen with several urologic malignancies, most commonly with renal cell carcinoma and germ cell tumors (GCT). They generally are poor prognostic indicators. Patients may be asymptomatic with occult disease or display neurologic symptoms such as headache, nausea, and vomiting, mental status changes, seizures, or focal signs. Patients presenting with neurologic symptoms and neurologic signs should be worked up for brain metastases. CT Scan is generally quick and readily available, but MRI has higher sensitivity and is better at distinguishing metastases from other intracranial processes. Due to their close impact on quality of life, these often require prompt treatment usually via radiation therapy or surgical removal.

REFERENCE

BRENNER TUMORS
DESCRIPTION: These are tumors of variable malignant potential of the ovary. Extravasation and testicular origins have been reported, and they usually present as an ovarian mass. Light microscopy demonstrates distinctive nests of transitional cells indistinguishable from urothelium. Classified as typical, metaplastic, proliferating, or malignant, these lesions usually stain for carcinoembryonic antigen (CEA). Theorized origin is from a metaplastic process of coelomic epithelium. Usually, surgical removal is used to assess malignant potential.

REFERENCE

BRICKER URETAL ANASTOMOSIS
DESCRIPTION: A direct ureter-to-small bowel end-to-side refluxing anastomosis incorporating full-thickness ureteral and intestinal wall. It is used in local suit construction.

REFERENCE

BRIGHAM SLING (URETHROPERYX)
DESCRIPTION: Used to treat stress incontinence in women. A combined endoscopic needle sling procedure that utilizes a Versa facial strip placed at the bladder neck through a vaginal incision. The facial sling is held in place with needles placed through the anterior abdominal wall, similar to the Scarpel and Raz suspension needle procedures. (See also Section I: "Conventional, Urethra, Adult Female.")

REFERENCE

BRINK SCORE
DESCRIPTION: A digital test of pelvic muscle strength for evaluation of a pelvic muscle exercise program. Factors of perceived pressure, alteration of the vertical plane of the pelvis was timed to form a 3-point scale. Currently used in pelvic floor physical therapy regimens.

REFERENCE

BRITISH TESTICULAR TUMOR CLASSIFICATION
DESCRIPTION: Used mainly in Great Britain, and based on the concept that all nonseminomatous tumors represent displaced, nonorganized embryonic blastomeres and are therefore teratomas. Disperse lesions are classified under a common category. The World Health Organization classification is used in most of the rest of the world.

REFERENCE

BRONCHOGENIC CYST, RETROPERITONEAL
DESCRIPTION: Bronchogenic cysts are congenital abnormalities arising from remnants of the primitive foregut, which gives rise to the respiratory diverticula. Generally asymptomatic and benign, these lesions are often incidentally discovered. The true prevalence is unknown due to their asymptomatic nature. Retroperitoneal location is exceedingly rare with only approximately 60 cases reported in the literature. Most retroperitoneal bronchogenic cysts are located near the left adrenal gland or paraaortic. Anatomopathologic criteria include pseudostratified, ciliated columnar epithelium with cartilage, smooth muscle or serous glands. May become larger over time due to continued epithelial secretion, infection, perforation, hemorrhage, and malignant degeneration are possible and surgical extirpation is recommended. Definitive diagnosis can only be made histopathologically. (See also Section I: "Retroperitoneal Masses, Male, and Cysts.")

REFERENCE

BRUNN BUDS AND NESTS (VON BRUNN NESTS)
DESCRIPTION: Variant of bladder epithelium, noted in the development of normal bladders. Brunn buds are an invagination of surface epithelium into the lamina propria. Brunn buds represent a further invagination of epithelial cells present within the lamina propria of the normal bladder. They are not a normal finding and may represent a cystic lesion. The presence of Brunn buds is used to differentiate between a true and a false cyst. The presence of Brunn buds is used to differentiate between a true and a false cyst.

<table>
<thead>
<tr>
<th>Material</th>
<th>Brand Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Combination of calcium hydroxyapatite (CaHA) and calcium carbonate/hydroxylapatite carrier gel | Coaptite | Calcium is a principal component of human bone and tooth and has been used in multiple orthopedic and dental applications. It is demonstrated bone formation and is soft enough to avoid fibrotic infiltration. 

Gluatarylate cross-linked bovine collagen | GAV Collagen | Highly purified 35% suspension of bovine collagen (95% type I collagen and 1–5% type II collagen). Does not cause granuloma formation or migration to distant body sites. Begins to degrade in 12 wk; completely degraded in 19 mo, but the injected material transforms into living connective tissue. 

Pyrolytic carbon-coated zirconium beads | Durosphere | Nonresorbable pyrolytic carbon-coated zirconium beads are much larger (212–500 μm) than either PTFE or silicone polymer beads. Are suspended in a highly viscous silicone gel, which is soft enough to avoid fibrotic infiltration. 

Ethylene vinyl alcohol (EVOH) | Tegress | Permanently implanted nonpyrogenic, injectable bulking agent (EVOH). The resulting mixture is FDA-approved for management of intrinsic sphincteric deficiency in women. 

Silicone polymers | Macroplastique | Biocompatible and biodegradable implant. The dextranomer microspheres range from 80–250 μm in size. 

Dextranomer microspheres | Deflux | Viscous gel of dextranomer microspheres (50 mg/mL) in a carrier gel of nonanimal stabilized hyaluronic acid, constituting a bioresorbable and biodegradable implant. The dextranomer microspheres range from 80–250 μm in size.

BURCH COLPOSUSPENSION
DESCRIPTION
The pubocervical fascia at the level of the bladder neck is folded to Cooper’s ligament bilaterally, usually through a parametrial incision and a retropubic exposure. It is used in treatment of stress incontinence in women.

REFERENCE

BUSCHKE-LOWENSTEIN TUMOR
DESCRIPTION
Benign malignant perineal or perianal lesion, which may be large and exophytic. May cause urethral erosion and fistulae. Can be very locally invasive and metastasize to lymph nodes. Microscopically, broad rete pegs, filled with benign squamous cells and surrounded by a layer of inflammatory cells, are noted. A possible role of HPV 6 and 11 in the development is theorized. Treatment is by local excision after proven diagnosis. See also Section 1: “Condyloma Acuminata (Venereal Warts)” and “Penis, Lesion.”

SYNONYMS
• Verrucous carcinoma
• Giant condyloma acuminata

REFERENCE

CALCYPHALYSIS
DESCRIPTION
Calciphylaxis, also known as calcific uremic arteriosclerosis, is a rare cutaneous systemic disease seen with advanced chronic kidney disease. The classical cutaneous picture is a necrotic and progressive skin ulcer (necrotic pattern), primarily in the lower legs and susceptible to local infection. It is a product of mural calcification and occlusion of cutaneous and subcutaneous arteries and arterioles. Calciphylaxis has been reported to occur in 1–4.5% of patients in dialysis, mostly in hemodialysis, with predominance in patients who are obese, diabetic, or have liver disease, are using systemic corticosteroids or have a calcium-phosphate product of >70 mmol²/L. Calciphylaxis is reported to be a lethal complication with an estimated 1-yr survival rate of 48.8%. Mortality is usually reported as a result of local and systemic infections and sepsis.

REFERENCE

REFERENCES

CALCIFICATIONS, ADENOMAL AND PELVIC TUMOR
DESCRIPTION
Adenomatous and pelvic calcifications are a common finding on plain radiographs and CT. The differential is very broad and includes renal, adrenal and bladder calculi, vascular calcifications (atherosclerosis and phlebothrombosis), calcified tumors, lymph nodes, seminal vesicles, vas deferens, and infectious processes (TB) (Image 4).

REFERENCE

CALCIFICATIONS, BLADDER
DESCRIPTION
Bladder calcifications on CT or plain radiography:
• Intraluminal: Bladder calculi, 7% of bladder calcifications, may be small stones, encrusted cystitis, foreign body, iatrogenic (postop sutures, retained prostate chips, catheter fragments, hair [due to chronic self-catheterization], following intravesical BCG or mitomycin)
• Bladder wall: Infections (tuberculosis, schistosomiasis), squamous cell carcinoma, cyclophosphamide-induced cystitis, prior radiation treatment, amyloidosis

REFERENCE

CALCIFICATIONS, PROSTATE
DESCRIPTION
Calcifications within the prostate are fairly common and can be detected in over 50% of older men. In 1 series, of normal men calcifications were found in 23.1% of men aged 20-29 yr compared with 83% for men aged 60-69 yr. Prostatic calcification or calcified nodules are rare. On Doppler imaging they create a prominent “twinkle” artifact. Prostatic calculi usually coexist with prostatitis or BPH in elderly men. BUN along with sodium is thought to be decreased in the setting of increased renal clearance. In renal failure, BUN and creatinine levels are increased, and anemia is usually associated. With anemia, BUN levels decrease in patients with renal disease (diabetic nephropathy, amyloidosis, chronic kidney disease). The serum BUN level depends on both the rate of production and the rate of renal clearance. A decreased level of BUN in renal failure is due to loss of renal mass, and it is not an indication of adequacy of dialysis treatment. Amyloidosis, cyclophosphamide-induced cystitis, prior radiation treatment, amyloidosis

REFERENCE

CALCIFICATIONS, RENAL
DESCRIPTION
May represent calcified renal calculi or calcified cystic or solid renal neoplasms. RCC is detectable on plain radiography and calcified renal calculi can be identified on plain radiographs and CT. The differential is very broad and includes papillary tip calcifications, calcified renal pelvis TCC, nephrocalcinosis, calcified renal artery, and tuberculosis (Image 4).

REFERENCE

CALCINOSIS, IDIOPATHIC SCROTAL
DESCRIPTION
Occur in pre-existing epididymal cysts or in the testis without cysts. Usually affects young men. Multiple cysts ≤2 cm are not uncommon. Calculations range in size from a few millimeters to 3 cm. They may represent epididymal cysts that have, over time, lost their normal wall and calcified. Surgical excision is curative if symptomatic.

REFERENCE
Oral calcium supplementation may be used for a variety of conditions, including osteoporosis. Because calcium carbonate and calcium phosphate are widely used but poorly absorbed from the intestinal tract, these can increase urinary calcium excretion and promote calcium oxalate/phosphate stone disease. Calcium citrate (Citracal) has 950 mg of calcium citrate and 200 mg of elemental calcium in each tablet and increases urinary calcium excretion. However, this formulation also increases urinary citrate excretion, which potentially offsets the lithogenic potential of the calcium supplement–induced hypercalciuria. If calcium supplementation is to be considered to prevent osteoporosis, calcium citrate preparations should be used. In women with a history of stone disease, consider a 24-hr urine collection to identify those who will become or remain hypercalciuric while receiving calcium citrate or slow-release potassium phosphate can be used.

CAMEY I AND II ORTHOTOPIC URINARY DIVERSION

DESCRIPTION In the Camey I procedure, a 40-cm segment of the ileum is chosen for an orthotopic urinary diversion that can reach the urethra. A subcutaneous ventral ileal anastomosis is carried out on each end of the final segment. In the Camey II version, the initial Camey I diversion is modified by using 65 cm of ileum, which is detubularized along its antimesenteric border. It is folded into a U-shape configuration, the adjoining sides of the U are sutured, and the resulting bowel is then folded again to create a pouch anastomosed to the urethra with a Lefort ileal ureterostomy.

CANAL OF NUCK HYDROCELE AND CYST (FEMALE HYDROCELE)

DESCRIPTION In the female, the labia majores are homologous to the scrotum in the male. The labia majores contain the terminal portion of the round ligaments of the uterus and an obliterated remnant of peritoneum similar to the tunica vaginalis, which may persist as the canal of Nuck. A hydrocele (fluid collection) may rarely form in the canal of Nuck.

CANDIDIASIS—CUTANEOUS, EXTERNAL GENITALIA

DESCRIPTION Candida albicans, the most common Candida fungus, rarely colonizes normal skin. Risk factors include the elderly, damaged skin, diabetes, broad-spectrum antibiotic use, steroids, pregnancy, and immunosuppression. Can involve warm, moist areas such as distal urethra, scrotum, inguinal region, glans penis of uncircumcised male and causes burning, itching, redness, dysuria, and pruritis in females (vulvovaginitis). Vesiculobulbar plaques that enlarge and rupture can progress to maceration and erythema. There are distinct nod borders, often with satellite lesions with vesicular discharge being white and thick. Microscopic exam of scrapings or discharge with potassium hydroxide or Gram stain reveals hyphae/pseudohyphae. (For systemic candida, see Section 3, “Fungal Infections, Genitourinary.”)

TREATMENT

• Keep affected areas dry and exposed to air
• Men: Topical Nystatin, 100,000 U/L, microscopic cream QOD
• Women: microscopic cream QOD
• Avoid tight or restrictive clothing
• Women: Nystatin oral Solution or Microconazole cream 100 mg for 3–7 days, others
• More severe infections may require long-term ketoconazole

CAPTOPRIL TEST

DESCRIPTION As a functional test for renovascular hypertension, plasma renin activity (PRA) is measured before and 1 hr after the administration of 20 mg of captopril. The test is considered positive if all of the following occur: Postcaptopril PRA > 12 ng/mL/h, an absolute increase in PRA > 10 ng/mL/h, and a 400% increase in baseline PRA (150% increase if the baseline PRA was >3 ng/mL/h). A positive captopril test points to renovascular hypertension. The test has a sensitivity of ~74% and a specificity of 89%. All diuretics and ACE inhibitors must be discontinued 1 wk prior to the test, and a normal or low-sodium diet is necessary.

CARCINOID TUMORS, GENITOURINARY

DESCRIPTION Very rare in the GU tract, carcinoid tumors have been described in the kidneys, ovaries, uterine cervix, urethra, testes, and bladder, and may have associated carcinoid syndrome. They are usually small, 5–10 mm, and rarely metastasize; carcinoma, adenocarcinoma, and carcinoid tumors are the most common histologic types. The most common sites of occurrence are the bladder, ureter, and renal pelvis.

CARCINOSARCOMA, BLADDER

DESCRIPTION Rare tumor exhibiting elements of epithelial and mesenchymal origin. These usually are fast growing, invasive tumors. Epithelial elements are typically TCC, but they can be any of the other tumor types. Mesenchymal elements are usually spindle cells with evidence of chondroid, osteoid, smooth muscle, or rhabdomyoblastic differentiation. Usually presents with painless, gross hematuria.

TREATMENT

• Transurethral resection or radical cystectomy, as appropriate
• Chemotherapy and radiotherapy for metastatic disease, but outcomes are poor (Image 10)

Carcinoma, Prostate

**DESCRIPTION**
Very rare tumor, similar to the carcinomas of the bladder. These tumors are mixtures of epithelial and sarcomatous elements. The epithelial element in the prostate, however, is adenocarcinoma. Most differentiate from colloid tumors, which are separate coexisting tumors of differing cell types. True carcinomas have an intermediary of cells in the same tumor. Has been described following radiation therapy. Treatment is RR, if organ-confined.

**REFERENCES**

Carney Syndrome (Carney Complex)

**DESCRIPTION**
Also called familial myxoma, the syndrome is characterized by skin pigmentary abnormalities, myxomas, endocrine tumors or overactivity, and schwannomas. Primary pigmented nodular adenocortical disease or PNAAD, which causes Cushing syndrome, is the most frequently observed endocrine tumor in Carney Complex or CNC, occurring in approximately 25%. Pale brown to black lentigines are the most common presenting feature of CNC, and typically increase in number at puberty. Cardiac myxomas occur at a young age. Large-cell myofibroblastomas of the GISTs of the stomach, lung chondroma, paraganglioma, adrenal gland, leiomyoma are syndrome-defining tumors. Of the classic triad, GIST is the most common presenting lesion (75%), followed by lung chondroma (15%) and paragangliomatous tumor (10%). 1/3 of patients had a normal serum PMS level, 1/3 had low serum PMS level, and 1/3 had elevated serum PMS level.

**REFERENCES**

Carcinoma, Urethral

**DESCRIPTION**
An inflammatory lesion of the distal urethra that usually presents as a non-cavitating bladder mass in the postmenopausal woman. Usually reassembles in appearance and covered by mucosa, the lesion protrudes from the urethral meatus. The lesion may thrombose or necrose and may present with spotting of the underwear or even pain. Treatment may involve local estrogen replacement or simple excision. Excision should be considered for any atypical appearing lesions as pathologically significant lesions such as melanoma have been known to mimic this lesion. (See also Section 1: “Urethra, Mass.”)

**REFERENCES**

Causal Procedure

**DESCRIPTION**
A variant of the Yamp-Mont real tube, which is often too short to reach from the bladder to the skin surface. This procedure involves a long (12 cm) catheterizable tube (12–16 Fr) from a short (3.5 cm) segment of bowel, usually ileum. It was designed to take the place of the appendix or colon as a continent channel for intermittent catheterization of the bladder utilizing the Mitrofanoff principle. To increase the canal length, as may be necessary in obese children, Caasle used an intestinal segment that is twice as long, partially split in the middle, and then opened the segment in a spiral fashion on opposite sides to make a longer strip that can be tabulated in continuity. The long-term results of the Caasle tube are comparable to those of the appendix and Yamp-Mont tube in terms of durability, continence, and complication rate (Image 9).

**REFERENCES**

Catenary Syndrome

**DESCRIPTION**
Synonym of tumors affecting at least 5 organs, the stomach, the lung, the paragangliotic system, the adrenal and the endocrine system. Generally seen in young females, 80% of patients present before age 30 and 85% are females. Gastrointestinal stromal tumors (GIST) of the stomach, lung chondroma, paraganglioma, adrenal adenoma, phaeochromocytoma, and epithelial leiomyoma are syndrome-defining tumors. Of the classic triad, GIST is the most common presenting lesion (75%), followed by lung chondroma (15%) and paragangliomatous tumor (10%). 1/3 of patients had a normal serum PMS level, 1/3 had low serum PMS level, and 1/3 had elevated serum PMS level.

**REFERENCES**

Cavernosography

**ADMISSION**
A test used to evaluate veno-occlusive dysfunction. It is performed by the injection of contrast material into the corpora cavernosa after the injection of a pharmacologic agent, such as papaverine, to stimulate relaxation. Any evaluated leakage of contrast material outside the corpora could be a defect in the veno-occlusive mechanism.Typical leak points include the glans, corpus spongiosum, superficial or deep dorsal veins, and cavernous and curvular veins.

**REFERENCES**

Caudo Equina Syndrome

**DESCRIPTION**
A term applied to the clinical picture resulting from compression of the cauda equina (or “horse tail”) by nerve roots or discal material to the level of spinal cord termination. This indicates peripheral sensory loss, loss of anal and urethral sphincter control, and loss of ejaculation. The most common causes of this condition are posterior, central lumbar disc herniation, spinal stenosis, tumor, and trauma. Caudo equina syndrome is present in 1–5% of all prolapsed lumbar discs. Characteristically, the affected patient has an acontractile detrusor with no bladder sensation, and often an inactive sphincter EMG. Treatment consists of surgical relief of pressure, although the neurological deficit can be permanent. On follow-up urodynamics, an acontractile detrusor and variable EMG activity may persist.

**REFERENCES**

Caudal Regression Syndrome

**DESCRIPTION**
First described by Duhamel in 1961, this syndrome is caused by disorder embryogenesis during the 4th–5th wk of gestation. It features a wide array of abnormalities: consisting on the vertebral, urogenital and lower spine areas. Severe cases demonstrate fusion of the lower limbs, sacral agenesis, imperforate anus, and absent GU tract (except gonads). In less severe cases, imperforate anus and/or sacral agenesis are seen. In these, in turn, are associated with voiding dysfunction, Veicoceutal reflux is also quite common. Managing the myriad problems requires a multidisciplinary approach.

**SYNONYMS**
- Caudal dysplasia sequence
- Urorectovaginal syndrome

**REFERENCES**

Cystectomy

**DESCRIPTION**
Removal of the urinary bladder. May be performed in cases of bladder cancer, bladder fistula, non-functioning bladder, or other indications. It is performed by a urologist and involves the removal of the bladder and a portion of the posterior abdominal wall. The incision is made through the abdominal wall, and the bladder is removed. The ureters are implanted into the iliac vessels. A urinary diversion is created to allow for urination. The procedure may be performed open or laparoscopically. It is typically indicated for localized or recurrent bladder cancer.

**REFERENCES**

Cat Eye Syndrome

**DESCRIPTION**
Also called Slocum-Fraccaro syndrome, a rare, congenital syndrome with features of colobomas of the iris and nasal area with fissurae, downward-sloping palpebral fissures, preauricular pits and/or pili, frequent occurrence of heart and renal malformations, and normal or near normal mental development. The ulterior abnormalities reported include various renal malformations, eg, absence of 1 or both kidneys, hydronephrosis, supernumerary kidneys or renal hypoplasia, choicic pelvirectal, horacic kidney, hydronephrosis, and veicoceutal reflux, and an associated additional chromosome 22. Close monitoring for possible pelvirectal is warranted.

**REFERENCES**
CAVERNOSOMETRY

DESCRIPTION
A test used to evaluate veno-occlusive leak in ED. Performed by 1st stimulating erection, either by visual or injection of a pharmacologic agent. Intracorporal pressure measurements are then recorded. The inability to raise intracorporeal pressure to levels equal to systolic blood pressure or a rapid drop of pressure after cessation of injection is indicative of veno-occlusive dysfunction.

REFERENCE

CECIL URETHRAL STRICTURE REPAIR

DESCRIPTION
The stricture is 1st excised, and the defect is closed with urethral skin. In the 2nd stage, a neourethra is created by tabularizing the urethra and represent a subtype of ureterocele.

REFERENCE

CECOUREROTEOCLE

DESCRIPTION
A ureterocele is a congenital saccular dilatation of the terminal portion of the ureter. Cystoureteroceles are elongated beyond the ureteroureteral orifice by tunneling beneath the trigone and the urethra and represent a suble of ureterocele.

REFERENCE

CELLO SCROTUM
DESCRIPTION
A described function medical condition in which a cello player irritates the scrotum. It is a dinosaur.

REFERENCE

CEREBRAL PALSY, UROLOGIC CONSIDERATIONS

DESCRIPTION
Cerebral palsy is a broad term describing a generally nonprogressive brain dysfunction occurring perinatally (up to age 3) by some definition with the consequences of long-term cerebral dysfunction. The etiology is thought to involve injury, infection, or a period of anoxia. The range of symptoms is broad, from mild mental retardation to severe developmental and motor delay. Surprisingly little is written about the exact urologic manifestation of cerebral palsy, and even the incidence of urologic dysfunction is unclear. In some series, up to 36% of patients with cerebral palsy had lower urinary tract dysfunction. In another series, the most common symptom involved incontinence (75%), frequency (56%), and urgency (37%). The most common urodynamically defined dysfunction was detrusor overactivity (DSO) (87% of those undergoing urodynamics), with 25% of these exhibiting apparent outlet resistance dysuria. (See also Section I: “Neurogenic Bladder: General Considerations.”)

REFERENCE

CERVICAL CANCER, UROLOGIC CONSIDERATIONS

DESCRIPTION
Metastatic complications regarding cervical cancer treatment are well documented. If pelvic exenteration is performed, urinary diversion is obligatory. Radical hysterectomy has risks of ureteral and bladder damage, which may result in a fistula. Radiation therapy also can be mobilized, with radiation cystitis, ureteral stricture, and fistula possibly resulting. The increased risk of bladder cancer after radiation therapy is controversial. (See also Section VII: “TNM Staging.”)

REFERENCE

CHANCROID
DESCRIPTION
An STD/STI caused by Haemophilus ducreyi and relatively uncommon in the United States but a concern (STID/STI) in developing countries. The combination of a painful genital ulcer and tender suprapubic iliac adenopathy suggests the diagnosis of chancroid. H. ducreyi is a gram-negative cocccobacilli and resembles a “school of fish” on Gram stain (clumping in long parallel strands). Incubation is 4–10 days and the ulcer is 1–2 cm, necrotic, purulent, and ragged with radiation adenopathy in over 50%.Sites include the dorsal penis in men and labia and vagina in women. Diagnosis is based on clinical findings. No FDA-cleared PCR test for H. ducreyi is available in the United States, but such testing can be performed by clinical labs that have developed their own PCR test and have conducted a CLIA verification study. A probable diagnosis of chancroid, for both clinical and surveillance purposes, can be made if all of the following criteria are met: (1) the patient has 1 or more painful genital ulcers; (2) the patient has no evidence of Treponema pallidum infection by darkfield exam of ulcer exudate or by a serologic test for syphilis performed at least 7 days after onset of ulcer; (3) the clinical presentation, appearance of genital ulcers and, if present, regional lymphadenopathy are typical for chancroid; and (4) a test for HSV performed on the ulcer exudate is negative.

TREATMENT
Recommended treatment is a single-dose of azithromycin 1 g PO or ceftriaxone 250 mg IM or ciprofloxacin 500 mg PO BID x 3 days (contraindicated if pregnant) or tetracycline or erythromycin base 500 mg PO TID x 7 days. (See also Section I: “Sexually Transmitted Infections [STIs] and Sexually Transmitted Diseases [STDs, General.”)

REFERENCE

CHARCOT-BOETTCHER CRYSSTALS AND FILAMENTS
DESCRIPTION
A normal ultrastructural component of human Semel cells observable with electron microscopy. Can be used to establish Sertoli origin in atypical sex cord-stromal tumors.

REFERENCE

CHARGE ASSOCIATION
DESCRIPTION
CHARGE refers to the association of coloboma, congenital heart disease, choanal atresia, retardation growth and development, structural brain abnormalities, and ear abnormal. Of urogenital interest is the association with genital hypoplasia, secondary to low androgen levels. Mostly sporadic, but a familial form has been reported. It is theorized to originate during a developmental error of neural crest elements at about the 6th wk. Early management of sensory defects is important. Androgen replacement is used for genital hypoplasia.

REFERENCE

CHEMOTHERAPY TOXICITY, UROLOGIC CONSIDERATIONS
DESCRIPTION
All chemotherapeutic agents have potentially significant toxicities and side effects. For the urologic surgeon, certain toxicities may be more commonly encountered. Both commonly used chemotherapeutic regimens for urothelial carcinoma, methotrexate/vinblastine/adriamycin/cisplatinum and gemcitabine/cisplatinum have significant nephrotoxicity, which can be problematic for older patients or patients with renal insufficiency or malignant ureteral obstruction. Blinomycin, used for nonmalignant germ cell tumors as part of the bleomycin, etoposide, cisplatin (BEP) regimen causes pulmonary toxicity. If postchemotherapy retroperitoneal lymphadenectomy is necessary, the anesthesiologist should be counseled to avoid high inspired oxygen concentrations and minimize crystalloid fluid resuscitation, as these factors may exacerbate bleomycin-related pulmonary toxicity. Cyclophosphamide may cause hemorrhagic cystitis, because of its toxic downstream metabolites, acrolein, which is excreted into the urine. Administering the agent Metha decreases this toxicity. Cyclophosphamide also increases the risk of subsequent bladder cancer up to 9 fold. (See also Section II: “Blinomycin Toxicity.”)
CHRONIC KIDNEY DISEASE

DESCRIPTION
Chronic kidney disease (CKD) is a diagnosis that can be made in either a man or a woman. Guidelines define CKD as FFR for at least 3 of the preceding 6 mo in the absence of other identifiable causes. Older terms used include prostatodynia and abacterial prostatitis.

Males: Guidelines define CP/CPPS for at least 3 of the preceding 6 mo in the absence of other identifiable causes. Sometimes referred to as chronic prostatitis/chronic pelvic pain syndrome (CPPS/CP) is a chronic syndrome. The symptomatology is based on urologic symptoms and/or pelvic pain or discomfort. While the term “prostatitis” is often used it is unclear to what degree the prostate is the cause of symptoms. Nonbacterial prostatitis occurs in men with no history of urinary tract infection and negative bacterial cultures of urine and prostatic fluid. The inflammatory type (PH I.A. Chronic prostatitis/pelvic pain syndrome, (inflammatory) presents with GU or rectal pain or voiding symptoms; the prostatic fluid contains inflammatory cells. Men with the noninflammatory type (PH II.B. Chronic prostatitis/pelvic pain syndrome, noninflammatory), whose prostatic fluid has no leukocytes, have similar symptoms, but pelvic pain is usually the predominant complaint. (See section I: Prostatitis, Chronic, Nonbacterial, Inflammatory (NH CP/CPPS III A), Section I: Prostatitis, Chronic, Nonbacterial, Noninflammatory (NH CP/CPPS III B), Section II: Pelvic Pain, Male.)

TREATMENT
- Empic 8–12 wk course of antibiotics
- Consider prostatitis massage. If no response
- High-dose α-blockers (Flomax, Cardura, Hytrin)
- Anti-inflammatory agents, lifestyle changes, stress reduction, holistic therapies

REFERENCE

CHRONIC PELVIC PAIN SYNDROME (CPPS) IN FEMALES

DESCRIPTION
A radiologic change in the bladder wall caused by detrusor or muscle hypertrophy and fibrosis as a result of detrusor-sphincter dyssynergia. Also called proctococele appearance.

REFERENCE

CHRONIC PROSTATITIS/PELVIC PAIN SYNDROME (CPPS/CP) IN MALES

**CIRCUMCISION, FEMALE**

**DESCRIPTION**
Female genital cutting, also known as female circumcision or genital mutilation, is a culturally determined practice, predominantly performed in parts of Africa and Asia. The World Health Organization classified female genital cutting into 4 types of procedures.

- **Type I** consists of excision of the prepuce, with or without excision of part or all of the clitoris.
- **Type II** involves clitoridectomy and partial or total excision of the labia minora.
- **Type III**, or infibulation, includes removing part or all of the external genitalia and reapproximation of the remnant labia majora, leaving a small neocervix.
- **Type IV** involves other forms of injuries to the genital region including pricking, piercing, stitching, burning, scraping, or any other manipulation of the external genitalia.

**TREATMENT**
- Short-term urologic problems with the procedure include urethral edema and urinary retention potential. Long-term problems include dysmenorrhea, dyspareunia, and increased risk of urinary tract infection.

**REFERENCE**
Nour NM. Female genital cutting (circumcision). In UpToDate.com, Accessed March 8, 2014.

**CISPLATIN TOXICITY**

**DESCRIPTION**
Cisplatin is a very commonly used antitumor agent with significant adverse effects. Administered in urology for urethral carcinoma and testicular cancer, its nephrotoxicity is cumulative and dose-dependent, and commonly limits use. Other significant effects include myelosuppression, ototoxicity, GI disturbances, and neurotoxicity. See also Section II: “Chemotherapy Toxicity, Urologic Considerations.”

**TREATMENT**
- Antidiuretic has been used to limit toxicity.

**REFERENCE**
Nour NM. Female genital cutting (circumcision). In UpToDate.com, Accessed March 8, 2014.

**CHYLOCELE**

**DESCRIPTION**
Also called chylous hydrocele, chylocele is a rare form of lymphatic fluid drainage into the tunica vaginalis around the testis. The fluid is usually described as milky and contains leukocytes. This may result from lymphatic disruption secondary to diseases such as filariasis. Filariasis affects 120 million people in >80 countries and is caused by Wuchereria bancrofti, which is transmitted by mosquitoes. Chyloceles usually do not resolve after needle aspiration and require the underlying cause to be surgically or medically addressed. Freedom from infection at the time of surgery is critical for a favorable outcome. (See also “Section I: Scrotum and Testicle, Mass.”)

**TREATMENT**
- Vertical scrotal incision with complete excision of tunica vaginalis to use.
- Orchidectomy and choridectomy for severe cases
- Medical treatment of filariasis (diethylcarbamazine, ivermectin, praziquantel)

**REFERENCE**

**CHRONIC PROSTATITIS SYMPTOM INDEX (CPSI)/NIH-CPSI (NATIONAL INSTITUTES OF HEALTH CPSI)**

**DESCRIPTION**
The National Institutes of Health Chronic Prostatitis Symptom Index (NIH-CPSI), a reliable validated instrument developed by the NIH Chronic Prostatitis Collaborative Research Network to aid in the quantification of chronic prostatitis symptoms. The NIH-CPSI is intended for clinical practice as well as research protocols. The instrument contains 9 questions. The major domains relate to pain (location, severity, frequency), the nature of voiding (irritative and obstructive symptoms), and the impact of prostatitis on quality of life. The goal of this multi-institutional collaborative effort was to define and measure the symptoms of chronic prostatitis and their impact on the daily lives of patients. The test is self-administered and can be completed in 5 min. Higher scores indicate worse outcomes in all domains, with a possible maximum score of 43. (See also Section I: “Prostatitis, Chronic Bacterial.”)

**REFERENCES**

**CHURG-STRAUSS SYNDROME**

**DESCRIPTION**
Also called allergic angiitis and granulomatosis, this is a vasculitis characterized by extravasatory microscoplic granulomas in the large, heart, GI tract, and skin. Histologically, necrotizing and eosinophilic infiltrate is accompanied by histiocytes are seen. Both necrotizing and eosinophilic granulomatous vasculitis usually involve small arteries and veins, often with a history of atopy. Patients present with fever and weight loss. Eosinophilia, anemia, and an elevated ESR are found. The prostate may be involved by the granulomatous process. Treatment involving corticosteroids with cytotoxic drugs is being investigated.

**REFERENCE**
DESCRIPTION
Anatomically the clitoris is composed of the glans clitoris and the crus, its dimensions are generally independent of BMI, age, and height. Average length of the glans clitoris is 5.1 ± 1.4 mm. Total average of clitoral length from the tip of the glans to the insertion of the crus on the pubis is 16.0 ± 4.3 mm. Multiparous women have slightly larger clitoral dimensions than nulliparous women with a total length on average 0.9 mm greater and a glans length 0.5 mm greater. (See also Section II: “Clitoromegaly.”)

REFERENCE

CLITORAL PRIAPISM
DESCRIPTION
A rare condition that is associated with an extended duration of clitoral erection due to local engorgement of clitoral tissue causing clitoral or vulvar pain. The prolonged erection is not associated with sexual stimulation, and can last from minutes to days. It has been associated with medications: α-blockers, inhibitors of serotonin reuptake (SSRIs antidepressants), and non-SSRI antidepressants and with TCC: obstructing venules and lymphatic outflow. Stopping the offending agent can result in resolution within 24–72 h. Other treatments include: Imipramine, NSAIDs, ice packs, spasms, and, rarely, intracavernous injection of alprostadil. (See also Section II: “Clitoromegaly.”)

REFERENCE

CLITOROMEGALY
DESCRIPTION
Abnormal enlargement of the clitoris is most frequently seen in children born with chromosomal abnormalities. It can also be seen in constitutional growth disorders, such as gigantism or acromegaly. It is most commonly a manifestation of CAH. The underlying cause must be addressed. (See also Section II: “Disorders of Sexual Development-CAH.”)

REFERENCE

CLOSTRIDIUM DIFFICILE COCCIDIOIDOMYCOSIS, GENITOURINARY
DESCRIPTION
A test sometimes used to rule out pneumococcal infection. Clindamycin (0.3 mg) is administered and plasma pneumococcal levels are then measured. Those patients with essential hypertension with an elevation of nonpneumococcal levels will experience a 50% decrease in this carotid sinus reflex level. Patients with pheochromocytoma will not be suppressed. Patients should not be taking diuretics, β-blockers, or tricyclic antidepressants; α-blockers do not interfere with the test.

REFERENCE

CLITORAL LENGTH
DESCRIPTION
An enlarged clitoris is most frequently seen in children born with chromosomal abnormalities. It can also be seen in constitutional growth disorders, such as gigantism or acromegaly. It is most commonly a manifestation of CAH. The underlying cause must be addressed. (See also Section II: “Disorders of Sexual Development-CAH.”)

REFERENCE

CLOSTRIDIOIDES DIFFICILE COLITIS, UROLOGIC CONSIDERATIONS
DESCRIPTION
Also known as pseudomembranous enterocolitis, this is a potentially life-threatening infection of the colon due to overgrowth of C. difficile. It can be precipitated by antibiotic therapy – most commonly fluoroquinolones, clindamycin, cephalosporins, and penicillins – but any antibiotic can be implicated. This suppression of normal bowel flora by antibiotics and overgrowth of C. difficile has been reported in association with bowel preparation prior to elective surgery, as well as in addition to the use of antibiotics for any indication. Watery diarrhea and abdominal pain are the main symptoms of C. difficile infection, but it can range from asymptomatic carrier state, diarrhea with colitis, or pseudomembranous colitis (endoscopic evidence of “pseudomembranes”), to severe life-threatening disease with toxic megacolon. Low-grade fever and leukocytosis are common. It is diagnosed by clinical endoscopic findings, culture of organism, or detection of toxin in stool. Enzyme immunoassay (EIA) allows the direct detection of C. difficile toxin and is the test of choice.

TREATMENT
• Removal of antibiotic therapy, if antibiotic therapy is essential, attempt to use an agent with lesser likelihood of causing C. difficile overgrowth. (aminoglycosides, macrolides, sulfonamides, tetracycline, or vancomycin).
• Metronidazole (500 mg TD or 250 mg QD) is recommended as initial treatment of less severe cases, if needed, IV metronidazole 500 mg q8h; treat for 10–14 days with follow-up toxin assay.
• Alternatively, oral vancomycin 125 mg QID.

REFERENCE

CLOSTRIDIUM DIFFICILE INTESTINAL SYNDROME
DESCRIPTION
The radiologic appearance on an intravenous urogram (IVU) of an intravesical ureterocele of a single ureter in an adult, also called spring onion sign. The dilated ureterocele, filled with contrast material, protrudes into the bladder, which is also filled with contrast material, but is separated from it by a thin radiolucent halo. The ureterocele might be congenital or acquired, as in cases of trauma or inflammation.

REFERENCE

COCCIDIOIDES DIFFICILE, GENITOURINARY
DESCRIPTION
Outbreaks of Coccidioides immitis infection are common when people are exposed to soil that contains the spore. An opportunistic infection more common in patients <5 and >50 yo. It is associated with AIDS, cerebrospinal, and chemotherapeutic for malignancy. After pulmonary inoculation, the patient can develop erythema nodosum (valley bums or valley fever). Chest radiographs demonstrate infiltrates with cavitation. Serologic tests are available to help establish the diagnosis. Disseminated disease involves the kidney in up to 65%, the adrenal in 16–32%, and the prostate in 6%. Renal coccidioidomycosis may cause similar changes, as seen in renal TB (mottled calyces, hyperechoic lesions, ureteral stricture, and calcifications). Prostatic infection with occasional abscesses and clot infections with fistulae have been reported. Epididymal and prostatic involvement can demonstrate necrotizing and nonnecrotizing granulomas. Therapy includes up to 2 g of amphotericin B with 1 year of ketoconazole (200 mg)
COHEN (“CROSS-TRIGONAL”) URETERAL REIMPLANTATION

REFERENCE

COLOM AND RECTAL CANCER, UROLOGIC CONSIDERATIONS
DESCRIPTION
Colon cancer may present as locally invasive lesions that involve the bladder and/or prostate. En bloc resection (pelvic exenteration) of the bladder and rectum is sometimes indicated. In colorectal malignancies, a 2–12% incidence of ischemic extension into the adjacent organs has been reported, with the bladder as the most commonly involved organ. In women, the interruption of the uterus between the colon and bladder makes the incidence lower. In cases of more proximal colon cancers, ureteral and renal involvement may require localization with ureteral catheters. After extensive colorectal dissection, extrapelvic and bladder dissection may occur secondary to disruption of the pelvic plexus up to 70% of the time. (See also Section VII: “Urologist-Bladder.”) (TNM.)

REFERENCE

COLUMN OF BERTIN, HYPERTROPHIED
DESCRIPTION
A normal anatomic structure of the kidney, which, if enlarged, can be mistaken for a renal mass. It normally appears as granular material in the renal sinus, which is simply cortex. The column of Bertini is located between the pyramids. (See also Section II: “Nuclear Pseudotumors.”)

REFERENCE

COMPARTMENT SYNDROME, UROLOGIC CONSIDERATIONS
DESCRIPTION
Compartment syndrome is defined by the rise in pressure in a tissue compartment compromising circulation, can result in devastating consequences, especially in the urologic setting. Reports of compartment syndrome leading to rhabdomyolysis, renal failure, and limb loss have been reported with the dorsal lithotomy position, flank position during open or laparoscopic procedures, prolonged reconstructive pediatric procedures, and urothelial and penile surgeries. Recently there has been an increase in reports relating to robotic prostatectomy. In abdominal compartment syndrome, a Foley catheter can be used to provide continuous abdominal compartment pressure readings.

The etiology of compartment syndrome is multifactorial and prevention is the mainstay of treatment. Positioning and other efforts to prevent acute lower extremity compartment syndrome include limiting the time of leg elevation, positioning the leg below the level of the arium and postoperative monitoring of patients at risk. Pulse oximetry to detect hypoperfusion has been reported. The 6 “Ps” associated with compartment syndrome are: Pain out of proportion based on exam, paresthesia, palmar, paralysis, paresthesia, and pain. Fasciotomy may be necessary to relieve pressure and restore extremity perfusion. Although debated, measured compartment pressure of 30 mm Hg is generally accepted indication for lower extremity fasciotomy. (See also Section I: “Rhabdomyolysis.”)

REFERENCE

CONDYLOMATA LATA
DESCRIPTION
Also called flat condyloma, these moist or mucous papules are found in the skin folds of the groins. They secrete serous fluid and can be covered by a layer of epidemial cells. They represent the hematogenous spread of syphilis. (See also Section I: “Syphilis.”) (Image 49)

TREATMENT
• Single dose of penicillin G (benzyl penicillin)
• 2.4 million units IM-PR
• IM olsalazine, 1,000 mg/d for 10 days OR
• Oral tetracycline 500 mg QID for 14 days OR
• Oral dapsone 100 mg BID for 14 days

REFERENCE

CONGENITAL ADRENAL HYPERPLASIA (CAH)
DESCRIPTION
The adrenal cortex secretes 2 components, DHEA and androstenedione, that require androgenic effects, each...

**CONTACT DERMATITIS, UROLOGIC CONSIDERATIONS**

characterized by a deficiency or total lack of a particular enzyme involved in the biosynthesis of cortisol steroids, particularly cortisol. Steroidogenesis is then channelled into other pathways, leading to increased production of androgens, which accounts for virilization. Simultaneously, the deficiency of cortisol results in increased secretion of ACTH, resulting in adrenal hyperplasia. Certain enzyme defects may also impair aldosterone secretion, adding salt-wasting to the virilizing syndrome. The most commonly recognized forms are 21-hydroxylase deficiency (21-OH deficiency), 11-hydroxylase deficiency (11-OH deficiency), 18-hydroxylase deficiency (18-OH deficiency), and 17α-hydroxylase deficiency. (See also Section I: “Dysfunctional Elimination Syndrome.”)

**REFERENCES**

**CONGENITAL NEPHROSIS/NEPHROTIC SYNDROME**

**DESCRIPTION** Congenital nephrotic syndrome is a rare condition affecting children in the 1st months of life. Familial incidence occurs as an autosomal recessive mode of inheritance. This disease is seen most frequently in Finland (1:8,000 live births). Clinical manifestations include wide anterior and posterior fontanelles, generalized edema, abdominal distension, anasarca, and malnutrition. Characteristic lab findings include proteinuria, hypoalbuminemia, hypercholesterolemia, and hyperlipidemia. Long-term survival is dependent on transplantation. Treatment of bowel dysfunction alone can resolve chronic constipation and fecal incontinence in some children. It is important to rule out neurologic and bowel disease as causes of constipation before making the diagnosis of functional constipation. (See also Section II: “Dysfunctional Elimination Syndrome.”)

**TREATMENT**

- Diet changes
- Diuretics, stool softeners
- Toilet schedules

**REFERENCES**

**CONTACT DERMATITIS, UROLOGIC CONSIDERATIONS**

**DESCRIPTION** Contact dermatitis is caused by an external irritant or allergen and the patient complains of itching and burning or itching. The findings include inflammation, scaling, and crust formation. Extreme reactions can result in blisters and vesicles. Allergic agents typically induce dermatitis after repeated contact with the skin.
CONTRAST-INDUCED NEPHROPATHY (CIN)

DESCRIPTION
An acute and usually reversible form of acute kidney injury following the administration of radiocontrast media. Onset is often 12–24 hr after the contrast study, with renal recovery typically beginning within 3–5 days. It is nonoliguric. The process behaves as a clinical acute tubular necrosis (ATN) with decreased GFR and increased FENa. Risk factors include renal insufficiency (Cr > 1.5 mg/dl), GFR < 60 ml/min, diabetes, heart failure, dehydration, and multiple contrast studies within 72 hr. The mechanisms of the injury are thought to be renal vasoconstriction with resulting tubular hypoxemia and direct cytotoxic effects of contrast material. Older agents are hyperosmolar and toxic, and carry a higher risk of nephrotoxicity, whereas newer agents are iso-osmolar and nonionic and have a lower risk of renal injury. (See also Section II: “Contrast-Induced Nephropathy” and Section VII: “Nephrotoxic Drug-Induced Nephropathy.”)

TREATMENT
Preventative— Avoid contrast material if possible; consider alternative imaging modalities such as ultrasound or CT/MRI without contrast. Avoid dehydration and NSAIDs, as both increase renal vasoconstriction.

Patch testing of uninvolved skin to common sensitizing agents for the genital skin is performed. Severe reactions (rarely) may require debridement and grafting.

Contrast-induced nephropathy diagnosed following a procedure should be managed as ATN:
– Do not biopsy kidney. Injury is usually transient.
– Carefully control fluid and electrolyte balance; hemodialysis is usually unnecessary.
– Avoid further nephrotoxic insults and/or medications.

REFERENCE

CORTICAL NECROSIS, ACUTE (RENAL CORTICAL NECROSIS)

DESCRIPTION
Acute cortical necrosis is a rare form of acute renal failure (ARF) characterized by necrosis of the cortex with sparing of the medulla. It is thought to be the result of selective arterial spasm of the cortical vasculature with continued perfusion of the renal medulla via the medullary arterioles. Pathologically, necrosis of the glomeruli, tubules, and arterioles occurs. A cortical rim sign can be seen on contrast-enhanced CT scan, indicating spared perfusion of the renal capsule. Factors that can predispose a patient to acute cortical necrosis include shock, prerenal azotemia, peritonitis, infection, and toxins. (See also Section II: “Renal Failure.”)

REFERENCE

COSTOVERTEBRAL ANGLE TENDERNESS
DESCRIPTION
Costovertebral-angle (CVA) tenderness is a clinical sign elicited by percussion of the CVA and often accompanied by symptoms of flank pain. The CVA is defined by the area formed by the 12th rib and vertebral column. CVA tenderness is a manifestation of renal capsule distension resulting in irritation ofafferent T11–L2 nerve roots. Common causes include pyelonephritis, perirenal abscess, urachitis, acute hydrocephrosis, renal artery occlusion, and renal vein thrombosis. (See also Section I: “Flank Pain.”)

REFERENCE

COUGH STRESS TEST
DESCRIPTION
The cough stress test involves filling the patient’s bladder to at least 300 ml or to subjectively fullness. The patient is then asked to cough as the physician directly visualizes the urethral meatus. The test can be performed with the patient in an upright position or in dorsal lithotomy on an exam table (supine stress test). If urine leakage is noted, the test is positive. The cough stress test has been compared with other more sophisticated testing methods (multichannel urodynamic studies) and has demonstrated good sensitivity and specificity. This test can be used not only as part of the clinician’s physical exam, but as an outcome measure after treatment.

REFERENCE

COWPER DUCT CYST
DESCRIPTION
The Cowper glands are paired perineal structures located in the urogenital diaphragm and are drained by 2–3-cm-long ducts that empty into the bulbous urethra through small, brisk openings. These glands secrete a clear fluid that functions as a lubricant and a coagulation factor for semen during ejaculation and to neutralize traces of acidic urine in the urethra. Abnormalities of these glands and their ducts may result from obstruction and, less frequently, trauma and infection. This diagnosis should be considered in any male presenting with intumescence or obstructive urinary symptoms, particularly when there is a complaint of persistent postvoid dribbling or incontinence. Urography and urodynamic studies are the diagnostic studies of choice.

SYNONYMS
• Cowper glands
• Bulbourethral gland ductextrase

TREATMENT
Endoscopic amputating of the glandulae (translucidae) into the bulbous urethra
CT SCAN, UROLOGIC CONSIDERATIONS

REFERENCE

COWPER GLAND CARCINOMA
DESCRIPTION
Rare tumor that can present with obstructive symptoms, pain with defecation, or constipation. Most have a palpable perineal mass. Microscopically, these appear as adenocarcinomas. However, local necrosis and tissue destruction may prevent exact localization of the site of origin. Combined surgical and radiation therapy has been employed.

REFERENCE

COWPERITIS (INFLAMMATION OF BULBOURETHRAL GLAND)
DESCRIPTION
Normally, the bulbar urethral glands are palpable. A gland lies on each side of the membranous urethra, between the inferior edge of the prostate and the inner border of the anal canal. When they are inflamed, they are irregularly tender and palpable. In chronic inflammation, they enlarge from the size of a pea to that of a hazelnut. With a finger in the rectum, the thumb is held outside on the median raphe of the scrotum just anterior to the anus and the tip of the index finger is placed in the suprapubic area and pressing into the abdomen. Both hands are then pressed downward into the pelvis. It may not always be an effective technique to empty the bladder, since the external urethral sphincter may contract during the maneuver.

SYNONYM
Manual compression of bladder

REFERENCE

CREMASTERIC REFLEX
DESCRIPTION
The cremasteric reflex is a useful sign in the evaluation of the acute scrotum. The classic presentation of testicular torsion is sudden onset of severe unilateral pain, often associated with nausea or vomiting. The normal reflex consists of cremasteric contraction with elevation of the testis, elicited by stroking the pubocanal upper medial thigh. The innervation is carried via the genito-inguinal nerve. The reflex was previously reported to be absent in 100% of cases of testicular torsion; however, there have been reported cases of preserved cremasteric reflex in the setting of testicular torsion. As such, the presence or absence of this reflex should not influence the decision to perform a scrotal exploration when there is a clinical suspicion of torsion.

REFERENCE

CRIRIFORM CLEAR CELL HYPERPLASIA OF THE PROSTATE
DESCRIPTION
This condition may be misdiagnosed as cribriform prostate carcinoma, but anticytokeratin staining of the basal cell layer distinguishes the 2 lesions. Also, hyperplasic cells lack cytologic atypia, which is in contrast to carcinoma. The natural history is unknown; the lesion is usually found in the central area of the gland.

REFERENCE

CRYPTOCOCCUS, GENITOURINARY
DESCRIPTION
An opportunistic fungal infection, Cryptococcal meningitis thrives in areas inhabited by birds. A pulmonary site is most common primary infection site, but immunocompromised patients can develop disseminated disease (AIDS, transplant). Adrenal insufficiency has been reported, but the most common sites of GV involvement are the prostate and kidney. The prostate may be a reservoir in patients with AIDS. Epididymitis and perine involvement have also been reported. GU involvement is considered a manifestation of systemic disease. (See also Section I: “Fungal Infections, Genitourinary.”)

TREATMENT
• Systemic antifungal therapy with fl uconazole or itraconazole, fluconazole, fluconazole, or combination of drugs
• Surgical drainage of large abscesses may be considered.

REFERENCE

CRITICAL-INDUCED ACUTE KIDNEY INJURY (ACUTE RENAL FAILURE)
DESCRIPTION
Acute tubular necrosis of crystals poorly soluble in human urine can lead to AKI. This form of AKI most commonly occurs as a result of acute uric acid nephropathy (tumor lysis syndrome) or following the administration of other drugs, such as aminoglycosides, methotrexate, indinavir, lamivudine, efavirenz, etoposide, and high doses of Vitamin C. The presentation is usually asymptomatic and detected by worsening serum creatinine, although renal colic symptoms may be present. Severe volume depletion (preserved state) is the most important predisposing factor to crystal induced AKI when patients are receiving the above medications. Likewise, the 1st step in treatment is correction of volume status, usually with isotonic saline and loop diuretics in order to wash out crystals. (See also Section I: “Acute Kidney Injury, Adult (Renal Failure, Acute”).)

CULP-DEWEERD PYELOPLASTY
DESCRIPTION
A pyeloplasty technique best suited for management of UPI obstruction in the setting of a long segment of obstructed proximal ureter. A Culp incision is carried out over the anterior and medial aspect of the renal pelvis and continued down across a point beyond the UPI obstruction. The apex of the flap is brought down to the apex of the ureterostomy, where a 5-0 chromic suture is placed. The posterior and anterior anastomoses are completed with interrupted 5-0 chromic sutures.

REFERENCE

CUNNINGHAM CLAMP
DESCRIPTION
A clamp device designed to compress the urethra and prevent urinary incontinence in males only. The clamp is usually placed on the midshaft of the penis and requires the user to have manual dexterity, intact penile skin, good cognition, and a sensate penis and bladder. The clamp comes in small, medium, and large sizes. It is inexpensive and the most commonly used clamp device. Other types are commercially available based on this urethral compression concept.

REFERENCE

CYCLOPHOSPHAMIDE (CYTOXAN) TOXICITY
DESCRIPTION
Cyclophosphamide (sometimes referred to historically by the former brand name Cytoxan) is an alkylating chemotherapeutic agent used to treat many blood cell cancers and as an effective immunosuppressant for other diseases such as rheumatoid arthritis. Common side effects include bone marrow suppression, alopecia, leukopenia, and nausea. However, Cytoxan has unique toxicities, including the development of hemorrhagic cystitis and secondary cancers such as uterine carcinoma of the bladder and leukemia. Acrolein, a metabolite of Cytoxan, is the major cause of acute hemorrhagic cystitis (and thought to be the cause of long-term increased risk of uterine carcinoma in patients treated with Cytoxan). Hemorrhagic cystitis can be prevented by administering Mesna at the time of Cytoxan readministration. Mesna binds the toxic metabolites acrolein. (See also Section 1: “Cystitis, Hemorrhagic (Infectious, Noninfectious, Radiation”), Section II: “Chemotherapy Toxicity, Urologic Considerations.”)

TREATMENT
- Mesna can be given either PO or IV, and its routine concurrent use is recommended in the treatment of patients receiving cyclophosphamide and ifosfamide. It should be discontinued when hemorrhagic cystitis is present as it can prevent the development of the cystitis but is ineffective in treating active bleeding.
- Hydration: Forced saline diuresis and the medication Mesna were similar in preventing the incidence of cyclophosphamide-induced hemorrhagic cystitis in some studies. – ASCO recommends that patients receiving high-dose cyclophosphamide in the setting of hematopoietic cell transplantation receive Mesna in conjunction with saline diuresis.

REFERENCES

CYSTADENOCACARINOMA, GENITOURINARY
DESCRIPTION
Comrnonly seen in other organ systems, such as the ovaries, pancreas, appendix, and thyroid. In the GU system, cystadenocarcinoma has been reported in testes, prostate, paratesticular structures, and kidney. Grossly, multicystic, multicystic masses are noted. Microscopically, cuboidal to columnar epithelium is seen lining the cysts. These cells can secrete various mucinous substances. Exfoliative cells will demonstrate multilayering of epithelium, nuclear atypia, and invasion of surrounding stroma. It is treated by primary surgical resection.

REFERENCE

CYSTADENOCAARINOMA, GENITOURINARY
DESCRIPTION
A benign cystic epithelial-lined mass that has been described in the kidney, seminal vesicle, prostate, and epididymis (most common GU tract site). It is often described as a papillary cystadenoma and represents benign epithelial hyperplasia. It usually causes very few symptoms. Ultrasound can be bilateral, and 2/3 may be associated with Von Hippel-Lindau syndrome. Grossly, the lesion appears cystic. Microscopically, it demonstrates cells with dense, vacuolated cytoplasm arranged in glandular or papillary structures. It appears as a cystic-to-solid mass at the head of the epididymis on ultrasound. Treatment is observation or radical orchidectomy, if the diagnosis is in doubt.

REFERENCE

CYSTADENOCAARINOMA, RETROPERITONEAL
DESCRIPTION
Primary retroperitoneal tumors of mucinous type are extremely rare. They can be sub-divided into cystadenoma (a benign cystic epithelial-lined mass), borderline, and cystadenocarcinoma (multicystic cystic masses with multilayer epithelium, nuclear atypia, and invasion of surrounding stroma). Prompt diagnosis is important, as the majority of cystadenocarcinomas are malignant. Presenting symptoms can be vague. Given their malignant nature, they should be considered in the differential diagnosis of chronic abdominal pain. Cross-sectional abdominal imaging is the primary diagnostic modality. Radical resection remains the treatment of choice. (See also Section 1: “Retroperitoneal Mass, Fluid and Cysts.”)

REFERENCE

CYSTIN C
DESCRIPTION
A 13 kDa nonglycosylated endogenous protein found in all nucleated cells that has a constant rate of production unaffected by diet. Its clearance is not affected by renal tubular function. It is currently not clearly available, but it likely replaces serum creatinine as the standard test in GFR measurement.

REFERENCE

CYSTIC FIBROSIS, UROLOGIC CONSIDERATIONS
DESCRIPTION
In this genetic disease affecting 1 in 2,000 Caucasian births, defective chloride transport across the epithelium occurs. This leads to complications involving the pancreas, liver, salivary glands, and lungs. Unusual findings include bilateral absence of the vas deferens, leading to infertility. Abnormal development of the mesonephric system, inguinal hernias, hydropsalpinx, and undescended testes are also seen. Risk of testicular cancer may be increased. (See also Section 1: “Vas Deferens, Congenital Absence.”)
CYSTITIS, RADIATION

DESCRIPTION Radiation cystitis can be caused during the course of pelvic radiation treatment. Patients may experience urgency, frequency, dysuria, and urination of small volumes. Bladder spasm may also be present. This can

CYSTITIS, EOSINOPHILIC

DESCRIPTION A rare and severe form of allergic cystitis. Symptoms include hematuria, urgency, dysuria, and suprapubic discomfort. Urine analysis may show eosinophilia. Cytoscopic findings may reveal raised plaques or ulcers that mimic CIS or invasive bladder cancer. Bladder biopsy revealing eosinophilic infiltrate is pathognomonic. Potential causes include food or drug allergies (including methotrexate, anisakis acid, and thiotepa). Parasitic infections should also be considered as etiologies. Some confusion in the literature exists between this entity and granulomatous cystitis. Conservative medical management with oral antibiotics, antihistamines, and steroids with an allergy evaluation are required. See also Section II: “Cystitis Granulomatous.”

TREATMENT
• Conservative medical management with oral antibiotics, antihistamines, and steroids
• A full allergy evaluation is required

 CYSTITIS, EOSINOPHILIC

REFERENCES

CYSTITIS, POLYPOID AND PAPILLARY

DESCRIPTION These benign lesions may appear cystoscopically as papillary urothelial neoplasms and are a reaction to urothelial injury. Polypoid cystitis becomes papillary cystitis when the condition becomes chronic. Similar lesions occur throughout the urothelial tract and are referred to as polypoid urothelium, polypoid urothelial cystitis. They are seen in the urethra, ureters, and renal pelvis, respectively, and are the most diagnostically similar lesions. Clinical settings for this diagnosis include evaluation of gross hematuria, bladder and/or urethral stones, prostatic cancer with radiation therapy, history of urethral carcinoma treatment, long-term urinary stents, and colorectal fibrosis. Proper diagnosis relies on low-power microscopic identification of the reactive process with an infiltrated background that is edematous or densely fibrous with predominantly simple, nonatrophic, broad-based fronds of relatively normal-thickness urothelium. If the tissue is examined at higher power, some foci may appear to resemble a urothelial neoplasm. Treatment is directed at the inciting cause.

CYSTITIS, RADIATION

DESCRIPTION Radiation cystitis can be caused during the course of pelvic radiation treatment. Patients may experience urgency, frequency, dysuria, and urination of small volumes. Bladder spasm may also be present. This can

CYSTITIS, GRANULOMATOUS

DESCRIPTION Granulomatous cystitis (sometimes called eosinophilic cystitis) or eosinophilic granulomatous cystitis in the literature, thus leading to some confusion of this entity is a rare ale cystitis of the bladder of granulomatous cystitis in patients who often have a significant allergic history. In women, other forms of irritable cystitis, such as interstitial cystitis, TB, and bladder neoplasms. The cause is unknown, but believed to be various antigens that form immune complexes and stimulate eosinophilic infiltration. It can be seen in some patients. The use of intravesical BCG for bladder cancer as a tissue factor, edematous bladder with histopathological plaques, ulcers, and submucosal hemorrhage. Microscopy reveals fibrosis and inflammatory cells with extensive eosinophilic infiltration of bladder wall. Patients present with frequency, dysuria, and hematuria.

TREATMENT
• Condition is usually benign with self-limited course
• Optimal management is unclear; usually NSAIDs, steroids, and antihistamines

REFERENCES
Progress to hemorrhagic cystitis with diffuse bladder mucosal inflammation and hemorrhage. The initial response of the bladder to radiation exposure results in an edematous and friable bladder. There can be extensive endarteritis with friable mucosa. Long-term radiation cystitis may present with delayed bleeding remote from the exposure to radiation (6 mo–20 yr after). The hallmark is intractability that bleeds easily, however when bladder bleeding occurs long-term, bladder cancer should be ruled out. Life-threatening hemorrhage is a possible consequence of radiation-induced hemorrhagic cystitis. Amiodarone has shown potential in prevention of GI and acute bladder toxicity from radiation. (See Section I: "Cystitis, Hemorrhagic Infectious, Noninfectious, Radiation.")

**TREATMENT**

- Establish source with evacuation of clots is the initial intervention along with the connection of any coagulopathy if present should be the initial conservative management based on the clinical presentation.
- Endoscopic electrocautery or laser ablation of bleeding site
- Intravesical album
- Hyperbaric oxygen (100% oxygen at higher than atmospheric pressure) 60–95% effective
- Perfusion polypeptide 100 mg 3 times a day, conjugated estrogens
- Intravesical instillation of formalin (32% solution of formaldehyde) in the absence of reflux
- Refractory life-threatening hemorrhage may require more aggressive intervention: Using selective embolization of the vessel or internal iliac arteries, diversion of the urinary stream (nephrostomy tubes, ileal conduit) with or without cystectomy (Image 4: Quantiﬁcation, POP-Q).

**REFERENCES**

---

**Cystitis, Viral**

**DESCRIPTION**

Viruses are increasingly recognized as the cause of lower UTIs—especially hemorrhagic cystitis—among immunocompromised patients. Viral cystitis is usually self-limited.

**TREATMENT**

In immunocompromised patients, the use of antiviral agents (cidofovir, valaciclovir, ribavirin) administered by PO, IV, or intravesical routes is recommended.

**REFERENCE**

**Cystocele Grading: Baden-Walker, Pelvic Organ Prolapse Quantification (POP-Q)**

**DESCRIPTION**

The grading and evaluation of cystoceles have evolved from the Baden-Walker grading scale to the current Pelvic Organ Prolapse Quantification (POP-Q) system. Although the 2 staging systems are widely used in clinical practice, POP-Q is more commonly used in the literature. The classic Baden-Walker grading system was 1st described in 1968. POP-Q was later developed in 1996. Both staging systems base the degree of prolapse on the leading edge during a Valsalva maneuver. (See also Section II: Pelvic Grading ([Image 3: Pelvic Grading: Pelvic Organ Prolapse Classification]).)

**Baden-Walker Grading**

- Grade 0: No prolapse
- Grade 1: Leading edge descends halfway from the hymen.
- Grade 2: Leading edge descends to the hymen.
- Grade 3: Leading edge descends past the hymen.
- Grade 4: Procidentia or vault erosion

**POP-Q Staging**

- Stage 0: No prolapse
- Stage I: Leading edge is > 1 cm above the hymen
- Stage II: Leading edge is between 1 cm above and 1 cm below the hymen.
- Stage III: Leading edge is < 1 cm below the hymen but less than total vaginal length – 2 cm (TVL; total vaginal length) – 2 cm
- Stage IV: Leading edge is below hymen by more than TVL – 2 cm

---

**Cystoscopy Processing**

**DESCRIPTION**

Cystoscopic evaluations are a major component of urological practice used for both diagnostic and therapeutic procedures. The American Urologic Association (AUA) and Society of Urologic Nurses and Associates (SUNA) have issued joint recommendations for reproducible cystoscopes. The key findings are summarized here:

- Cystoscopes are “semi-critical” devices requiring high-level disinfection and sterilization between patients. High-level disinfection differs from sterilization; high-level disinfection does not kill large numbers of bacterial spores; sterilization is the complete destruction of all microbial life.

- Bacterial cystitis is usually self-limited.
DEEP VENOUS THROMBOEMBOLISM (DVT) PROPHYLAXIS: AUA GUIDELINES

DAYTIME FREQUENCY SYNDROME (POLLAKIURIA)

DESCRIPTION The complaint of frequent daytime voiding (pollakiuria (from the Greek pollakis, meaning often) is a fairly common pediatric complaint. Other terms to describe the condition include extraordinary daytime urinary frequency, and in early literature, slam urinary tract infection. It is seen somewhat more often in boys between 4 and 10 yr. In children the differential includes UTI, diabetes mellitus, detrusor instability (DI), obstruction, and bladder detrusor instability. If no cause can be determined simple behavioral regimens have demonstrated effectiveness including reassuring the parents and child and waiting for the condition to self-resolve. Reducing dietary intake of oxalate-rich beverages such as tea and acidic juices such as apple in children who consume large amounts of them, along with liberal intake of water, have been proposed as ancillary approaches. The child needs to learn to ignore the urges and postpone voiding with some type of reward system.

DEEP VENOUS THROMBOEMBOLISM (DVT) PROPHYLAXIS: AUA GUIDELINES

DESCRIPTION Venous thromboembolism (DVT) or PE can occur in 1–5% of patients after major urologic surgery. Risk factors include advanced age, prior venous thromboembolism, cancer, hypercoagulable states, immobilization, obesity, smoking, pelvic dissection, lithotomy position, and many others. Bleeding risk must be weighed against the benefits of prophylaxis. Risk of PE can be divided into low, moderate, and high risk. Reduced risk decreases with additional risk factors.

Low risk: Minor surgery, <40 yo, no additional risk factors

Moderate risk: Risk surgery with additional risk factors or patients 40–60 yo with no additional risk factors

High risk: Patients >60 yo or OR patients 40–60 yo with additional risk factors

RECOMMENDATIONS

• Transurethral or low-risk procedures: Early and continuous prophylaxis with additional risk factors

• Moderate risk: Heparin 5,000 U SQ q8h start post op OR Enoxaparin 40 mg SQ daily (if CrCL <30 mL/min 30 mg)

• High risk: Heparin 5,000 U SQ q8h start post op OR Enoxaparin 40 mg SQ daily (if CrCL <30 mL/min 30 mg)

• Very high risk: Patients with multiple risk factors

Cytokinin Staining

DESCRIPTION Commonly used in prostate cancer diagnosis (to differentiate PIN from basal cell hyperplasia or distinguish various forms of acinar proliferations that are not cancer on needle biopsy) (Michel, which indicates basal cell-specific CK, is commonly used. If basal cell staining is present, this helps to rule out carcinoma. It is also used to examine lymph node or peritumoral tissues for prostate cancer and may increase the accuracy of lymph node staging. It has shown promise in breast cancer staging, where up to 1/3 of patients have unsuspected micrometastases: Correlation to preoperative serum prostate-specific antigen. This section is utilized. Other effects include voiding dysfunction by invading peripheral nerves. CMV cytolsis has been reported to occur in AIDS, and it is 1 of the 10/18 infections that can cause fatal immunosuppression. CMV has been associated with peripheral renal vein thrombosis, and it can be a cause of virally induced hemorrhagic cystitis. Ganciclovir has been effective in transplant patients. (See also Section I: “Immunocompromised Patients, Urologic Considerations.”)

REFERENCES

Cytology, Prostate

DESCRIPTION Exam of cells, usually obtained by fine-needle aspiration (PNA), for the detection of malignancy. Characteristics that can be determined include cellularity, ploidy status, cell cycle distribution, and cytologic grade. Its advantages over standard pathologic techniques involve ease and rapidity of technique, when used in combination with flow cytometry, it seems to increase accuracy. The findings must be read by an experienced cytotechnologist to ensure reliability. The use of this technique has declined greatly in favor of needle biopsy. (See also Section II: “Needle-Needle Aspiration, Prostate.”)

REFERENCES

Cytology, Urinary

DESCRIPTION Microscopic exam of the urine, usually performed for the detection of malignant cells during follow-up of urothelial carcinoma. Criteria for malignancy include increased cytolytic-to-nuclear ratio, eccentric nucleus, nuclear pleomorphism and irregularity, hyperchromasia, chromatin clumping, nuclear crowding and overlapping, prominent nucleoli, mitotic figures, lack of cytolytic vacuolization, and loss of cell cohesion. Highly accurate (90%) in high-grade carcinoma and CIS but less than (50–50%) accurate in low-grade bladder cancer. It is also useful in detecting unsuspected residual tumor and may predict future tumor recurrence after transurethral resection (image 8).

REFERENCES

In the office setting, high level disinfection (using glutaraldehyde or another chemical disinfectant) should include precleaning, leak testing, cleaning, disinfection, rinsing, and drying.

Glutaraldehyde “soak times” are 20–45 min. With no precleaning a 45-min glutaraldehyde soak is required. A 20-min soak is adequate if recommended reprosection steps are followed prior to immersion in glutaraldehyde.

One chemical disinfectant (ortho-phthalaldehyde [OPA]) has been associated with anaphylaxis in cystoscopes.

One chemical disinfectant (ortho-phthalaldehyde [OPA]) has been associated with anaphylaxis in cystoscopes.
DEHYDROEPIANDROSTERONE (DHEA) AND DHEA SULFATE (DHEA-S) BLOOD TEST

REFERENCE

DEHYDROEPIANDROSTERONE (DHEA) AND DHEA SULFATE (DHEA-S) BLOOD TEST

DESCRIPTION
Because they are produced in the adrenal cortex, serum levels of DHEA and the sulfated form (DHEA-S) reflect adrenal gland function. Normal values range differ by age and sex. Common clinical reasons to measure these levels include female virilism, premature puberty, Cushing, and adrenal cancer. DHEA-S is the major form in serum. Generally, blood levels of both forms decrease in the aging male, and replacement has been linked with improved outcomes in Alzheimer disease and systemic lupus.

TREATMENT
• Androgenic medication
• β-Blocker medication
• Behavioral modifications
• Address underlying cause of dementia

REFERENCE

DENT DISEASE

DESCRIPTION
Characterized by hypercalciuria, nephrocalcinosis, kidney stones, renal failure, and rickets. It is a disorder of the proximal tubule with an X-linked recessive inheritance. Symptomatic disease is almost exclusively confined to males. Typical childhood presentation is polyuria, microscopic hematuria, asymptomatic proteinuria, or renal failure. Treatment is focused on reducing the hypercalciuria. (See Section II: “Hypercalciuria [Absorptive, Renal, and Resorptive].”)

REFERENCE

DENYS-DRASH SYNDROME (DDS), UROLOGIC CONSIDERATIONS

DESCRIPTION
Also called Drash syndrome; a rare disorder consisting of congenital nephropathy, Wilms tumor, and DDS (male pseudohemaphroditism) resulting from WT1 gene mutations on chromosome 11p13. Patients develop hypertension, end stage renal disease (ESRD), and gonadoblastomas in their dysgenetic gonads.

TREATMENT
• Early prophylactic bilateral nephrectomy
• Gonadectomy
• Chemotherapy based on National Wilms Tumor protocol
• Renal transplantation after 2 yr of disease free on dialysis

REFERENCE

DERMATITIS HERPETIFORMIS

DESCRIPTION
Dermatitis herpetiformis (also called Duhring disease) is an autoimmune blistering disorder associated with gluten sensitivity, and autoimmune and lymphoproliferative disorders. It is characterized by grouped erosions, urticarial plaques, and papules with vesicles, and has been described on the external genitalia. It is extremely pruritic, and the vesicles are often excoriated to erosions by the time of physical exam. Diagnosis is made by the presence of IgA deposits in the upper papillary dermis seen on direct immunofluorescence of a skin biopsy specimen. The mainstay of treatment are dapsone and a gluten-free diet.

REFERENCE

DERMATOPHYTE, EXTERNAL GENITALIA

DESCRIPTION
Dermatophytes are the most common type of fungi that cause skin and nail infections, and they can involve the external genitalia. The irritation is often caused by the dermatophyte, Trichophyton rubrum. They typically present in those adults with excessive perspiration as a major risk factor. Skin manifestations include red, raised, sharply defined, itchy lesions in the groin that may extend to the buttocks, inner thighs, and external genitalia. Warm weather and tight clothing encourage fungal growth. Also consider treating tinea pedis (“athlete’s foot”), as this is often the original site of the offending organism.

SYNONYMS
• Tinea cruris
• Ringworm
• Jock itch

TREATMENT
• Weight loss, improved personal hygiene; tarsol, cornstomach, or other desiccant powders to keep the area dry
• Topical antifungals (powders, ointments, lotions, solutions) such as terbinafine (Lamisil), clotrimazole (Lotrimin, Mycelex), econazole (Spectazole), ciclopirox (Lopex)

REFERENCE

DERMOMA CYST, TESTICULAR

DESCRIPTION
Cysts (epidermoid cyst) are benign intratesticular neoplasms and a variant of cystic teratomas that contain ectodermic derivatives. Patients present with a palpable, firm, nontender testicular mass. Case reports indicate occurrence over a wide range of ages, from 5–85 yr. Dermoid cysts are typically well encapsulated and unilocular. They occur more often in the right testicle (upper/lower pole) and are usually treated with focal excision or excision.

REFERENCE

DERMOMID CYST, TESTICULAR

DESCRIPTION

They occur more often in the right testicle (upper/lower pole) and are usually treated with focal excision or excision.
DESMOPLASTIC SMALL ROUND CELL TUMOR

DESCRIPTION

Rare, usually very aggressive neuroectodermal tumor that typically presents in the abdominal cavity but may involve the GU system. Those patients with GU involvement tend to be younger men. Histologically, irregular nests of small round cells surrounded by fibrous connective tissue are seen. Immunohistochemical studies reveal both epithelial and nonepithelial origins. Associated with a unique translocation between chromosomes 11 and 22, that involves EWSR1 and WT1 genes. Prognosis is poorly poor, largely due to majority of patients presenting with metastatic disease. Surgical resection and multidisciplinary chemotherapy have been employed with poor success.

REFERENCE

DE TONI-FANCONI-DEBRE SYNDROME

DESCRIPTION

Syndrome of multiple defects of tubular function, characterized by aminoaciduria, phagohistolysis, glycosuria, osteodystrophia, and renal tubular acidosis. The proximal renal tubule is shortened and replaced by a thin tubular structure, constituting the swan-neck deformity.

TREATMENT

• Replacement of cation defects (especially potassium)
• Correction of acidosis with bicarbonate or citrate
• Replacement of phosphate loss with isosonic neutral phosphate solution
• Encouragement of liberal calcium intake with added vitamin D

REFERENCE

DETRUSOR OVERACTIVITY

DESCRIPTION

Evolutory or unihabitited contraction of the detrusor muscle (as seen with multichannel urodynamics) in the absence of a neurologic cause. According to the Incontinence Society definition: DO is an anaerobic observation characterized by involuntary detrusor contraction during the filling phase which may be spontaneous or provoked. Clinically, DO usually presents as urinary urgency, with or without urinary frequency, urgency incontinence. (See also Section I: “Overactive Bladder.”) The etiology of DO can be either neurogenic or idiopathic.

SYNONYM

Overactive bladder

TREATMENT

• Behavioral modification: Fluid restriction, avoidance of bladder irritant
• Pelvic floor exercises
• Anticholinergic/antimuscarinic therapy
• Alpha-adrenergic receptor antagonist therapy
• Botulinum toxin type A

• Sacral neuromodulation
• Posterior tibial nerve stimulation
• Surgical treatments: Resection/cystotomy, augmentation cystoplasty

REFERENCES

DEXAMETHASONE SUPPRESSION TEST

DESCRIPTION

The dexamethasone suppression test is designed to diagnose and differentiate among the various types of Cushing syndrome and other hypercortisolism states. Results indicate of Cushing disease involve no change in cortisol on low-dose dexamethasone but inhibition of cortisol on high-dose dexamethasone. If the cortisol levels are unchanged from both low- and high-dose dexamethasone, then a cortisol-secreting adenocortical tumor is suspected or an ectopic ACTH source. Occasionally, other conditions (such as major depression, alcoholism, stress, obesity, kidney failure, pregnancy, or uncontrolled diabetes) may interfere with cortisol levels.

The low-dose test depends on the fact that only minimal change in cortisol is usually present in Cushing disease, whereas patients with Cushing disease will show no change in cortisol on low-dose dexamethasone but marked suppression on high-dose dexamethasone. Typically, the test is performed in the morning on an empty stomach after fasting. A single oral dose of dexamethasone, 0.5 mg, is administered 1 h before the cortisol sample is obtained on day 1. This represents the low-dose dexamethasone test.

REFERENCES

DIET CRISIS

DESCRIPTION

The most severe manifestation of nephropathies, originally described by Leof in 1864. Classically described as catabolic candal pain, nausea, chills, septicemia, oliguria, and transient hematuria or proteinuria. Nephropathy secondary to vascular obstruction of the ureter is the postulated cause. Physical exam reveals an enlarged, tender kidney.

TREATMENT

• Manual reduction of the ptotic kidney was initially used
• Nephropathy has been used for nephropathies and was 1 of the most commonly performed operations of the early 20th century, uncommon procedure today

REFERENCE

DIMERCAPTOSUCCINIC ACID (DMSA) RENAL SCAN

DESCRIPTION

DMSA allows the visualization of detailed renal cortical anatomy because it accumulates in the kidney at the proximal renal tubules and is slowly excreted in the urine. DMSA renal imaging is the most sensitive radiologic study used to detect pyelonephritic changes and scarring in the kidneys.

REFERENCE

DIURETIC RENOGRAM

DESCRIPTION

A noninvasive nuclear medicine study that provides functional information regarding upper urinary tract obstruction (sometimes referred to as “Latex renogram”). This test is most commonly utilized to determine obstruction in the setting of hypertension. A tubular agent is preferred, therefore IODI is widely used for its high extraction fraction, rapid parenchymal transit, low radiation absorbed dose, and excellent imaging properties. The recommended dose of 15 microCurie (200 MBq) is sufficient for children. Use of higher doses of 30 microCurie (100 MBq) is not recommended. The test is performed in the morning after a 3–4 h fast. A diuretic agent, typically furosemide, is given and the renal scan is performed in the supine position. The renal scan is repeated at 20 min intervals for up to 1 h. The renal scan is repeated at 20 min intervals for up to 1 h. The renal scan is repeated at 20 min intervals for up to 1 h. The renal scan is repeated at 20 min intervals for up to 1 h.

A normal anatomic variant of the left kidney secondary to molding by the spleen. It is usually mistaken for tumors on IVP or intravenous pyelography. Other imaging, such as CT, MRI, or renal US can be used to rule out a tumor. Appropriately named after the domesticated camel. (See also Section II: “Renal Pseudotumor.”)

REFERENCE

Dysfunctional voiding is characterized by an intermittent and/or fluctuating flow rate due to incoordinate intermittent contractions of the periurethral striated muscle during voiding in neurologically normal individuals. Although dysfunctional voiding is not a very specific term, it is preferred to terms such as “nonneurogenic neurogenic bladder.” Other terms such as “dysfunctional detrusor sphincter dyssynergia,” or “dysfunctional neurologically normal voiding dysfunction,” may be preferable. However, the term dysfunctional voiding is very well established. The condition occurs most frequently in children. While it is felt that pelvic floor contractions are responsible, it is possible that the intraurethral striated muscle may be important. It was originally described by Hinman and Bauman in 1973 after a review of similar reported cases. Upper tract damage can occur. Diagnosis is through videourodynamics. (See also Section II: “Hinman Syndrome (Hinman–Allen Syndrome).”)

Other imaging, such as CT, MRI, or renal US can be used to rule out a tumor. Appropriately named after the domesticated camel. (See also Section II: “Renal Pseudotumor.”)

REFERENCE

A complaint of loss of urine that occurs after completion of voiding, thought to be caused by retained urine in the urethra distal to the sphincter in men and retained urine in the vagina or vesical vault distal in women. In men, it is a complaint associated clinically with BPH, following radical prostatectomy and stricture disease. Recent data suggest it may be a surrogate for median lobe hypertrophy in BPH.

REFERENCE

A normal anatomic variant of the left kidney consisting of a bulge of normal tissue that mimics a tumor. Dromedary humps arise from the superosteal aspect of the left kidney secondary to molding by the spleen. It is usually mistaken for tumors on IVP or intravenous pyelography. Other imaging, such as CT, MRI, or renal US can be used to rule out a tumor. Appropriately named after the domesticated camel. (See also Section II: “Renal Pseudotumor.”)

---

**EICHOCINOCOCUS, RENAL**

**DESCRIPTION** Renal hydatid disease is a parasitic tapeworm infestation that results in renal cysts that occupy space and cause local mass symptoms. This infection is caused by the larval stage of the cestode *Echinococcus granulosus*, whose definitive host is the dog and the principal intermediate is the sheep. Common symptoms include flank pain, hematuria, and local pressure. The diagnosis of renal echinococcus requires a high index of suspicion and despite a complete clinical history, serologic, radiologic, and urine data, the yield is only 50%. Radiographic findings include a calcified, oval or linear cystic mass in the kidney. During cyst excision, great care must be taken to not spill or rupture the cyst, because the liberated parasites could be spread and cause anaphylaxis. (See also Section II: “Hydatid Cysts.”)

**SYNONYMS**

- Cystic hydatid disease
- Hydatid cyst

**TREATMENT**

- Surgical excision of intact cyst, with care not to spill or rupture the cyst
- Medical treatment is reserved for noncurable cases (albendazole 400 mg twice daily for 4–6 mo)

**EDEMA, LOWER EXTREMITY, UROLOGIC CONSIDERATIONS**

**DESCRIPTION** Edema of the lower extremity can occur iatrogenic, physiologic, or psychogenic in nature. It may result in cardiopulmonary problems. Uterine and vaginal edema may be observed in patients undergoing urologic surgery, they should be euthyroid prior to their intervention. Thyroidectomy or thyroid storm can present with fever, laryngospasm, confusion, and cardiovascular collapse. Hyponatremia is generally associated with an increased sensitivity to medications such as anesthetic agents and narcotics; its severe form can be associated with myoclonic dystonia, opsoclonus, electrocerebral imbalance, and decreased gastrointestinal motility.

**DESCRIPTION** The presence of ecchymosis in the flank region (Gray-Turner sign) is a physical sign of retroperitoneal bleeding. Common associations may include renal trauma, ruptured abdominal aortic aneurysm, and acute pancreatitis.

**REFERENCE**

---

**EDWARD SYNDROME**

**DESCRIPTION** Also known as trisomy 18, it is the 2nd most common autosomal trisomy after Down syndrome. Characterized by structural heart defects, kidney malformations, esophageal atresia, nephroblastoma, facio-cutaneous naevi, and genital hypoplasia among other signs. High incidence of urogenital abnormalities noted with adrenal kidney in about 20% of cases; hydronephrosis, hypospadias, and inguinal hernia are also common. Up to 90% of patients die within the 1st yr of life, usually secondary to cardiopulmonary problems. Urinary and vaginal abnormalities are common in females.

**REFERENCE**

---

**EJACULATION, PAINFUL**

**DESCRIPTION** So called “female ejaculation” is the expulsion of fluid by females during or before sexual orgasm. The prevalence varies between 10–54%, whereas the amount of fluid ranges from 1–900 mL. There are natural sexual responses but may also represent symptoms of urinary incontinence. The term encompasses various phenomena with different underlying pathophysiologic mechanisms noted below:

- **Vaginal lubrication**: Vaginal fluid is forced out by the contractions of perineal muscles.
- **Ejaculation**: Either organic expulsion of semen or well-synchronized expulsion of the “female prostate” (known as Skene glands), or organic expulsion of diluted urine (squirtng/gushing), or the combination of both.
- **Cystic incontinence**: Leakage of urine that occurs during penetrations or orgasm. Usually associated with stress or urge urinary incontinence.
- **Penetration incontinence**: occurs more frequently and is usually caused by SD. Urodynamic diagnoses of detrusor overactivity (DO) and SUI are observed in organic incontinence. (See also Section I: “Incontinence, Urinary, Adult Female”, Section II: “Cystic Incontinence [Cystal leakage/Irritative Incontinence Incontinence]”)

**REFERENCE**

---

**EJACULATION, PAINFUL**

**DESCRIPTION** The incidence of pain associated with or immediately after ejaculation is 1–8%. Can be urogenetic, physiologic, or psychogenic in nature. Ejaculatory or postorgasmic pain is believed to arise from interference with the coordination of the muscles of the pelvic floor and male genita that are responsible for semen transport during ejaculation. (See also Section II: “Disparuresia.”)
EJACULATORY ANHEDONIA

CAUSES

- Prostatitis
- BPH
- Ejaculatory duct obstruction (EDO) by calculi
- Postoperative (prostatectomy)
- Antidepressants
- Pelvic neuropathy

TREATMENT

- α-Adrenergic inhibitors
- Rule out and treat EDO
- Pelvic nerve injection with bupivacaine/trimethaphan
- Pelvic nerve release

REFERENCE

EJACULATORY ANHEDONIA

DESCRIPTION

A rare condition, affecting males predominantly, in which ejaculation occurs without an accompanying sense of erotic pleasure. Most common causes are psychogenic in origin or related to ESHI antidepressant usage.

REFERENCE

EJACULATORY DUCT OBSTRUCTION (EDO)

DESCRIPTION

EDO is found in 1–5% of infertile men, producing azoospermia with low-volume, acidic ejaculate that has no fructose. Obstruction of the ejaculatory ducts prevents the emission of sperm and seminal fluid into the posterior urethra during ejaculation. Congenital causes include utricular, mullerian and Wolff duct cysts, ejaculatory duct stenosis, or atresia. Acquired causes include infection, calculus, trauma, or prior instrumentation. Physical exam is usually normal, with the occasional palpable malleable mass or dilated seminal vesicles. Semen analysis shows low-volume, acidic, frank, absent fructose, and failure to coagulate. Transrectal ultrasonography (TRUS) demonstrates a cystic, miliary structure within the prostate, with dilated seminal vesicles. When TRUS is equivocal, additional tests include TRUS-guided seminal vesicle aspiration (demonstrates abundant spermatozoa) or aspiration biopsy. (See also Section II: "Ejaculatory dysfunction.")

TREATMENT

Through transrectal resection of ejaculatory duct, in which the ejaculatory duct is unroofed by transrectal resection at the level of the verumontanum, until efflux from the ducts is seen.

REFERENCE

ELECTROEJACULATION

DESCRIPTION

Procedure for obtaining sperm for ARTs in patients who cannot ejaculate on their own, such as SCI patients, typically used after failure of vibratory perineal stimulation. General anesthesia is used, except in cases of complete spinal cord compromise. A transrectal probe is positioned with electrodes against the anterior rectal wall. Electrical stimulation causes ejaculation and erection in ~85% of patients. Retrosigmoidoscopy is performed before and after the procedure to rule out renal injury. Blood pressure monitoring is essential during the procedure for patients who may have autonomic hyperreflexia.

REFERENCE

ELECTROMYOGRAPHY, EXTERNAL SPHINCTER

DESCRIPTION

Generally, electromyography is the measurement of bioelectric potentials generated by the depolarization of muscle. During voiding, the activity of the external sphincter can be monitored by transperineal needle electrodes or surface electrodes. During filling, there should be maximum decrease in activity, which will reach maximum near capacity. During voiding, there should be a persistent cessation of sphincter activity. At the end of the voiding phase, sphincter activity returns to baseline. To assess external sphincter activity, the patient may be asked to interrupt voiding in the middle of the stream, at which point there should be an abrupt increase in sphincter activity sufficient to stop the flow. Abnormal EMG patterns may be detected in detrusor sphincter dyssynergia and dysfunctional voiding. EMG monitoring may also be used during biofeedback therapy for dysfunctional voiding.

REFERENCE

ELEJALDE SYNDROME

DESCRIPTION

Also known as ano-congenital perineal dysplasia, this exceedingly rare autosomal recessive syndrome is characterized by crouzon- and fibroblast hyperplasia in organs such as skin, larynx, and pancreas. High birth weight, craniofacial disproportion, polyphalantergy, sphenoid abnormalities, hypertrophic nephrosis, and renal cysts are also common features.

REFERENCE

ELEPHANTIASIS, SCROTUM (ELEPHANTIASIS SCRITTI)

DESCRIPTION

Also called rhinophyma scroti, this is the end result of a progressive lymphatic obstruction in which the scrotum and penis can become massively enlarged. Usually associated with filariasis, which is uncommon in the United States. Differential includes filariasis and other infectious causes; malignancy obstructing lymphatics; surgical therapy that has altered lymphatic drainage; and idiopathic, such as Milroy disease. (See also Section I: "Edema, External Genitalis (lymphedema, Pene-Scrotal Edema)", Section II: "Filariasis, Urologic Considerations." and Image O1)

TREATMENT

- Drugs therapy for any infective etiology
- Surgery for retraction of redundant scrotum with flap coverage of testes

REFERENCE

ENCOPRESIS, UROLOGIC CONSIDERATIONS

DESCRIPTION

Children who are inconsistent of stool, even with minor fecal soiling, usually have significant constipation. Occult pathology of the bowel and/or urogenital system may be ruled out as a possible cause. Encopresis usually is helpful in identifying bowel problems when the parents of a child are not aware of the child's stool habits. Children with encopresis and constipation have a higher risk of UTI and urinary incontinence. Successful treatment of functional constipation will usually resolve encopresis and associated urinary tract problems. The term “total incontinence” is sometime used as the preferred term over encopresis or soiling. (See also Section I: “Dysfunctional Elimination Syndromes.”)

TREATMENT

- Diet changes
- Laxatives, stool softeners
- Toilet schedules

REFERENCE

ENCRUPTED CYSTITIS AND PYELITIS

DESCRIPTION

Exacerbatory urinary-tract condition of the bladder and pelvic urogenital system characterized by inflammation with calcium deposits (struvite and apatite calculi). Commonly, the presence of alkaline urine, infection by urea-splitting Corynebacterium urealyticum (formerly called Corynebacterium group D2), a multiple antibiotic-resistant urea-splitting bacterium, is the most frequently incriminated agent, and recent history of a urologic procedure in a immunocompromised host (eg, renal transplant) is found. Clinical manifestations of encrusted cystitis are often febrile, dysuria, and gross hematuria. Encrusted pyelitis may have lumbar pain in addition to symptoms of encrusted cystitis. Imaging on US and CT may reveal calcific encrustations with thick-walled edematous bladder and/or pelvisceral cavity. Calculations within appear on plain abdominal radiographs unless associated with staghorn calculus. The endoscopic appearance is of calciﬁed within plaques adherent to a severely inflamed and ulcerated mucosa. Bacteriologic diagnosis of Corynebacterium group D2 requires culture for 48–72 hr at 37°C on media enriched with 5% carbon dioxide (CO2) or sheep blood agar.

REFERENCE

This rare mucinous analog of Wilson W, Taubert KA, Gewitz M, et al. Prevention of Antimicrobial prophylaxis for REFERENCE.

López-Medrano F, García-Bravo M, Morales JM, et al. REFERENCE. are much more likely to cause infectious endocarditis that bacteremia resulting from random daily activities exceed the benefit. The AHA guidelines concluded every patient is imperative in preventing this challenging complication.

ENCROCUTED URETERAL STENT DESCRIPTION Indwelling ureteral stents are routinely employed for the prevention and treatment of ureteral obstruction secondary to intrinsic, extrinsic, and idiopathic causes such as urethrakinks, strictures, and/or malignancy. Indwelling tube users affect rate of encrustation: Consensus is that stents should not remain in place longer than 3–6 mo (high degree of variation according to different series). Reported risk factors include urethral tract infections (urease-producing microorganisms) and pregnancy. Site and degree of encrustation will guide the approach appropriate use in single or multiple, for this purpose several grading systems and management algorithms have been proposed. Good communication between physician and patient in preventing this challenging complication.

ENDOCRIDS (SBE) PROPHYLAXIS, UROLOGIC CONSIDERATIONS DESCRIPTION Antimicrobial prophylaxis for urology procedures: policy to prevent infectious endocarditis is no longer recommended by the American Heart Association: the risk of adverse events exceed the benefit. The AHA guidelines concluded that bacteria resulting from random daily activities are much more likely to cause infectious endocarditis than bacteria associated with GU procedures.

ENDOCRIVICOSIS, BLADDER DESCRIPTION This rare micronodular analog of endometriosis histologically demonstrates glandular lesions characterized by a prominent endometrioid-type epithelium that may involve the urinary bladder in women of reproductive age. Typically are observed in the posterior wall of the bladder or the dome. Lack of awareness may lead to confusion with a adenocarcinoma, particularly of urothelial origin given its location. Because of this, these are presumed to have an underlying malignancy and are treated surgically. Patients usually present with irritative voiding symptoms and pelvic pain. Transurethral resection of partial hysterectomy is curative, and close follow-up is recommended.

ENDOMETRIOSIS, GENITOURINARY DESCRIPTION Endometriosis is a condition in which endometrial tissue is found outside the uterus. Most common sites in the GU system are the Bladder and distal 3rd of rectum. Other symptoms are variable and may include dysmenorrhea and pelvic pain with or without urinary symptoms of gross hematuria, flank pain, frequency, or urgency. Urinary symptoms may or may not be exacerbated with menstruation, and the classic symptom of “cyclical hematua” is uncommon. Diagnosis is through TVPCT-urography and urine analysis, laparoscopy to inspect the pelvis and obtain tissue biopsy, or cystoscopy or ureteroscopy to evaluate hematuria and dilated biopsy.

TREATMENT

• Hormonal therapy with oral contraceptives, danazol, or GnRH agonists
• Surgery when medical treatment fails
• Partial cystectomy, ureterolysis, ureteric reimplantation, or uretal lancing may be performed

EPICA-2 (EARLY PROSTATE CANCER ANTIGEN) DESCRIPTION A nuclear matrix protein (NMP) that showed promise as a new serum-based biomarker of prostate cancer, which was postulated to have better sensitivity and specificity than PSA. However, at the request of the authors (Leman et al., Urology, 2012; 79(2):490–499), the original article was retracted as there were inconsistencies in validating their data collection.

EPIDERIDYMIS, METASTASIS TO DESCRIPTION This is a benign tumor that accounts for 1/3 of all primary epidermoid tumors. Epidermoid cysts are seen in up to 2% of patients with von Hippel-Lindau disease and are often bilateral with this syndrome. They have a cystic appearance on ultrasound and can be up to 6 cm. Cut surface is gray-brown and contain fluid. The histologic appearance is that of divided tubules with a single or double layer of cuboidal or low columnar epithelium. Rarely can be mistaken for metastatic RCC. Papillary cystadenomas and benign and generally asymptomatic and no treatment is required. (See also Section I: “Scrotum and Testicle, SCROTAL Mass” and “Spermatocele”; Section II: “Epididymal Cysts.”)

EPIDEMIDYAL CYST, TESTICLE DESCRIPTION Epidermoid cysts account for ~1% of all testicular tumors. Producing keratinizing, squamous cell-lined cysts supported by fibrous tissue, these cysts are considered special cases of teratoma since only a single germinal layer and not the required 2 layers is represented. Benign in behavior, cystic US is supportive of the diagnosis but not usually definitive. (See also Section I: “Scrotum and Testicle, Mass.”)

TREATMENT

• Impalpable orchidectomy
• Some advocate organ-preservation surgery if the diagnosis is definitively proven by frozen section.

EPIDMYAL CYSTADENOMA/ PAPILLARY CYSTADENOMA DESCRIPTION This is a benign tumor that accounts for 1/3 of all primary epidermoid tumors. Epidermoid cystadenomas are seen in up to 2% of patients with von Hippel-Lindau disease and are often bilateral with this syndrome. They have a cystic appearance on ultrasound and can be up to 6 cm. Cut surface is gray-brown and contain fluid. The histologic appearance is that of divided tubules with a single or double layer of cuboidal or low columnar epithelium. Rarely can be mistaken for metastatic RCC. Papillary cystadenomas and benign and generally asymptomatic and no treatment is required. (See also Section I: “Scrotum and Testicle, Mass,” “Spermatocele,” and “von Hippel-Lindau Disease/Tumours” and Section II: “Epidermoid Cysts.”)

EPIDMYLIS, METASTASIS TO DESCRIPTION Employed rare, with primary sites reported to include colon, stomach, kidney, prostate, carcinoid, and pancreatic tumors. Prognosis is related to that of the primary disease. Patients can present with pain and swelling or an incidental finding on orchidectomy for prostate cancer. 4 mechanisms for spread have been proposed, including direct extension, retrograde venous extension, orthograde lymphatic extension, and arterial embolism.

REFERENCE
EPIDIDYMS, OBSTRUCTION

REFERENCE

EPIDIDYMS, OBSTRUCTION

DESCRIPTION
A cause of obstructive azoospermia. Most common cause is vasectomy, which results in a fixed obstruction and elevated vesiculogram pressures resulting in the dilation of the epididymal tubules. Other causes include trauma, congenital malformation of the vas and epididymis, infection, inflammatory damage to the epididymis, and idiopathic. Epididymospermatocele is the treatment of choice. (See also Section 1: “Infertility, Urologic Considerations” and “Vas Defects, Congenital Abnormalities,” Section A: “Azoospermia.”)

REFERENCE

EPITHELOID HEMANGIOMA, PENIS AND SCROTUM

DESCRIPTION
Rare vascular lesion, typically arising on the head and distal extremities, whose pathogenesis is not fully understood. Genital involvement has rarely been reported. These lesions do not recur following excision and no metastasis has been reported. Macroscopically, the lesions are described as an inflammatory red to brown nodule. Microscopically, the lesions are characterized by endothelial cells arranged in nests surrounded by immature vessels and eosinophilic cell stroma. Differential diagnosis includes epithelioid hemangioma, epithelioid hemangioendothelioma, epithelioid hemangioendothelioma, Kimura’s disease, and bacillary angiomatosis. Treatment is local excision.

REFERENCE

ECTRICAL DYSFUNCTION INVENTORY OF TREATMENT SURVEY (EDITS)

DESCRIPTION
A validated satisfaction questionnaire for both patient (11 items) and partner (15 items) based on their subjective evaluation of the treatment for ED. Few of the disease-specific instruments used to assess ED address sexual dysfunction-related quality of life, psychosocial impact, and satisfaction. EDITS attempts to address both patient and partner satisfaction with ED treatment, in addition to sexual dysfunction.

REFERENCE

ERECTILE DYSFUNCTION SCORE (EHS) FOR ED

DESCRIPTION
The EHS was developed as a single-item, patient-reported outcome to quantify erection hardness data. It is easy to use and highly responsive to treatment. Psychometric analysis supports its use as a simple, valid, reliable, and responsive tool for the assessment of erection hardness in clinical research.

REFERENCE

ERYSPHELAS, EXTERNAL GENITALIA

DESCRIPTION
Superficial bacterial infection of the dermis, with sudden demarcated lymphatic involvement. The infection affects extremes of age, and the most common site of involvement is the face. Typically heralded by pain, superficial erythema, and plaque-like edema with a sharply defined margin to normal skin, it may often be described as a “pool of orange appearance. The clinician must differentiate erysipelas from cellulitis and furunculonecrosis (exclusion of this diagnosis is a priority in all cutaneous infections of the external genitalia). It is usually caused by Group A hemolytic streptococcus (S. pyogenes), or rarely S. aurous.

TREATMENT
- Mild infection: PO penicillin, macrolides, or clindamycin
- Severe infection: Parenteral penicillin or vancomycin

REFERENCE

ERYTHEMA MULTIFORME (EM), EXTERNAL GENITALIA

DESCRIPTION
EM is a common acquired blistering skin condition that affects all age groups, ethnicities, and sexes. EM minor is a mild subtype that usually is confined to skin and oral involvement. EM major (Stevens–Johnson syndrome) affects skin and often other mucocutaneous-lined surfaces including the eyes, oral cavity, and external genitalia. The hallmark of EM is a target lesion, a circular erythematous macular lesion resembling a bull’s-eye. Commonly occurring on the hands. Painful rash is characteristic, and macules, papules, urticaria, vesicles, bullae, pustules, or pachydermae are characteristic. In EM major, large tracts of skin and oral mucosa may be denuded, along with conjunctivitis, and GI and upper GI involvement. HSV is the most common cause but virtually any infectious agent or drug can cause EM. Main differential is toxic epidermal necrolysis.

TREATMENT
- EM minor: Warm compress with topical astringent, topical aciclovir (for HSV-related EM)

REFERENCE

ERYTHRASMA

DESCRIPTION
Superficial, asymptomatic cutaneous infection by the diphtheroid Corynebacterium minutissimum. Physical exam reveals a sharply demarcated, round to oval plaques with scales in the intertriginous or interdigital regions. Wood’s lamp examination with a Wood’s light will reveal a characteristic yellow-orange fluorescence. Historically, only the stratum corneum is affected, with all other layers normal. More common in tropical climates. Despite there being no consensus on the ideal treatment for the condition, usually it consists of topical or oral antibiotic therapy for 14 days (erythromycin or tetracycline). Recent evidence suggests single-dose clindamycin may be an alternative regimen.

REFERENCE
RARE ENTITY REPRESENTING 3–5% OF EGG
K, Khoury A. The exstrophy-epispadias complex. REFERENCE
EEC is a rare congenital urogenital anomaly with a spectrum of complexity ranging from epispadias and bladder exstrophy to cloacal exstrophy. Incidence of bladder exstrophy is between 1 in 10,000 and 1 in 50,000 live births, with a male predominance. The risk of recurrence is in a family is 1 in 100. The condition is believed to be due to failure of the cloacal membrane to be reinforced by growth of mesoderm, therefore preventing the midline separation of mesenchymal tissues and lower abdominal wall development. The cloacal membrane ruptures prematurely and, depending on the stage of development during which the rupture occurs, a variant of the complex will result. Most anomalies relate to defects of the abdominal wall, bladder, genitalia, pelvic bones, rectum, and anus. See also Section I. “Epispadias” and “Exstrophy, Bladder (Classic Exstrophy).”

TREATMENT
• Immediate at birth: Prevent irritation/trauma to exposed urorectal surface (eg, “Swan wrap”)
• Surgical reconstruction must consider appearance of lower abdomen and genitalia, pelvic bone reconstruction, continence, and subsequent sexual function
• Staged reconstruction: Early bladder, abdominal wall, and posterior urothelial closure, with osteotomy. Epispadias repair begins at 2–3 mo. Reconstruction of continent bladder neck and urethral channel, usually at age 4–5 yr
• Single-stage reconstruction

REFERENCE

EXTRAGONADAL GERM CELL TUMORS (EGCT)
DESCRIPTION Rare entity representing 3–5% of all GCT. There is a clinical association with Klinefelter syndrome, and testicular ultrasound is necessary to exclude primary tumor in the testes (or ovaries in females). Primary EGCT are usually midline in decreasing frequency: Medulloblastoma, retroperitoneal, pineal/suprasellar region, and the sacrococcygeal region. All tumor types are reported, with von Hippel-Linderheim being most common. They can present with widespread dissemination, and advanced metastasis with few symptoms. Transformation to sarcoma or carcinoma has been reported with chemotherapy resistance common in these cases. 1 or both testicular tumor markers (pHCG or AFP) are elevated in >85% of cases of EGCT. Management of EGCT parallels that of metastatic testicular GCT, however EGCT have a worse prognosis.

TREATMENT
• Surgical excision, F feasible
• Chemotherapy, irradiation, or combination based on histology and in general follows testicular cancer regimens.

REFERENCE

EXTRAMAMMARY PAGET DISEASE, UROLOGIC CONSIDERATIONS
DESCRIPTION A rare cutaneous malignancy arising from ducts of apocrine-gland bearing skin. Most often involving the anogenital region, more commonly seen in the elderly and women. The condition presents with a well-circumscribed erythematous scaly patch, similar in appearance to mammary Paget disease. There is a 10% association with underlying metastatic GI (most commonly bladder) or GI (most common colon) malignancy. Differential diagnoses include SCC in situ of malignant melanoma.

TREATMENT
• Surgical excision with wide margin, Mohs microsurgical excision, or radiation
• Screen for occult GI and GI malignancy

REFERENCE

EXTRAMEDULLARY HEMATOPOIESIS, RENAL
DESCRIPTION This is a reactive process in response to the failure of hematopoiesis in the bone marrow. It commonly occurs in organs such as the liver, spleen, and kidney. It commonly occurs in the presence of myelofibrosis (most common), chronic myeloproliferative disorder, polycythemia vera, and essential thrombocytosis. Considered a cause of renal parenchymal, a renal mass in association with any of these disorders should raise the possibility of an extramedullary hematopoiesis. Biopsy confirmation is usually required.

REFERENCE

FABRY DISEASE/SYNDROME
DESCRIPTION Fabry disease is a rare X-linked disorder characterized by the deficient activity of the lysosomal enzyme α-galactosidase A. Progressive accumulation of the substrate (globotriaosylceramide GL-3) leads to progressive organ failure and premature death. Findings consist of multiple cutaneous lesions (angokeratoma corpus circumflexum), neural specification, and progressive renal insufficiency. Symptoms of severe burning pain in the extremities usually begin in the 1st decade, and can cause fibrile episodes. Cardiovascular effects include coronary artery disease and congestive heart failure. Renal failure leads to anemia and hypertension in the 3rd–5th decades.

TREATMENT
• Enzyme replacement therapy with agalsidase-beta

REFERENCE

FAMILIAL TESTOTOXICOSIS
DESCRIPTION Cause of testicular pain, infertility inherited as an autosomal dominant pattern. Markedly elevated levels of testosterone with normal LH secretion are noted, but sleep-associated LH pulses are absent. Patients typically present with family history and testicular enlargement around ages 3–4. Diagnosis is a lack of testosterone response to HCG administration, despite a measurable increase in LH. Hypertension of Leydig cells is noted by biopsy. Ketoticoticotic, antiandrogens, aromatase inhibitors, and/or medroxyprogesterone acetate have been used in different combinations with success.

REFERENCE

FANCONI SYNDROME
DESCRIPTION An acquired or inherited disorder characterized by abnormalities of renal proximal tubular function, including hyperuricemia, phosphaturia, aminoaciduria, and bicarbonaturic wasting. The aminoaciduria is generalized, and deficits in uric acid, water, potassium, and sodium absorption can also occur. The basic abnormality is unknown. Acquired disease is caused by deacetylase or inhibited tetrahydrobiopterin, renal transplantation, multiple myeloma, amyloidosis, introduction with heavy metals or other chemotherapeutic agents, and vitamin D deficiency, inherited form (usually seen with other disorders) presents in infancy with proximal tubular acidosis, hypophosphatemic rickets, hypokalemia, polyuria, and polydipsia. In nephropathic form, failure to thrive and growth retardation are common, with progressive renal failure. Diagnosed by demonstrating the abnormalities of renal function.

REFERENCE

FANCONI SYNDROME
DESCRIPTION An acquired or inherited disorder characterized by abnormalities of renal proximal tubular function, including hyperuricemia, phosphaturia, aminoaciduria, and bicarbonaturic wasting. The aminoaciduria is generalized, and deficits in uric acid, water, potassium, and sodium absorption can also occur. The basic abnormality is unknown. Acquired disease is caused by deacetylase or inhibited tetrahydrobiopterin, renal transplantation, multiple myeloma, amyloidosis, introduction with heavy metals or other chemotherapeutic agents, and vitamin D deficiency, inherited form (usually seen with other disorders) presents in infancy with proximal tubular acidosis, hypophosphatemic rickets, hypokalemia, polyuria, and polydipsia. In nephropathic form, failure to thrive and growth retardation are common, with progressive renal failure. Diagnosed by demonstrating the abnormalities of renal function.

REFERENCE
FATTY CASTS

TREATMENT
• Stomach bicarbonate for acidosis
• Renal transplantation has been successful

REFERENCES

FATTY CASTS
DESCRIPTION
Fatty casts contain fat globules embedded within tubular epithelial casts. Polished light microscopy may reveal "Mallory's cross" appearance if cholesterol is present. These are most commonly associated with nephrotic syndrome, but occasionally seen also after long-bone fractures, and classically seen in fat embolus syndrome.

REFERENCE

FECAL INCONTINENCE, UROLOGIC CONSIDERATIONS
DESCRIPTION
Numerous studies have identified a relationship between urinary symptoms and fecal incontinence. In the Nurses’ Health Study of over 64,000 women ages 63–87 yr, the prevalence of dual urinary and fecal incontinence was 7% (fecal incontinence alone was 4% and urinary incontinence alone was 38%). Risk factors for dual incontinence in women included: age >80 yr; depression; neurologic disorders; functional limitations; multiparity; and childbirth of a heavy newborn (>9.5 lb). As compared with white race, black race was associated with a decreased risk of dual incontinence. Men and women with overactive bladder (OAB) are significantly more likely to report having chronic constipation or fecal incontinence compared with those without OAB. Causes of OAB include vaginal delivery with anal sphincter damage, surgical trauma, diabetes mellitus, decreased rectal compliance (ulcerative proctitis and radiation proctitis), impaired rectal sensation (diabetes, HIV, dementia, malignancies, myelopathy, SCI), fecal impaction, medications, mood disorders, and diabetes mellitus. Fecal incontinence can be caused by any condition that impairs the recto-anal inhibitory reflex or the puborectalis reflex. Fecal incontinence can be acute, transient, or chronic. While incontinence itself is not a serious medical condition, it is a significant source of anxiety and distress for both individuals and their caregivers.

REFERENCE

FECALULIA
DESCRIPTION
The presence of fecal matter passed per urethra, suggestive of a fistulous communication between the urinary and intestinal tracts. Ectopic ureters include a pathologic process such as Crohn’s disease, diverticulitis, and cancer, or iatrogenic causes such as perineal surgery, radiation, or trauma. Initial evaluation should include cross-sectional imaging in the form of CT (modality of choice) or MRI to help delineate the location of the fistulous tract.

REFERENCE

FEMALE HYPOACTIVE SEXUAL DESIRE DISORDER
DESCRIPTION
Female sexual dysfunction has been defined in the DSM-IV manual as persistently or occasionally deficient or absent sexual fantasies and desire for sexual activity that causes marked distress or interpersonal dysfunction. Prevalence ranges from 39–43% in recent studies. The operational definition of desirosexual is currently being reviewed. The DSM V is scheduled for release in May 2013.

CAUSES
• Impaired: Hypothalamic/hippocampal dysfunction, menopause, chronic or antidepressive pills
• Musculoskeletal: Hypo- or hyperactivity of pelvic floor
• Neurologic: Spinal cord injury (SCI), other nervous system disorders (MS, CVA)
• Psychogenic: Relationship problems, poor body image/esteem, mood disorders
• Vasomotoric: Post blood flow, pelvic atherosclerosis, trauma
• Iatrogenic: Medication use (antidepressants, esp. SSRIs)

TREATMENT
• Education: Desire-arousal-orgasm axis, emotional intimacy, anatomic explanation
• Lifestyle modification: Stress management, adequate rest, regular exercise
• Pharmacology: Topical vaginal estrogens improve vaginal lubrication and atrophy, but have shown no effect on sexual desire. Testosterone (300 g/d transdermally) has shown benefit in postmenopausal women, but remains unapproved by the FDA. Phosphodiesterase inhibitors have not shown improvement for women with diminished desire.

REFERENCE

FEMALE SEX FUNCTION INDEX (FSFI)
DESCRIPTION
The FSFI is a validated questionnaire to assess female sexual function. It was developed for the specific purpose of assessing domains of sexual functioning (e.g., desire, sexual arousal, lubrication, orgasm, satisfaction, pain) in clinical practice. It was not designed for use as a diagnostic instrument and should not be used as a subscale for a complete sex history in clinical evaluation. The FSFI was validated in 2 groups of women, including subjects with sexual arousal disorder (determined by history) and age-matched controls. The instrument reliably differentiated these 2 groups in all domains of sexual functioning.

REFERENCE

FEMINIZING GENITOPLASTY
DESCRIPTION
Surgical treatment of a ambiguous genitalia may be indicated in the genetic female with external genitalia of female phenotype. The most common cause of virilization in the female newborn is CAH. Preputial genitoplasty may be performed early in infancy to facilitate gender-appropriate upbringing, or delayed until adolescence when the patient can participate in consent. Extensive counseling of parents of any infant with a disorder of sexual development is critical before considering genitoplasty. Goals of surgery are to create external genitalia with an aesthetic female appearance, and permit sexual function and, if possible, fertility. See also Section II “Disorders of Sexual Development (DDS)”, Section II “Congenital Adrenal Hyperplasia.”

REFERENCE

FERTILE EUNUCH DISEASE/SYNDROME
DESCRIPTION
Syndrome characterized by persistent androgen deficiency or aromatase deficiency caused by luteinizing hormone deficiency or Müllerian inhibitory activity. FSH secretion is present. However, spermatogenesis usually is not entirely blocked in these men, and they are usually fertile. Because there is only relative gonadotropin deficiency and some spermatozoa are present, treatment with LH-like activity (hCG) stimulates Leydig cell testosterone production and aromatizes androgen deficiency, stimulating spermatogenesis sufficient for induction of fertility.

REFERENCE

FIBROEPITHELIAL POLYP, GENITOURINARY
DESCRIPTION
The most common benign uterine tumor, arising from the upper 1/3 of the uterine cervix. These polyps resemble a smooth nodule or may be pedunculated. Histologically, a central fibrous core surrounded by normal or hyperplastic epithelium is seen. Patients present with menorrhagia and hematuria, usually as a young adult. Radiographically, smooth filling defects are seen. Hydrocoeleuroterus can be seen.
seen, as well as ultrasound interrogation. They can recur locally.

TREATMENT
Ultrasound-guided aspiration, open unroofing with prosectorially, or partial unroofing. If the diagnosis cannot be confirmed preoperatively, the lesion should be excised completely. Any doubt about the nature of the lesion should lead to excision. If the diagnosis is confirmed preoperatively, the lesion can be aspirated to relieve symptoms.

REFERENCE

FIBROEPITHELIAL POLYP, PENIS

DESCRIPTION
Fibroepithelial polyp of the penis is a benign tumor found in a small group of men with priapism. Histologically, it is a fibrovascular lesion composed of fibroblasts and elongated, thin-walled vessels. The lesion is usually asymptomatic but can be painful in the case of priapism. Surgical excision is generally recommended.

TREATMENT
Surgical excision is the treatment of choice. Recurrence is rare. The lesion can be managed conservatively in asymptomatic patients with follow-up. Complete excision is necessary for symptomatic patients.

REFERENCE

FIBROHAMSAMTORA OF INFANCY

DESCRIPTION
Common in both sexes, fibrous hamartoma of infancy is a benign tumor that usually appears in the first few months of life. It is composed of a mixture of fibrous and myxoid tissue, and is often associated with skin lesions. The prognosis is favorable, and most lesions regress spontaneously within the first year of life.

REFERENCE

FIBROS PSEUDOTUMOR OF TESTICULAR TISSUE

DESCRIPTION
Fibrosarcoma of the testis is a rare tumor that arises from the germ cell line. It is characterized by the presence of fibrous tissue and is often associated with other testicular abnormalities. The treatment is surgical excision, and the prognosis is generally good with early detection and treatment.

REFERENCE

FISH: URINARY FLUORESCENT IN SITU HYBRIDIZATION (UROVYNSION TEST)

SYNONYMS
Fibrous pseudotumor
Fibroepithelial polyp
Reactive periarteritis

TREATMENT
Surgical excision is usually necessary to confirm diagnosis but local excision can be considered.

REFERENCE

FIDUCIAL MARKERS

DESCRIPTION
External beam radiotherapy is a valuable tool in the treatment of localized prostate cancer. This form of treatment is limited by the difficulty in accurately localizing the prostate gland. The implantation of intraprostatic gold fiducial markers under transrectal ultrasound guidance is a safe outpatient procedure that aids in identifying anatomic structures of interest during radiation treatment (most importantly the prostate-rectal interface). Markers are usually cylindrical and appear as white spots with a hollow bore needle. Surface features prevent migration. The proportionality regimen is similar to that used for ultrasound-guided prostate biopsy. Prophylactic antibiotics are administered, anticoagulant medications withheld 7 days before procedure, and cleansing enemas given to empty the rectal vault. Patients are routinely placed in the left lateral decubitus position. A transrectal ultrasound probe is utilized to calculate prostate volume in the standard fashion. Local anesthesia should be placed bilaterally at the level of the neurovascular bundles. An 18-gauge implant needle is utilized to place fiducial markers into the right base, left base, and apex of the prostate. Standard prostate biopsy discharge instructions are given. Patients then follow up with a radiologist oncologist for pretreatment planning imaging and subsequent radiation therapy (image Q).

REFERENCE

FILARIASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION
Filariasis is transmitted by mosquitos, most commonly Wuchereria bancrofti, endemic to areas of the Caribbean, Venezuela, Colombia, the Guianas, Brazil, Central America, sub-Saharan Africa, North Africa, Turkey, and Asia. Filariasis (Bancroftian, Malayan, and Timorian) is often asymptomatic. The parasite causes symptoms due to inflammation and dysfunction of the lymphatics, where the adult worms develop (liver, head, neck, lymph, and lymphatics). In lymphatic disease, manifestations usually occur 3–7 y after acquisition. Occasionally, moderate lymphopenia, particularly involving the inguinal lymph nodes, occurs. Inflammation of the lymphatics of the extremities and genitalia leads to renegade adenolymphangitis. Epididymitis, orchitis, and hydrocele can also occur, along with fever, chills, and other nonspecific systemic symptoms. Lymphatic dysfunction, with resulting chronic progressive edema of the limbs and genitalia, is relatively infrequent in children. Elephantsiasis can result from fibrosis caused by chronic dysfunction of the lymphatic channels. Chyluria can occur as a manifestation of bancroftian filariasis. Lymphatic filariasis must be diagnosed clinically because serologic tests are not available, and in elephantsiasis the microfilariae may no longer be present. Eosinophilia of 25% frequently occurs in early disease. (See also Section I, “Edema, External Genitalia [Penis] [Testicular Edema].”)

TREATMENT
• Pentastibanazin citrate is the drug of choice. The late obstructive phase of the disease is not affected by chemotherapy.
• Ivermectin, an investigational drug in the United States, is effective against the microfilariae of W. bancrofti, but is unlikely to become the drug of choice for lymphatic filariasis.
• Complex, decongestive physiotherapy may be effective in treating elephantiasis.
• Plastic surgical repair of the genitalia gives variable results.
• Chylioma originating in the bladder responds to fulguration; chylioma originating in the kidney is much more difficult to correct.

REFERENCE

FINE-NEEDLE ASPIRATION (FNA) OF PROSTATE

DESCRIPTION
In the detection of prostatic carcinoma, FNA cytology of the prostate has largely replaced by core needle biopsy of the prostate, as cytology does not allow Gleason grading. However, the detection rates of prostatic carcinoma by either core needle biopsy or FNA appear to be comparable. Largely replaced by core biopsy techniques. (See also Section II, “Urology, Prostate.”)

REFERENCE

FISH: URINARY FLUORESCENT IN SITU HYBRIDIZATION (UROVYNSION TEST)

DESCRIPTION
Cytogenetic studies describe frequent alterations in chromosomes 1, 3, 4, 7, 8, 9, 11, 17, etc., in prostatic carcinoma. FISH allows the study of genetic abnormalities within formalin-fixed cancer cells. UroVysion test is a multitargeted multicolor-FISH assay that stains exfoliated cells from urine specimen with probes for chromosome 3, 7, 17, and Y, and 15, and allows observation of the cells under a fluorescence microscope. Reported sensitivity of UroVysion test is higher for higher-grade tumors (93–97%) and CIS (almost 100%), but with low-grade low-stage tumors (36–57%). Specificity is high (89–96%). A false-positive UroVysion test may predict for future recurrence or simply reflect ultrasound that is not at risk of malignant transformation. A study to detect bladder cancer in a high-risk population showed FISH to be comparable to urine cytology with a higher false-positive rate (Image Q).
**FISTULA, ENTEROVESICAL**

**DESCRIPTION** An abnormal communication between the bowel (such as colo-vesical fistula) and urinary bladder due to various inflammatory and neoplastic causes. Usually presents with fecaluria, pneumaturia, and/or recurrent UTI. Differential diagnosis includes vesicovaginal fistula (VVF), ureterovaginal fistula (UVF), and endometriosis associated with urethrovaginal fistula.

**TREATMENT**
- Surgical excision of fistulous tract and repair
- Conservative management

**REFERENCE**

---

**FISTULA, URETEROARTERIAL**

**DESCRIPTION** May present with microscopic hematuria, intermittent gross hematuria, or torrential bleeding in a patient with associated risk factors. General guideline to reduce the risk of fistula development is the use of the smallest caliber, softest flexible ureteric stent for the shortest possible period. In a stable patient, CT retrograde ureteropyelography, and angiography may be non-specific but aid in planning reconstructive options. Removal of stones and ureteral manipulation should be performed with caution and in a facility where immediate angiographic or surgical intervention is available.

**TREATMENT**
- If stable, early reconstruction of vascular and urinary structures:
  - Vascular occlusion with angiographic stent or embolization; OR
  - Vascular ligation, with or without bypass procedure
  - Ureter reimplantation (urothelial re-implantation, cutaneous ureterostomy, transverse ureteroureterostomy, or urethral Sling with nephrostomy)
  - Endovascular stenting is increasingly used in lieu of open techniques due to the high operative risk and morbidity in patients with ureterocutaneous fistula
- In the actively bleeding patient, immediate surgical intervention or angiographic occlusion

**REFERENCE**

---

**FISTULA, VESICOVAGINAL AND URETEROVAGINAL**

**DESCRIPTION** Vesicovaginal fistula (VVF) is an abnormal communication between the urinary bladder and vagina that may be associated with ureterovaginal fistula (UVF) in 12%. Patients present with urinary incontinence, with prior history of recent pelvic or gynecologic surgery or other causes.

**CAUSES**
- Iatrogenic following obstetric and gynecologic surgery
- Pelvic malignancy
- Pelvic radiation
- Infections: Pelvic and abdominal infections
- Penetrating trauma
- Foreign body

**DIAGNOSIS**
- Pelvic exam
- Cystoscopy with cytology and/or retrograde pyelography
- Contrast imaging (eg, CT urogram with delayed imaging, CT cystography)

**TREATMENT**
- UVF should be managed by reimplantation of ureter. Before undergoing a ureteral reimplantation, a patient with associated risk factors, such as diabetes, hypertension, and obesity, should undergo a pelvic exam to rule out the possibility of a synchronous pelvic malignancy. If a UVF requires primary repair, a multiple-layer closure can be achieved through a transabdominal or transvaginal approach. If diagnosis has been
Baumann DP, Butler CE. Lateral abdominal wall herniation is rare, and the intercostal nerves during incision and closure. Care should be taken to avoid injury to the intercostal nerves during incision and closure. Flank “bulge” is not a true hernia and is believed to be due to laxity of the transversus and internal oblique muscles, caused by injury to the intercostal nerves during incision and closure.

Flank hernia following nephrectomy

DESCRIPTION True flank hernias are rare, and careful palpation may reveal the fascial edges. Obesity, immunocompromised states, and poor nutrition status are risk factors. Frank “bulge” is not a true hernia and is believed to be due to laxity of the transversus and internal oblique abdominal wall muscles, caused by injury to the intercostal nerves, in particular the 11th intercostal, and accumulated in part by unopposed contraction of contralateral musculature. About 15% of patients develop flank bulge after a renal resection.

TREATMENT

• Flank hernia: Generally should be repaired with or without mesh, based on surgeon preference, patient comorbidities, and clinical factors specific to each case. If the patient is asymptomatic or debilitated, a corset can be offered.

• Flank bulge: Repair seldom needed except for cosmetic reasons.

REFERENCES

Fluorescent (Blue Light) Cystoscopy

DESCRIPTION Drugs for fluorescence diagnosis, such as 5-ALA and hexaminolevulinate (Hexvix [EU]; Cypho [US]), are placed intravesically where they preferentially stain multilayer or papillomatous tissue and emit a red fluorescence when excited by visible blue light. Requires specific endoscopic equipment. Fitted with the blue light, camera, and lens with filters. In a meta-analysis, Fluorescent cystoscopy (92.4%) sensitivity was superior to white-light cystoscopy (80.3%). Reports have shown fluorescent cystoscopy to be limited by specificity, which is equivalent to or poorer than white-light cystoscopy. Fluorescent cystoscopy can enhance the diagnosis of patients with positive cytology and no visible lesion on white-light cystoscopy, and for surveillance of high-risk bladder cancers and/or CIS.

REFERENCES

Foley Y-V PyeloPlasty

DESCRIPTION The triangular portion of the Y is incised in the dependent portion of the pelvis, with the apex pointing to the stricture, and a single 2- to 3-cm longitudinal incision is continued from the apex anteriorly down across the stricture to complete the Y configuration. The apex of the triangle flap is then brought down to the lower apex of the ureterostomy and a 5-0 chronic stay suture is placed. Interrupted 5-0 chronic sutures are used to complete the anastomosis. Used for UPU repair.

REFERENCES

Fordyce Spots (Ectopic Sebaceous Glands), Penis

DESCRIPTION Fordyce spots are ectopic sebaceous glands on the lips and buccal and genital mucosa (glans penis and labia minor). Lesions are multicentric and yellowish in color with slightly elevated papules and plaques with sizes ranging from 1–3 mm. Most patients are asymptomatic but some consider receiving treatment for cosmetic reasons since the lesions do not resolve spontaneously. 5-Fluorouracil can be used for ablation.

REFERENCES

Foreign Body, Bladder and Urethra

DESCRIPTION Almost every conceivable foreign body has been inserted into the urinary bladder and urethra, usually for erotic exploration and curiosity, or because of psychiatric disorder or mental retardation. Amnonian paraphilic catfish (Candiru) and leeches have also been reported to enter the urethra while bathing in a river. Symptoms include urinary pain, dysuria, urinary retention, hematuria, frequency, painful voiding, weak stream, and sepsis. (See also Section II: “Bladder filling defects.”)

Fluorescent, Indications, and Technique

DESCRIPTION Formalin (37% formaldehyde) instillation is an option in the management of hemorrhagic cystitis, which is refractory to more conservative measures. A solution of 50 mL of 1% formalin is typically utilized. Instillation must be done in the operating room and usually with general anesthesia, as the procedure may cause pain. Prior to instillation, a cystogram must be performed to rule out vesicoureteral reflux. If reflux is present, then formalin may cause damage to the ureters and intrarenal collecting system. Use of Fogarty catheters to occlude the ureters in the case of reflux is reported. Bladder fibrosis with reduced capacity and increased urinary frequency is a common outcome after formalin instillation. (See also Section II: Cystitis, Hemorrhagic.)

FOSSA NAVICULARIS DIVERTICULUM

DESCRIPTION For described by Guérin (1864), the diverticulum is partially separated from the urethra by a septum. On voiding cystourethrography (VCUG), it can often be seen as a small spherical collection of contrast at the tip of the penis. It is thought to result embryologically from an incomplete breakdown of the wall between the ectoderm and the urothelium being formed by the nephrost girlfriend. It is a common anatomic finding with rare symptoms, including dysuria, gross hematuria, spotting of blood, or hematospermia.

SYNONYMS

• Valve of Guérin

• Dorsal-urethral diverticulum

• Lacuna magna

TREATMENT

If symptomatic, the wall can be divided with tenotomy scissors or under direct vision with a resectoscope.

REFERENCES

FOWLER SYNDROME (PRIMARY DISORDER OF URETHRAL SPHINCTER RELAXATION)

DESCRIPTION

REFERENCE

FOWLER–STEPHENS SYNDROME

DESCRIPTION
This procedure is used in the treatment of high intravesical reflux. It entails ligating the spermatic vessels and ferring on the plexus that the urethra will narrow into the vesical and crometric cataracts. The operation was originally described as a 2-stage procedure in which the ureters are divided, and the left side is brought through the right, and division is completed in the manner, after which the 2 stages are performed to have a slight better success rate (95% for 2 stages vs. 80% for 1 stage). It is commonly performed using laparoscopy.

REFERENCES

FRACTURE RISK ASSOCIATED WITH PROSTATE CANCER AND ANDROGEN DEPRIVATION THERAPY

DESCRIPTION
Androgen deprivation therapy (ADT) treatment of prostate cancer leads to a hypergonadal state. This state predisposes men to osteopenia or osteoporosis with subsequent increased risk of fracture. There is a direct correlation between length of time on ADT and risk of fracture. I study reported that after 5 yr on ADT, the risk of fracture rises nearly 7% compared to controls.

TREATMENT
Men being treated with ADT should be considered for a baseline DXA scan to assess bone mineral density (BMD). Increased weight bearing exercise and cessation of smoking should be encouraged. Also, calcium and vitamin D supplementation can help improve BMD. Daily supplementation of calcium (1,200 mg/d) with vitamin D (400–800 IU/d) is recommended. Systemic therapy (bisphosphonate or denosumab) has been shown to play a role in the prevention of osteoporosis and reduce fracture risk. Denosumab is approved for men on ADT or with osteoporosis 60 mg SC Q 6 mos (Prolia). Bisphosphonates such as zoledronic acid (Reclast) can be given IV 5 mg, alendronate (Fosamax, Fosamax Plus O) and risedronate (Actonel) are given orally weekly. Alternative dosing times are given with the presence of bone metastases to decrease skeletal related events (SREs). Denosumab (Pamab) is given 4 mg SC monthly and zoledronic acid (Zometa) is administered IV 4 mg monthly.

REFERENCES

Fragile X Syndrome

DESCRIPTION
The most common cause of inherited mental retardation. The affected gene encodes a protein known as FMR1, which is required for normal cognitive development, facial dysmorphism and behavioral and microcephaly (MC). The Fragile X syndrome is an autosomal dominant disorder with associated mental retardation.

REFERENCE

FRALEY SYNDROME

DESCRIPTION
A condition in which urinary obstruction of the superior infundibulum might lead to hydronephrosis, bleeding, and intermittent frank pain or infection. Patients who experience symptoms related to urinary obstruction may be admitted to intensive care units. It is important to rule out an underlying cause such as urethral stricture or intussusception before surgery. Treatment is usually surgical, and the cecum of the cecum can be used to correct the obstruction.

TREATMENT
Surgery can provide relief in severely symptomatic patients. Various techniques including infundibulo-infundibulostomy, infundibulopexy, and infundibuloplasty have been reported to be successful in treating symptoms.

REFERENCES

French Catheter Scale

DESCRIPTION
Used to measure the outer diameter of catheters, endoscopes, and other instruments. The diameter in millimeters of the instrument is determined by doubling the French size by 3 (eg, an 18 Fr catheter has a diameter of 6 mm). The system was introduced by a 19th-century French medical instrument manufacturer. (See Section VII: “Catheter Guide.”)

REFERENCE

FREQUENCY, URINARY SYNDROME

DESCRIPTION
Urinary frequency is defined as the patient’s perception that he/she voids too often by day. Although often associated with an overactive bladder and/or bladder outlet obstruction, urinary frequency is 1 of many complaints included in the non-specific, nondiagnostic symptom complex known as lower urinary tract symptoms or LUTS. Frequency is further categorized as 1 of the storage symptoms (experienced during the bladder filling phase or the storage phase of micturition), as opposed to a voiding or postmicturition symptom.

REFERENCE

FREQUENCY-DYSURIA SYNDROME

DESCRIPTION
Occurring in children and women, this is also referred to as the “urethral syndrome.” Patients present with complaints of frequency and dysuria, but evaluation finds no infectious, urologic, functional, or pharmacologic abnormalities. Because this term is so nonspecific, it is not a currently accepted meaningful term for diagnosis or treatment planning. In childhood, hyperactive was theorized in and adults, fastidial organisms were once thought to be the cause. See also Section II “Urinary Syndrome.”

REFERENCE
**FURMAN NUCLEAR GRADING CLASSIFICATION, RENAL CELL CARCINOMA (RCC)**

**DESCRIPTION**
A classification used to grade renal cell carcinoma, based on the concept that nuclear features correlate with survival. This scale consists of 4 grades based on size, contour, and conspicuousness of nucleoli. Large series have confirmed the correlation with survival. Grade 1 is round with minute or absent nucleoli. Grade 2 is slightly irregular nucleoli about 15 μm, with nucleoli visible at 400×. Grade 3 is more irregular nucleoli, 25 μm, with nucleoli visible at 100×. Grade 4 is similar to grade 3, with bizarre features noted. There is a noted correlation between tumor size and Furman grade (image not provided).

**REFERENCE**

**FUNGURIA**

**DESCRIPTION**
Funguria (sometimes called candiduria) refers to fungus in the urine (fungal UTI of the urinary bladder) or kidney. It is a common nosocomial infection. Organisms are typically *C. albicans* and *C. glabrata*. Other organisms can involve the kidney through disseminated infection (eg, *Aspergillus* sp., *Fusarium*, others). Associated predisposing factors include catheters, antibiotics, diabetes mellitus, hospitalization, and immunosuppressed states. Urinary colonization is usually asymptomatic, whereas invasive fungal infection of bladder may have irritative voiding symptoms. Fungal infection of the kidney is often nephroscopic in origin from other sources or the GI tract, fungal renal or perirenal abscesses present similar to pyelonephritis. Infection should be suspected when urine microscopy shows budding fungal hyphae. Positive fungal urine culture demands investigation. (See Section I: “Fungal Infections, the GI tract; fungal renal or perirenal abscesses.”)

**REFERENCE**

**GAMETE INTRAFALLOPIAN TRANSFER (GIFT)**

**DESCRIPTION**
GIFT is similar to IVF but is rarely performed currently with the improved pregnancy rates in IVF. Current indications for GIFT include patients who have no evidence of menstrual or ovulatory abnormalities when they are unable to conceive spontaneously. The treatment involves inserting 2–3 embryos into the fallopian tubes on the day of embryo transfer (if embryo transfer is contraindicated in IVF, the technique may be modified for this indication). It provides a 20–30% pregnancy rate per cycle compared to 10–15% in IVF.

**REFERENCE**

**GANGLIONEUROBLASTOMA, ADRENAL**

**DESCRIPTION**
Extremely rare tumor originating from neural crest cells, this ganglioneuroblastoma exists on a spectrum of diseases between neuroblastoma and ganglioneuroma. It is seen in approximately 1% of children with neuroblastoma and can be solitary or multifocal. Diagnosis is by surgical excision. Treatment is by surgical resection.

**REFERENCE**

**GANGLIONEUROMA, ADRENAL**

**DESCRIPTION**
A tumor originating from neural crest cells, this is the benign counterpart of neuroblastoma. It does not metastasize, but can locally recur after resection and be locally aggressive. It most commonly presents as an abdominal mass. Histologically, the lesion is composed of ganglion cells with abundant cytoplasm and large nuclei. Treatment is by surgical resection.

**REFERENCE**

**GENITAL AROUSAL DISORDER (PERSISTENT)**

**DESCRIPTION**
A condition of spontaneous, intrusive, and frequently unwanted genital arousal associated with urogenital maldevelopment, usually located posterior to the urinary bladder. It is caused by a failure of separation of the urogenital fold of the mesonephric duct that leads to persistence of the Gartner duct, often with cystic dilation. The Gartner duct is associated with pelvic pain, dyspareunia, and resultant infection and related problems.

**REFERENCE**

**GARTNER DUCT CYST**

**DESCRIPTION**
Gartner duct cyst is a rare congenital anomaly associated with urogenital maldevelopment, usually located posterior to the urinary bladder. It is caused by a failure of separation of the urogenital fold of the mesonephric duct that leads to persistence of the Gartner duct, often with cystic dilation. The Gartner duct is associated with pelvic pain, dyspareunia, and related problems. The cyst may be bilateral in cases of heminephrogenesis and is rare in patients with complete renal agenesis or hypoplastic kidney. The treatment is by surgical excision of the cyst and closure of any associated urinary sinus, reconstruction of bladder neck and urethra, and reimplantation of ipsilateral and/or contralateral ureter in a nonfunctioning renal unit and antireflux procedure.

**REFERENCE**

GENITAL ULCERS
DESCRIPTION: Ulcers may be due to multiple causes: Infection, Behçet syndrome, syphilis, malignancy, colitis, and carcinoma in situ are all possible causes. They are most commonly a manifestation of sexually transmitted infections, including chancroid, genital herpes, lymphogranuloma, and primary syphilis. Characteristics of the ulcers associated with sexually transmitted infections are as follows:

- Chancroid: Tender papule that turns painful which has a pustular ulcer underneath; may be single or multiple
- Genital herpes: Multiple painful vesicles
- Lymphogranuloma: A small painless papule or vesicle that ulcerates
- Primary syphilis: Painless, indurated ulcer; usually single

TREATMENT
If a sexually transmitted infection is suspected, empiric antibiotic therapy should be initiated even before confirmatory testing. Chancroid is treated with a single oral dose of azithromycin, or a single intramuscular dose of ceftriaxone, or oral erythromycin for 7 days. Genital herpes is treated with antiviral drugs such as Acyclovir. Lymphogranuloma is usually treated with tetracycline or erythromycin. Primary syphilis is treated with a single dose of intramuscular penicillin G, or a single dose of oral azithromycin in a penicillin-allergic patient. See also Section I: “Sexually Transmitted Infections [STIs].” Sexually Transmitted Diseases (STDs), General."

GENITOURINARY PAIN INDEX (GUPI)
DESCRIPTION: GUPI is a validated 9 question instrument to assess severity of symptoms, in men and women with urolologic pain conditions. The GUPI can differentiate men with chronic prostatitis or interstitial cystitis, those with other symptomatic conditions (diabetes, frequency, chronic cystitis), and those with none of these diagnoses. It can discriminate between women with interstitial cystitis, those with incontinence, and those with none of these diagnoses.

GENITAL PIERCING, UROLOGIC CONSIDERATIONS
DESCRIPTION: Urologists must be familiar with complications from genital piercing. In males, piercings include the penile glans, shaft, urethra, and scrotum. In females, complications include the mons pubis, labia, clitoris, and labial folds. In females are also performed. Complications include:

- Transmission of infectious agent: HIV, Hepatitis B and C, or an STD
- Bleeding
- Cellulitis
- "Cutting-out" or erosion
- Propionibacterium acnes
- Recurrence of condyloma accuminatum
- Urethral fistula
- Hypertrophic scarring, keloid
- Trauma during intercourse: To partner or self

GENITAL SKIN LOSS
DESCRIPTION: Genital skin loss is most commonly iatrogenic, as the result of skin denudement for reconstructing infection by polymicrobial infection—Fournier gangrene. Skin loss can less commonly occur as a result of trauma, usually blunt; however, penetrating trauma can also result in skin loss. Burns can also lead to genital skin loss.

TREATMENT
Reconstruction is the mainstay of treatment. In the case of skin loss due to denudement for infection, the infection should be stable prior to reconstruction being performed. In the case of penile skin loss in an uncircumcised male, a flap using redundant foreskin being performed. In the case of penile skin loss in an uncircumcised male, a flap using redundant foreskin may be harvested to address a proximal defect. Flaps utilizing skin from a penile keratotic plaque may be used in this setting. If a donor site is available, a full thickness skin graft can be used to address both penile and crural skin defects. Vacuum-assisted closure therapy has been effective in early management with skin-grafts (see also Section I: “Scrotum and Testicle, Trauma.”)

REFERENCES

GERM CELL APLASIA (SEER TO CELL ONLY SYNDROME)
DESCRIPTION: Total absence of germ cells within a normal interstitium. Patients present with infertility, and usually with small to normal testes and azoospermic semen specimens. Phenotypically, these patients are normally virilized males. Histologically, Sertoli cells line the seminiferous tubules with a complete absence of germ cells and normal interstitium. Plasma FSH is usually elevated due to the absence of germ cells. Plasma testosterone and LH are normal. Diagnosis is based on an elevated FSH and PRL of the tests. Aplasia may represent the endpoint of various etiologies, resulting in this histologic appearance. Adoption or use of donor sperm is necessary if children are desired.

REFERENCES
Gestational Age Assessment, Urologic Considerations

Description: Gestational age assessment can be derived from 3 clinical methods: (1) physical exam, (2) ultrasound, and (3) history, using the date of the last menstrual period (LMP) to calculate the estimated date of delivery (EDD) or EDD. Clinical assessment of gestational age in a newborn reflects the “menstrual age.” Studies have shown ultrasound to be superior to physical exam or history. Rapid determination of gestational age in the delivery room includes assessment of all areas of the feet, breast nodules, umbilicus, hair, and the external genitalia of males. Babinski born 36 wk and earlier the toes are usually partially descended, the scrotum is small with very few rugae. Term infants (39 wk and beyond) should have the toes fully descended, the scrotum should appear normal sized with prominent rugae.

Gibbon Classification of Voiding Dysfunction

Description: Historic classification based in large part on the system proposed by Ross-Comarr. 5 categories are proposed to be important: (1) Full general and neurologic diagnosis, (2) state of the bladder function, (3) state of the renal function in children with rare exception to as enuresis risoria, is urinary leakage that occurs exclusively occurs in girls. It is characterized by large-volume voids. These children have normal bladder function when the child is not laughing. The disorder is thought to be mediated by the central nervous system and has similarities to detrusor instability.

TREATMENT
- Treatment of this condition is not well studied
  - Anticholinergics (eg, oxybutynin)
  - Methylphenidate
- Biofeedback was effective in 1 series in patients refractory to medical management

Gill-Vernet Extended Pyelolithotomy

Description: An open approach to remove a large renal calculus, such as a staghorn calculus. Using a flank incision, the kidney is exposed and fixed at the upper pole, lower pole and posteriorly. The ureter is identified and traced to the renal pelvis. The renal pelvis is incised and the incision can be continued to include the calixi to allow for removal of more significant calculi.

Gill-Vernet Orthotopic Urinary Diversion

Description: A continuous segment of terminal ileum, cecum, and ascending colon is isolated. The unit is rotated 180° to allow anastomosis of the reduced end of the ascending colon to the urethra and the ureters to the terminal ileum.

Gill-Vernet Ureteral Reimplantation

Description: Through a transvesical approach, the ureters are dissected free from the hiatus. The principle involves advancing the ureters across the trigone to the midesophagus such that both ureters are intraurethral. A single incision is made in the trigone mucosa, which will allow to join traction sutures from each ureter that are anchored in the midline.

Gittelman Syndrome

Description: Gittelman syndrome is an autosomal recessive disorder characterized by hypertelorism, hypertelorism, and hypogonadism with mental retardation. It is caused by loss of function mutations of a thiazide sensitive sodium-chloride symporter found in the distal convoluted tubule of the kidney.

TREATMENT
- Replacement of respective electrolytes.

Gittes Needle Urethroscopy

Description: Needle used to treat female stress incontinence. A Stamey needle is delivered through a stab incision at the upper border of the pubis, then transferred under digital guidance through the anterior vaginal wall at the level of the bladder neck. A No. 2 prolene suture is used to suspend the bladder neck on both sides, and the vaginal sutures eventually cut through the wall and become buried in the incision. A single incision pubovaginal suspension as an adjunct to other pelvic-floor surgery. Obstet Gynecol. 1999;93(5):844–847.

Gleason Grade, Tertiary Pattern

Description: The standard Gleason grading system reports the primary and secondary Gleason pattern. The tertiary pattern (3rd most prevalent) is noted if it is high grade. Retrospective data suggest that a high-grade tertiary component after RP, even when present in a small percentage of total tumor volume, has prognostic significance. It’s presence is associated with biochemical recurrence and adverse pathologic features such as seminal vesicle invasion, extraprostatic extension, and positive surgical margins.

Gleason Grading/Scoring System

Description: A widely accepted system to describe the aggressiveness of prostate adenocarcinoma was developed by Dr. Donald Gleason between 1969 and 1974, in which prostate cancer mortality data were correlated to low-magnification architectural patterns of prostate carcinoma. 5 grades are described, ranging from well differentiated to undifferentiated. To account for variations within tumors, 2 grades are recorded. The predominant, or primary, grade and the less extensive, or secondary, grade. These are summarized to give the Gleason score. Gleason score is added together to obtain
GLEASON GRADING SYSTEM, MODIFIED

a Gleason grade of (3 + 4 = 7). The Gleason score is a strong independent predictor of cancer behavior and treatment outcome for prostate cancer patients. Pattern 3 is separated from pattern 4 because no statistically significant differences between Gleason score 6 from Gleason score 7 tumors, with the latter having a significantly worse prognosis.

Gleason pattern 1: Very well-circumscribed nodule of single, separate, closely packed, back-to-back glands. There is no infiltration into adjacent benign prostatic tissue. The glands are fairly large, round or oval, and are approximately equal in size and shape. Gleason pattern 1 is usually found in transition zone carcinomas and is rare. When present, it is usually associated with a pattern 2 tumor. Distinction from pattern 2 is not critical, as they have a similar prognosis.

Gleason pattern 2: Usually, but not always, seen in transition zone carcinomas. Well-circumscribed nodule of single, separate glands with the glands more loosely arranged and not as uniform as in pattern 1. Minimal invasion by neoplastic glands into the surrounding benign prostatic tissue. The cells are smoothly rounded or oval with open lumens and are not angular, as seen in pattern 3. The cytoplasm is more abundant and pale staining than intermediate-grade tumors.

Gleason pattern 3: Infiltrative with extension into adjacent benign prostatic tissue. The glands vary in size and shape and are often elongated or angular. These small glands are often called microglands and are usually smaller than Gleason pattern 1 or 2 glands. However, some of the glands of pattern 3 may be moderate to large sized. The small glands of pattern 3, in contrast to small poorly defined glands of pattern 4, are distinct glandular units and should be able to draw all imaginary circles around each of them. Crinoid glands may also be Gleason pattern 3. These small glands are irregularly larger than benign glands and having regular outer contours. They resemble interstitial cribriform carcinoma of the breast. Crinoid pattern 3 is distinct from Gleason pattern 4, interstitial cribriform proliferations, and prostatic duct adenocarcinoma.

Gleason pattern 4: The glands are no longer single and separate as seen in pattern 1–3. They are fused, poorly defined with only occasional luminal formation, or cribriform. Fused glands are chains, nests, or masses of glands that are no longer completely separated by intervening stroma. Fused glands contain more strands of residual stroma that may give the appearance of partial separation of the glands. Consequently, fused glands may have a scalloped appearance peripherally. The “reperinfracturate” pattern described by Desjardins is an uncommon variant of fused glands and resembles RCC. Cribriform glands of pattern 4 are either large cribriform glands (cribiform sheets) or small cribiform glands with irregular infiltrating borders. The small cribiform glands with irregular infiltrating borders of pattern 4 must be distinguished from cribriform pattern 3, in which the small cribiform glands have regular borders. Fragments of cribriform carcinoma in needle biopsies of the prostate imply a cribriform cancer and are designated pattern 4.

Gleason pattern 5: The tumor has virtually no glandular differentiation. It is composed of solid sheets, solid cords, or single cells. Nests of tumor with central comedo necrosis are also classified as pattern 5. It is controversial whether cribriform glands of cancer that otherwise would be considered Gleason pattern 4 should be considered Gleason pattern 5 if comedocarcinosis is present. Separating poorly defined pattern 4 glands from costs and nests of tumor with virtually no glandular differentiation or with only vacuoles is a problem, but usually not critical because any combination of the 2 patterns will lead to a Gleason score of 6–10, all of which are poorly differentiated (Image 2).

REFERENCE

GLEASON GRADING SYSTEM, MODIFIED

DESCRIPTION
The International Society of Urologic Pathology held a consensus conference in 2005 at which the "3rd Gleason grading system" for prostatic carcinoma from 1968 underwent its first major revision. With this modified grading system, a shift of the most frequent Gleason scores from 6–7a to 3–4–5 in biopsy specimens and an increased degree of agreement between specimen of biopsies and radical prostatectomies with carcinoma of the prostate could be demonstrated. After modified grading of GS 3 + 4 = 7a tumors, 95% were stage pT2, whereas 79% of GS 4 + 3 = 7b tumors were stage pT2–pT3. In cases with PSA <10 ng/mL, and tumor extent <20%, the most frequent Gleason scores were 6 and 7a. Cases with serum PSA >10 ng/mL, or tumor extent >20% had higher scores (Grades 4 or 5). Cancers with tumor involution of <1 mm in 1 of 12 cores and PSA <10 ng/mL, were mainly low grade (GS scores 6 and 7a) and may correspond to so-called insignificant carcinoma of the prostate. Using the modified Gleason grading system, grade, stage extent, and serum PSA showed good correlations and characterize the difference between low- and high-grade malignancy of the prostate.

REFERENCE

GLEINN-ANDERSON URETTERONEO CYSTOSTOMY

DESCRIPTION
Through a transvesical approach, the ureter is mobilized from its hilus and advanced toward the bladder neck through a submucosal tunnel, where it is reimplanted. Used to treat vesicoureteral reflux or resection of a ureteral orifice.

REFERENCE

GLOMERULOCYSTIC KIDNEY DISEASE (CORTICAL MICROCYSTIC DISEASE)

DESCRIPTION
Rare, bilateral cystic kidney disease that can be inherited (autosomal dominant) or sporadic. Presents most commonly in childhood with bilateral flank masses, which are large kidneys with many cysts. Seen rarely in adults with hypertension, hematuria, and end stage renal disease (ESRD). Cysts are confined to the cortex and arise from the Bowman space. Renal biopsy may be necessary to confirm diagnosis. Radiologically, the lesions are similar to autosomal dominant polycystic kidney disease (ADPKD). Treatment is supportive, with renal replacement therapy if renal failure occurs.

REFERENCE

GLomerulosclerosis

DESCRIPTION
An accumulation of homogeneous eosinophilic material in the glomerulus, made up of plasma proteins that have escaped from the plasma into glomerular structure; this is a light microscopic feature known as hyalinization. This change contributes to obliteration of capillary lumina of the glomerular tuft, a feature of glomerulosclerosis. Hyalinization and glomerulosclerosis are a consequence of endocardial or capillary wall injury and the end result of various forms of glomerular damage.

REFERENCE

GLUCAGON STIMULATION

DESCRIPTION
Indicated when the diagnosis of pheochromocytoma is highly suspected by history and clinical findings, but blood pressure is normal and diagnostic biochemical tests are equivocal (polaroid lines and modified adrenaline). The mode of action is the stimulation of glucagon-sensitive adenylate cyclase receptors expressed on the tumor, which can lead to dangerous rises in blood pressure; thus, this test is rarely used. A physician must be present throughout the test, and it should only be performed in patients whose blood pressure is well controlled, such as in plasma normotensive to >3–5-fold or >2,000 ng/mL is diagnostic of pheochromocytoma.

REFERENCE

GLUCOSURIA, RENAL

DESCRIPTION
Normal urine contains small amounts of glucose. Increased amounts represent either insufficient handling by the tubule or hyperglycemia. Diabetes is the most common cause of glycosuria. Causes of primary glycosuria are either intestinal glycosuria–galactosuria malabsorption or benign familial renal glycosuria. Some substances are known to cause false positive glucose readings on dipstick, such as ascorbic acid and salicylates. Medications such as ACE inhibitors may also have a direct effect on the kidney and cause glycosuria. Pregnancy can be
GOLDSMITH SYNDROME
DESCRIPTION Rare syndrome with principal features of kidney, liver, and brain abnormalities. The kidneys are cystic and large bilaterally. Histologic lesions of the liver are typical with a double band of fibrous tissue without bile ducts. The brain shows the Dandy-Walker malformation, which is the cystic dilatation of the 4th ventricle, secondary to obstruction of the foramina of Luschka and Magendie. Renal replacement therapy is indicated, and hydrocephalus requires a short areometry.

GONADAL DYSGENESIS, PURE
DESCRIPTION Gonadal dysgenesis syndrome includes Turner syndrome (45, X0), 46, XX “pseudosexual” gonadal dysgenesis, mixed gonadal dysgenesis (45, X0/46, XY), partial gonadal dysgenesis (aka, dysgenetic mixed gonadal dysgenesis), and bilateral vanishing testis syndrome. It is the 2nd most common cause of ambiguous genitalia in the newborn after CAH. Mixed gonadal dysgenesis is characterized by unilateral tests, often intra-abdominal, contralateral streaked gonads, and persistent müllerian structures with varying degrees of inadequate masculinization (“testis plus streak gonad”). A streak gonad is dysgenetic and resembles ovarian stromal tissue, but no germ cells are present. US usually testis is 45, X0/46, XY mosaicism. Phenotype is variable, ranging from a female with Turner syndrome to ambiguous genitalia, to (rarely) normal-appearing males. Almost all have a uterus, vagina, and tubal fimbriae, but with varying degrees of phallic development, labioscrotal fusion, and undescended testes. Increased risk exists of gonadoblastoma (incidence 20%) in either dystrophic tissue or streak gonad (more frequently tested), as well as an increased risk of Wilms tumor. Clinical diagnosis is birth and with confirmatory karyotyping. (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "Gonadal Dysgenesis, Pure.")
TREATMENT
- Determine gender assignment, based upon potential for normal function of external genitalia and gonads
- Perform appropriate sex and growth hormone replacement

GOODPASTURE SYNDROME
DESCRIPTION Characterized by a triad of pulmonary hemorrhage, iron deficiency anemia, and glomerulonephritis (GN), representing <1% of all cases of GN. Anti-GBM antibody deposition in the lungs and kidney is the cause. Antibody production appears to be self-limited. Histologically, it shows focal proliferative and necrotizing glomerular lesions that progress rapidly to diffuse proliferation with crescents. Immunohistochemical studies show diffuse linear deposition of IgG along the GBM. Primarily a disease of young white males (male:female, 6:1) with a mean age of 21. About 1/3 of patients die of pulmonary involvement. Renal involvement is usually severe and progressive, with rapid development of oliguria and renal failure.
TREATMENT
- Steroid pulse therapy with prednisone
- Plasma exchange therapy to remove circulating anti-GBM antibody
- Cyclophosphamide to inhibit further antibody formation
- Renal replacement therapy for ESRD

GOODWIN URETERAL ANASTOMOSIS
DESCRIPTION Through a transcutaneous approach, a nonhealing anastomosis is performed by raising a tunnel of muscosa with a mosquito hemostat for a 3–4 cm distance, then exiting the bowel wall. The ureter is grasped and pulled through the tunnel. The spatulated ureter is anastomosed to the colorectal muscosa while incorporating some muscularis for security.
SYNONYMS
• Nevoid basal-cell carcinoma syndrome
• Basal cell-nevoid syndrome

REFERENCE

GOUT, UROLOGIC CONSIDERATIONS

DESCRIPTION
An inherited disorder of purine metabolism characterized by elevated serum urate levels and severe recurrent arthritis, gout leads to an increased risk of urate urolithiasis and uric acid nephropathy. Most patients with uric acid stones, however, do not have gout. About 25% of patients with gout will develop a stone. Gout may also produce a type IV RTA, resulting in hyperkalemia and a mild metabolic acidosis. (See Section I: “Renal Tubular Acidosis”, Section I: “Urinophilia, Uric Acid Acidosis”.)

TREATMENT
• Alkalization of urine and increasing urine output help prevent stones.
• Allopurinol or following a low-purine diet will help prevent stones.

REFERENCE

GUONERVEUR SYNDROME
DESCRIPTION
Classic presentation of vesicovaginal fistula, with suprapubic pain, urinary frequency, dysuria, and tenesmus.

REFERENCE

GRANULOMA INGUINALE (DONOVANOSIS)
DESCRIPTION
Ulcerative disease of the genitals with significant scirrhous lymphadenopathy, caused by Klebsiella granulomatis (formerly known as Calymmatobacterium granulomatis). The disease occurs rarely in the United States and is endemic in some tropical and developing areas (India, Papua, New Guinea, the Caribbean, central Australia, and southern Africa). Clinically, the disease is commonly characterized as painless, slowly progressive ulcerative lesions on the genitals or perineum without regional lymphadenopathy; subcutaneous granulomas (pseudolymph nodes) may also occur. The lesions are highly vascular (i.e., red, soft appearance) and bleed easily on contact. Ulceration at site inoculation may be on the genitals or extragenital sites, and prominent lymphadenopathy often results in further skin ulceration over the nodules. Ultrasound results in lymphadenoma and genital involvement. See also Section I: “Sexually Transmitted Infections (STI); Sexually Transmitted Diseases (STD)”. Diagnosis is based on rapid Giemsa stained-smear of ulcer (RapiDiff), to look for Donovan bodies. For smear-negative cases, biopsy of the ulcer is necessary. Culture and PCR are available only in specialized centers.

TREATMENT
• Diocycline 150 mg orally twice a day for at least 3 wk and until all lesions have completely healed.
• Alternative regimens (treat until all lesions healed):
  • Azithromycin 1 g orally once per week for at least 3 wk or
  • Ofloxacin 750 mg orally twice a day for at least 3 wk.

GRANULOSA CELL TUMORS
DESCRIPTION
The most common ovarian neoplasm. Usually small, cystic, unilateral, and secretes estrogens. Often presents in childhood as precocious puberty or as postmenopausal bleeding in older women. During the reproductive years, prolonged and irregular bleeding and a pelvic mass are most common. These tumors can also present with urinary symptoms, and they can rarely be present in the testes.

TREATMENT
• Surgical excision is usually curative.
• Close follow-up of the contralateral ovary is necessary.

REFERENCE

GRANULOCYTIC EVIDENCE OF SEXUAL SATISFACTION
DESCRIPTION
A validated psychometric instrument intended for heterosexual couples or individuals. The questionnaire is based on a 28-item scale, with separate forms for men and women. It contains subcales of ED, organic disorders, vaginismus, and male and female nonsensuality. It may be used in individuals undergoing marital or sex therapy.

REFERENCE

GROIN HERNIA, PEDIATRIC
DESCRIPTION
The most common surgry in the pediatric age group. Most hernias in this population are indirect and congenital. The incidence is higher in persons born with a male to female ratio of 6:1. The hernia is formed from the persistence of the processus vavghanii and can present as a communicating hydrocele, hydrocele of the cord, simple hydrocele, or hydrocele of the cord.

REFERENCE

GRAVITATION DISORDER
DESCRIPTION
Also known as resistive manueulation, usually peaks at 4 yo but can be seen at as young as 3 mos of age. The disorder may occur in the absence of genital manipulation and can consist of vocalizations with quiet grunting, diaphoresis, and pressure on the perineum with characteristic posturing of the lower extremities. The patient is commonly referred for seizures or a movement disorder because of the recurrent paroxysmal movements.

REFERENCE

GRISSEX SEX FUNCTION INDEX (GOLombok–Rust INVENTORY OF SEXUAL SATISFACTION)
DESCRIPTION
A validated psychometric instrument intended for heterosexual couples or individuals. The questionnaire is based on a 28-item scale, with separate forms for men and women. It contains subcales of ED, organic disorders, vaginismus, and male and female nonsensuality. It may be used in individuals undergoing marital or sex therapy.

REFERENCE
**HEIKEL–PARKKULAINEN REFUX CLASSIFICATION SYSTEM**

**REFERENCE**

**HAND FOOT SYNDROME**

**DESCRIPTION**

Many oncologic medications have been implicated (such as capecitabine, fluorouracil, others), but this condition appears to be a relatively common problem with multikinase inhibitors such as sunitinib and sorafenib, which are used to treat tumors such as metastatic renal cell carcinoma (RCC).

**SYMPTOMS**

- Palm–plantar erythrodysesthesia (PPE)
- Malignant palmar–plantar toxicity

**TREATMENT**

- Reduce exposure of hands and feet to friction and heat (ie, hot water, avoid pressure on feet, avoid using tools, cool hands and feet with an ice pack, moisturizing creams).

- Stopping the medication temporarily reduces the symptoms. The drug can often be restarted at a lower dose.

**REFERENCES**

Hauptmann Pouch

**DESCRIPTION**

This ileal neobladder is created from 70 cm of ileum, starting 15 cm from the ileocecal junction. The bowel is opened up along the antimesenteric border, and lesions are seen in the transitional areas (ie, urothelial, gland, and peripheral areas). Lesions heal without scarring. Treatment involves antibiotics for superinfection, steroids, and dermabrasion.

**REFERENCES**

**HAILEY–HAILEY DISEASE (OXENFAMILIAL PEMPHIGOID)**

**DESCRIPTION**

Autoimmune skin disease arising from mutations of the ATP2C1 gene. The appearance begins as a fluid vesicle or bulla with associated itching, irritation, and a possible odor. The lesions may erupt and leave crusted erosions, and some may have a dry center and inflammatory periphery. The onset usually occurs within the 2nd–3rd decades of life, and lesions are seen in intertriginous areas (ie, axillary fold, groin, and perilveal areas). Lesions heal without scarring. Treatment involves antibiotics for superinfection, steroids, and dermabrasion.

**REFERENCES**

**HALD–BRADLEY CLASSIFICATION OF VOIDING DYSFUNCTION**

**DESCRIPTION**

Based on the anatomic location of the urologic lesion, voiding dysfunction is broken down into 3 classes: (1) suprapubic, (2) supravesical spiral, (3) influence, (4) peripheral autonomic neuropathy, and (5) muscular lesions. Examples include coordinated voiding with hyperreflexia in suprapubic lesions, whereas muscular lesions may be a decompensated bladder from long-standing bladder outlet obstruction.

**REFERENCES**

**KIDNEY**

**DESCRIPTION**

The kidney is subject to the majority of external injuries in the GI system. Hematuria is a good indicator of injury but its amount or absence does not eliminate renal injury or does it dictate the degree of injury. Any degree of hematuria in penetrating trauma should prompt imaging. Kidney injury is graded from I–V in accordance with the American Association for Surgery of Trauma Organ Injury Severity Scale for the Kidney. In carefully selected patients, management can be nonoperative, with careful observation or segmental embolization used. Absolute indications for surgical exploration include expanding perirenal hematoma, evidence of persistent renal bleeding, and palpable perineal hematoma. Relative indications include urinary extravasation, irreversible tissue, delayed diagnosis of arterial injury, segmental arterial injury, and incomplete staging. (See also Section I: “Renal Trauma, Adult.” Section I: “Renal Trauma, Pediatric,” Section II: “American Association for Surgery of Trauma Organ Injury Severity Scale.”)

**REFERENCES**

**EXTERNAL GENITALIA**

**DESCRIPTION**

Refers to an enlarging mature teratoma or a growing teratoma syndrome: urogenital syndrome. GROWING TERATOMA SYNDROME

**DESCRIPTION**

Refers to an enlarging mature teratoma or a growing teratoma syndrome: urogenital syndrome. The genitalia have several characteristics that are somewhat protective against sustained injury. Characteristics such as the salinity of skin, flaccidity, and multiple sources of blood supply assist with dampening the blow of trauma and help with reconstruction efforts. Nevertheless, the location of major vasculature and visceral organs make these injuries potentially life-threatening. Greater than 50% of injuries to the penis have urethral injuries and 75% have other significant associated injuries. A majority of these injuries require exploration with capsular irrigation, excision of foreign material, antibiotics, and primary closure. In injuries to the urethra, imaging such as retrograde urethrogram should be implemented and, if warranted, abdominal pelvic imaging should be obtained. (See also Section I: “Penis, Trauma,” Section I: “Scrotum and Testicle, Trauma.”)

**REFERENCES**

**GUAILLAN–BARRY (TRANSVERSE MYELITIS) SYNDROME: UROLOGIC CONSIDERATIONS**

**DESCRIPTION**

Also known as acute inflammatory demyelinating polyradiculoneuropathy, an inflammatory demyelinating disorder of the autonomic and peripheral nerve systems. It is thought to be triggered by a bacterial or viral antigen, causing the immune system to cross-react and attack neural tissue. Symptoms may include muscle weakness, respiratory difficulties, autonomic neuropathy, and cardiac, bowel, bladder, and sexual dysfunction. Lower urinary tract dysfunction can range from urgency and stress incontinence to urinary retention.

**TREATMENT**

- Manage lower urinary tract dysfunction (Clean intermittent catheterization [CIC], anticholinergics, etc.)
- Intravenous immunoglobulin

**REFERENCE**

HEMATOCELE

DESCRIPTION
Collection of blood within the layers of the tunica vaginalis. Hematocele can present as scrotal swelling and may be asymptomatic. It may be difficult to distinguish from tumors, in which case transcutaneous ultrasonography (US) is helpful. Causes include trauma, infection, bleeding disorders, tumors, and rarely uremia. (See also Section I: “Scrotum and Testicle, Trauma.”)

TREATMENT
Conservative management if patient asymptomatic and diagnosis confirmed. Often, diagnosis by surgical exploration is described mostly in adults after a history of trauma, infection, bleeding disorders, tumors, and rarely uremia.

REFERENCE

HEMATUROA, ATHLETIC (RUNNERS’ HEMATURIA)

DESCRIPTION
Described mostly in adults after strenuous exercise. The phenomenon of gross or microscopic hematuria can occur in contact or noncontact sports. The WBCs seen in the urine may be glomerular or nonglomerular in shape. The cause of the hematuria can be from trauma of the posterior bladder wall hitting against the bladder base. Nontraumatic causes are hypothesized to be from changes secondary to the vasodilatation of the glomerular and renal vessels or to constriction of the effluent glomerular arterioles resulting in increased filtration pressures in the kidney. The hematuria should be distinguished from myoglobinuria and hemoglobinuria.

SYNONYMS
• Sports hematuria
• Athletically induced hematuria

TREATMENT
• Should be limited and provoked by strenuous exercise.
• Co-existing urologic pathology should be ruled out.

REFERENCE

HEMATURIA–DIURESIS SYNDROME

DESCRIPTION
Hematuria–diuresis syndrome is the most common reported complication of gastrocystoplasty. The syndrome of diuresis and hematuria is defined as or a combination of the following symptoms: bladder spasm or suprapubic, penile or perineal pain, coffee brown or bright red hematuria without infections, skin irritation or excoriations, and diuresis without infections.

REFERENCE

HEMATURIA–LOIN PAIN SYNDROME

DESCRIPTION
A cause of recurrent gross hematuria that may be confused with IgA nephropathy, loin pain–hematuria syndrome generally affects young women and is characterized by recurrent episodes of gross hematuria associated with dull unilateral or bilateral loin pain and sometimes low-grade fever. BP and renal function are usually normal. The syndrome has been associated most often with the use of oral contraceptive agents and generally resolves when these agents are discontinued. Renal autotransplantation has been described as a treatment modality.

REFERENCE

HEMIZONA ASSAY

DESCRIPTION
This assay assesses the ability of sperm to bind to the zona pellucida of the egg. It is performed by dividing intact zona pellucida and incubating it separately with donor sperm and the patient’s sperm. A hemizona index is derived by dividing the number of bound donor sperm by the number of bound patient sperm. An index <0.80 is seen in males who failed IVF. Its use is limited by the availability of human ova. Since this technique potentially bypasses the step of zona binding, men whose sperm cannot bind may be good candidates for these procedures.

REFERENCE

HEMORRHAGE, POSTOPERATIVE, UROLGIC CONSIDERATIONS

DESCRIPTION
Postoperative hemorrhages can occur after any urologic procedure, but are most common and significant with percutaneous procedures of the kidney. The risk of hemorrhage increases in patients with underlying coagulopathy, aberrant anatomy, multiple needle passages, tract dilatation, or nephrostomy tube placement. Parenchymal bleeding can be persistent, and a large high pressure balloon can be placed through the nephrostomy tube tract to promote tamponade and hemostasis. Not uncommonly, venous lacerations may occur and can be managed by placing a large nephrostomy tube and clamping the tube to allow for tamponade. If arterial bleeding is persistent, selective arterial embolization may be employed. Delayed bleeding can occur soon after surgery, or weeks to months later in the setting of renal pseudoaneurysms or arteriovenous fistulas. If these diagnoses are suspected, evaluation with angiography and treatment with selective embolization can be performed.

REFERENCE

HEMORRHAGE, RETROPERITONEAL AND PERINEPHRIC

DESCRIPTION
Retroperitoneal and perinephric hemorrhage are uncommon in the absence of trauma. Spontaneous retroperitoneal and perinephric hemorrhage is most commonly from the kidney. The most common renal causes are angiolipoma (AML) and renal cell carcinoma (RCC). Vascular diseases such as polyarteritis nodosa (PAN), renal artery aneurysm, infections of kidney such as cortical abscesses, perinephritis, and renal cysts are occasional etiologic factors. Adrenal hemorrhage (AH) is seen with severe stress conditions (lapses, burns, trauma), pheochromocytoma, adrenal carcinomas, myelolipoma, and cortical adrenocortical. Clinical presentation depends on the amount of bleeding ranging from mild flank pain to shock and oliguria. CT scan is considered the gold standard for diagnosis. (See also Section I: “Retroperitoneal Masses, Fluid and Cysts” and Section II: “Retroperitoneal Hematoma.”)

REFERENCE

HEMOSIDERIN, URINARY

DESCRIPTION
Hemosiderin occurs when hemoglobin is reabsorbed by the proximal tubular cells and then catalyzed into heme and hemosiderin. Uremic hemosiderin can occur up to 2 days after an acute hemolytic episode, and is also demonstrated in chronic hemolytic states and hemochromatosis.

REFERENCE

HENCHO–SCHÖNLEIN PURPURA (HSP)

DESCRIPTION
HSP is a form of purpura with an underlying pathologic feature of vasculitis, affecting mainly small blood vessels. The disease is predominantly seen in children. Clinically, the purpuric skin lesions are typically located on the lower extremities. However, the hands, arms, and face can be affected. Joint pain, abdominal pain, and gastrointestinal bleeding may be present. Hematoma denotes a renal lesion, which is usually reversible. HSP is similar to IgA nephropathy, but somewhat more severe, particularly in adults. Progressive renal failure occurs in at least 25%. Kidney biopsy reveals segmental glomerulonephritis with crescents and mesangial deposition of IgA and complement types C3 and C4. Lab tests reveal mild to normal to high protein counts. Clinical involvement is not severe, the disease will subside without sequelae within 6 wk.
HLRCC syndrome is manifested by:

**DESCRIPTION**

- Renal cell carcinoma
- Hereditary leiomyomatosis and renal cell carcinoma syndrome

**TREATMENT**

- Early diagnosis and close follow-up
- Nephrectomy (partial or radical) when indicated

**REFERENCE**

**HEDRATIS PAPILLARY RENAL CELL CARCINOMA (HPVCC)**

**DESCRIPTION**

HPVCC is an autosomal dominant disorder associated with type 1 papillary RCC. Acquired as a proto-oncogene, rather than inactivation of a tumor suppressor gene, is the initiating event. Missense mutations of the c-KIT proto-oncogene on chromosome 4 at 4q11 are the most often described as the relevant genetic locus causing the disorders. A majority of the mutations were isolated on the tyrosine kinase domain of the c-KIT gene. Tumors linked to these mutations are thought to be less aggressive than the sporadic type. (See also Section I: “Renal Cell Carcinoma, General.”)

**REFERENCES**

**HERNIA UTERINE INGUINALE**

**DESCRIPTION**

A cause of male pseudohermaphroditism, thought to be due to an isolated defect in the production of mullerian inhibiting substance or to the response to mullerian inhibiting factor (MI). This is a rare syndrome of mullerian ducts persistence. Affected males are not ambiguous at birth and generally present later, most commonly with an inguinal hernia on 1 side and an irreducible contralateral testis. Hernia sac may extend into the uterus. Karyotype is 46, XY. The involved tissue is exclusively testicular. Both Wolffian and mullerian duct derivatives are present, with a vagina and epididymis alongside an epididymal vesicle, fallopian tube, and upper vagina. Tests have malignant potential. No uterine or vaginal malformation have been reported.

**TREATMENT**

- Sex assignment as male
- Primary or staged orchidopexy
- Müllerian structures do not require removal, as the Mullerian inhibiting substance or the response to Müllerian inhibiting factor may be effective

**REFERENCE**

**HIDRADENITIS SUPPURATIVA (ACNE INVERSA), UROLOGIC CONSIDERATIONS**

**DESCRIPTION**

A chronic suppurative disease of the apocrine gland-bearing areas of the body, such as the axilla, buttok, and groin. Not primarily infectious; caused by plugging of the follicles. Diagnosis is usually accomplished by location and clinical course. Pain, fluctuation, discharge, and sinus tract formation are characteristic. In chronic cases, coalescence of inflamed nodules may cause palpable cordlike bands. The condition may become extensive and disabling. If the pubic and perineal areas are severely involved, walking may be difficult.

**TREATMENT**

- Avoid irritants such as antiperspirants
- Conservative treatment with rest, moist heat, and prolonged antibiotics (tetracycline or erythromycin)
- Oral isotretinoin and intralavital corticosteroids may be effective
- Surgical excision and plastic repair of the affected areas may be necessary

**REFERENCE**

**HINMAN SYNDROME (HINMAN–ALLEN SYNDROME):**

**HINMAN SYNDROME (HINMAN–ALLEN SYNDROME) (NONNEUROGENIC OCCULT NEUROPATHIC BLADDER) (OCCULT NEUROPATHIC BLADDER)**

**DESCRIPTION**

It was described in 1937 by Hinman and Baum, this is a syndrome of vesicovaginal dysfunction (dyssynergic voiding) that is associated with recurrent UTIs, vesical trabeculation, poor emptying, and hypertension with possible progression to renal failure. Hinman syndrome is thought to occur from bladder vesicovaginal dysfunction with no signs of neurologic cause and may begin in the neonate or in the child around the time of bladder training.

**SYNONYM**

Nonurogenic neuropathic bladder

**TREATMENT**

- Clean intermittent catheterization (CIC)
- Catheter vesicostomy

**REFERENCE**

HISPAREUNIA (MALE DYS Pareunia)

REFERENCE

HISPAREUNIA (MALE DYS Pareunia)
DESCRIPTION
Sling erosion/isolation is a recognized complication after suburethral sling (or to treat female stress urinary incontinence [SUI]). Erosion occurs in up to 4% of patients. Female symptoms may include discharge, infections, postcoital bleeding, and alterations of the sexual function. Changes of male sexual function and particularly pain again after sling insertion in their female partner may be due to sling exposure and has been termed “hispareunia.” Sexual interest and drive may be negatively influenced. Male dyspareunia is a complaint that appears to be effectively treated by correcting the sling exposure in the female partner.

REFERENCE

HISTOPLASMOsis, GEnITOURINARY
DESCRIPTION
Histoplasma capsulatum grows in soil entombed by bird guano, with outbreaks reported in caves, construction sites, and on bird farms. Disseminated violent disease is seen in AIDS, children, and immunosuppressed individuals. GI involvement is a manifestation of systemic disease and can result in sloughed papilla, prostatic obstruction, or prostatic abscess. Epiphonitis can resemble sperm granulomas. Up to 1% can experience adrenal insufficiency from adrenal destruction. (See also Section I: “Fungal Infections, Gastrointestinal.”)

TREATMENT
2 g of amphotericin B with maintenance therapy with fluconazole to prevent relapse

REFERENCE

HIV NEPHROPATHY
DESCRIPTION
HIV nephropathy [HIVNA] is the most common cause of chronic renal failure among HIV+ asymptomatic patients. It can occur in both the acute and chronic phase of the illness. Presentation may include nephrotic syndrome, hypertension, hematuria, and renal insufficiency. Pathologically, there is a focal segmental glomerulosclerosis, collapsing nephropathy with podocyte hypertrophy, and hyperplasia. (See also Section I: “HIV/AIDS, Urologic Considerations.”)

TREATMENT
- High-dose antiretroviral therapy
- Steroids
- ACE Inhibitor

REFERENCE

HODGKIN DISEASE, UROLOGIC CONSIDERATIONS
DESCRIPTION
Hodgkin disease is a type of lymphoma differentiated from other lymphomas partially on the basis of the presence of Reed–Stemmer cells. It has become 1 of the most curable forms of malignancy. It has many urologic associations, and an association with a higher incidence in RCC patients has been proposed. Treatment with radiation for Hodgkin may predispose to bladder cancer. The kidney and bladder have been reported to be primary sites of Hodgkin disease. Extensive retroperitoneal lymphadenopathy may cause ureteral obstruction. Renal radiation-induced arterial stenosis can be a treatment effect. (See also Section II: “Symptoma, Urologic Considerations.”)

REFERENCE

HODGKSON TYPES I, II, III HYPOSPADIAS REPAIR
DESCRIPTION
Type I: Chordee is repaired. A longitudinal slit along the urethral axis is formed on the inner surface of the prepuce, which is then transferred to the ventrum through a buttonhole incision at the base of the tube. The proximal neourethra is anastomosed to the proximal native urethra, and the distal neourethral tube is used to create the meatus. Type II: Hodgkin modified type I for the very distal hypospadias where no chordee exists, and the native urethral plate remains intact. The inner surface of the prepuce is again transferred to the ventrum via a buttonhole at the base. In this repair, the proximal flap is sutured onto the urethral plate. Type III: This is modified for the more proximal hypospadias repair. Here, the buttonhole is created at the base of the penis, and a longer tubular neourethra is created, based on preputial and shaft skin.

REFERENCE

HONEYMOON CYSTITIS
DESCRIPTION
Urinary tract infection which affects young sexually active women. It accounts for 4% of UTIs and for 75–90% of episodes in young sexually active women. The pathogenesis of this condition is caused by fusion of the female's urethra to bladder cancer. The kidney and bladder have been reported to be primary sites of Hodgkin disease. Extensive retroperitoneal lymphadenopathy may cause ureteral obstruction. Renal radiation-induced arterial stenosis can be a treatment effect. (See also Section II: “Symptoma, Urologic Considerations.”)

REFERENCE

TREATMENT
• High fluid intake
• Postcoital voiding (controversial if useful)
• Identify any triggers (Spermicide, positioning during sexual activity, etc.)
• Consider single dose of antibiotic before or after intercourse if ≤ 3 symptomatic UTIs/yr (eg, trimethoprim/sulfamethoxazole, trimethoprim, nitrofurantoin, cephalaxin, ciprofloxacin, others)

REFERENCE

HORSESHOE KIDNEY
DESCRIPTION
The most common fusion anomaly, present in 1 in 400 births, with a male predominance. Usually, this represents a true fusion of the lower poles, which may be composed of thick functioning parenchyma or merely a fibrous band. Associated anomalies are seen in 1/3 of patients and include multisystem disturbances of the skeletal and cardiovascular systems and GI tract, as well as GI abnormalities, such as an increased frequency of ureteral duplication, reflux, and dysplasia. Usually asymptomatic, a horseshoe kidney may be associated with urolithiasis and UO infection. Radiographic diagnosis can be made with IVP or CT, which reveals deviation of the axis of the kidney. Renal scan may be helpful in surgical decision making. If necessary, the condition is caused by fusion of poles during ascent of the kidneys. (See also Section 1: “Renal Fusion Anomalies.”)

TREATMENT
• Postcoital voiding (controversial if useful)
• Identify any triggers (Spermicide, positioning during sexual activity, etc.)
• Consider single dose of antibiotic before or after intercourse if ≤ 3 symptomatic UTIs/yr (eg, trimethoprim/sulfamethoxazole, trimethoprim, nitrofurantoin, cephalaxin, ciprofloxacin, others)

REFERENCE

HORTON-DENVEN “FLIP-FLAP” HYPOSPADIAS REPAIR
DESCRIPTION
The distal ventral skin over the urethral meatus, and the distal urethra is also mobilized. Parallel incisions are made in the glans to mobilize. The proximal flap is sutured over and onto the urethral plate. The wings of the glans are then approximated over this distal repair.

REFERENCE

HOUSNFIELD UNITS
DESCRIPTION
Named after Sir Godfrey Newbold Hounsfeld, the inventor of the CT scanner. It is an arbitrary scale created to compare density of different substances seen on CT. Water is represented by 0 HU. Air is –1,000 HU. Bone is 1,000 HU. Fat is in the range of...

Hypercalciuria is the most

**DESCRIPTION**

**REFERENCES**

Cystitis, Hemorrhagic [Infectious, Noninfectious, Cystitis. (See also Section I: “Fournier gangrene”; Section II: “Cystitis: Radiation.”)

**HYPERCALCEMIA, UROLOGIC CONSIDERATIONS**

**DESCRIPTION**

In urology, hypercalciuria is generally the result of metastatic lesions to bone, hydrochlorothiazide therapy, hyperparathyroidism, or chronic renal failure. Symptoms include anorexia, weakness, constipation, polyuria, and coma. This condition may also occur as a paraneoplastic syndrome from RCC and can lead to hypercalcemia, which can increase chances of urolithiasis.

**TREATMENT**

- Initial therapy involves diuresis by nonthiazide diuretics and IV saline.
- Inorganic phosphate and EDTA may be used for an emergency.
- Mitomycin, strontium, and etidronate disodium have also been used.

**REFERENCE**

**HYPERCALCIURIA (ABSORPTIVE, RENAL, AND RESORPTIVE)**

**DESCRIPTION**

Hypercalciuria is the most commonly associated metabolic abnormality in patients with calcium nephrolithiasis. Defined as urinary excretion of ≥275–300 mg of calcium per day in men or ≥250 mg of calcium per day in women on a regular unrestricted diet. An alternative definition in patients on a calcium-restricted diet (400 mg calcium, 100 mg calcium) is a urinary calcium level of ≤8 mg/L and a urine level of ≥200 mg of calcium,ermen.

**REVIEW**

**HYPERCALCIA DURING LAPAROSCOPY**

**DESCRIPTION**

CO2 is the most abundantly used insufflant in the United States for laparoscopic surgery. CO2 has the ability to diffuse easily into body tissues and out of the peritoneum during surgery. This can lead to increases in blood levels or hypercalciuria that can stimulate the sympathetic nervous system, leading to increases in vascular resistance, tachycardia, and impaired cardiac contractility. Patients who have pulmonary compromise (ie, COPD, fibrosis) may have difficulty compensating for the increased CO2 levels. Rarely a CO2 gas embolism may occur.

Unlike primary hyperparathyroidism, serum calcium is normal and the hyperparathyroidism is secondary.

**Absorptive hypercalciuria,** The hypercalcemia is due to primary hyperparathyroidism with excessive reabsorption of bone resulting from hypercortisolism of PTH. Intestinal absorption of calcium is frequently elevated because of the PTH-dependent stimulation of the renal synthesis of 1,25–(OH)2D.

As a guide to testing for hypercalciuria, calcium load usually consists of 1 g of oral calcium gluconate.

**TREATMENT**

- General recommendations include increased urine volume to ≥2 L/d; do not use calcium-restricted diet, but avoid excessive intake of dairy products, salty foods, and red meat protein. (Note: A low calcium intake increases intestinal oxalate absorption, with a subsequent increase in urinary oxalate stone formation.) Patients may be at risk for osteoporosis and osteodensity.
- Absorptive hypercalciuria: Thiazide is not a selective therapy for absorptive hypercalciuria, since it does not decrease intestinal calcium absorption. However, this drug is used because of its hypocalcic action and the high cost and inconvenience of alternative therapy (sodium citrate phosphate).
- Absorptive hypercalciuria type I: Thiazide does not correct the basic, underlying physiologic defect in absorptive hypercalciuria.
- Potassium supplementation (as potassium citrate), to prevent hypokalemia and hypocitraturia (eg, potassium chloride 50 mg/d, or indapamide 2.5–5 mg/d). Potassium supplementation (≥40 mg/d) is required to prevent hypokalemia and attendant hypercalcemia. Potassium chloride has been shown to be effective in preventing hypercalcemia and in increasing urinary citrate when administered to patients with calcium nephrolithiasis taking thiazides.
- Thiazide in combination with thiazide may be more effective than thiazide alone in reducing calcium excretion.
- Potassium supplementation should be used with caution in patients taking amiodole: Thiazides may lose their hypocalcic effect over time and cause hypokalemia, hypercalcemia, and increased urine acid.
- Recent data suggest bisphosphonates (eg, alendronate [Fosamax], risedronate [Actonel], and ibandronate [Boniva]) increase bone deposition of calcium and reduce urinary calcium levels.
- Absorptive hypercalciuria type II: No specific drug treatment may be necessary since the physiologic defect is not as severe as an absorptive hyperparathyroidism. Low calcium intake (400–600 mg) and high fluid intake (sufficient for a minimum urine output ≥2 L/d) is helpful. Normo-calcia can be restored by dietary calcium restriction alone, and increased urine volume has been shown to reduce urinary saturation of calcium.
- Absorptive hypercalciuria type III (renal phosphate leak) is treated with slow-release neutral potassium phosphate (Neutral-Phos P) that corrects the hyperphosphatemic.
- Renal hypercalcemia:
  - Thiazide diuretics augment calcium reabsorption in the distal tubule, causes extracellular volume depletion, and stimulates proximal tubule reabsorption of calcium. Agents include hydrochlorothiazide 50 mg BD, chlorthalidone 50 mg/d, or indapamide 1.25–2.5 mg/d. Potassium supplementation (≥40 mg/d) is required to prevent hypokalemia and attendant hypercalcemia. Potassium chloride has been shown to be effective in preventing hypercalcemia and in increasing urinary citrate when administered to patients with calcium nephrolithiasis taking thiazides.
  - Thiazide is contraindicated because of the risk of transtran renal stone formation.
- Resorptive hypercalciuria: Parathyroidectomy is the optimum treatment.

**REFERENCE**

of the geroinvasive tract (Fournier gangrene) have been described. Hyperparathyroid has also been reported in the treatment of meninistion cystitis. (See also Section I: “Fournier gangrene”; “Cystitis, Hemorrhagic [Infectious, Noninfectious, Radiation.”) and Section II: “Cystitis: Radiation.”)
**HYPERCONTINENCE**

**DESCRIPTION** A condition described in the literature referring to the increased likelihood that females are more likely to require intermittent catheterization than females following a cystectomy or urinary diversion such as orthotopic neobladder.

**HYPERKALEMIA, UROLOGIC CONSIDERATIONS**

**DESCRIPTION** Hyperkalemia usually occurs in urologic patients as a result of renal insufficiency, Addisonian crisis, trauma, shock, and diabetic acidosis. It can also be a consequence of small bowel substitution used in urinary diversion. ECG changes are characteristic, including prolonged T waves, long QT interval, long QRS complex, and absent P wave.

**TREATMENT**

1. Monitor patient on ECG if symptomatic or if K+ > 6.5 mEq/L, discontinue all K+ intake, including IV fluids; order a repeat stat K+
2. Pseudohyperkalemia should be ruled out. If doubt is present.
3. Rapid correction: These steps only protect the heart and are not adequate for other organ systems.
   - Sodium polystyrene sulfonate (Kayexalate) 20–60 g PO with 100–200 mL of sorbitol or 40 g of milk of magnesia in a heparinized tube; order a repeat stat K+
4. Combined sodium and water losses (hypovolemic hypernatremia): Water loss in excess of Na+
5. Hypervolemic hypernatremia: Avoid medications that contain excessive Na+
6. Enteric hyperoxaluria: Accounts for a relatively small number of cases of hyperoxaluria (5%). Caused by chronic diarrhea and malabsorption (cortis or jejunal bypass). Through the reduced GI calcium availability to bind oxalate and keep it from being absorbed systemically.
7. Diabetic hyperkalemia: Caused by increased intake of foods high in oxalates (i.e., nuts, chocolate, tea, spinach, rhubarb, beets, wheat bran, strawberries, and other plant products). Reduced dietary calcium intake can also result in hyperkalemia due to reduced intestinal binding of oxalate and increased oxalate absorption.
8. Idiopathic: The most common cause; may be due to increased dietary absorption or due to increased intrinsic production of oxalate, with some suggestions of a genetic predisposition.

**HYPEROXALURIA, UROLOGIC CONSIDERATIONS**

**DESCRIPTION** Hyperoxaluria in the urologic patient can result from iatrogenic causes and various disease states. Classified according to the mechanisms described below, the symptoms depend on the absolute level and also how rapidly the Na+ level has changed. Symptoms may include confusion, irritability, lethargy, stupor, coma, muscle twitching, and seizures. Signs can include hyperreflexia and mental status changes.

- Combined sodium and water losses (hypovolemic hypernatremia): Water loss in excess of Na+ causes intracellular K+ to shift. If serum Na+ remains normal, but total body water is decreased. Caused by diabetic insipidus (DI) (central and nephrogenic), excess skin losses, respiratory loss, others.
- Excess sodium (hypernatremic hyperkalemia): Total body Na+ increased. Caused by iatrogenic Na+-administration (i.e., hypertonic dialysis), hypernatremic saline enemas, Na-containing medications) or other excessive sources (massive ingestion, salt tablets) or adrenal hyperfunction (Cushing syndrome, hyperaldosteronism).

**TREATMENT**

- Check the serum Na+ levels frequently while attempting to correct hypernatremia.
- Hyperoxaluria: Hyperoxaluria is usually present in patients who have nephrocalcinosis with kidney failure common in childhood. Most patients die before 30 yr. The condition often presents with stone disease producing ureteral obstruction in childhood. Type 1 can be associated with ESRD secondary to stones and interstitial deposits of calcium oxide.
- Primary hyperoxaluria type I: Less common than type I hyperoxaluria, this entity is caused by deficiencies of the hepatic glyoxylate carboligase that causes the conversion of glyoxylate to oxalate. Type I and II primary hyperoxaluria result in about the same degree of hyperoxaluria, with renal failure slightly less common in patients with type II disease. Pyridoxine is generally not effective in type II primary hyperoxaluria.

HYPERPARATHYROIDISM, UROLOGIC CONSIDERATIONS

**HYPERPARATHYROIDISM**

**DESCRIPTION**

Hyperparathyroidism can cause a variety of urologically related conditions and problems, including nephrolithiasis, hypercalciuria, nephrocalcinosis, chronic renal insufficiency, and abnormalities in renal tubular function (decreased concentrating ability). Also associated in the NEN syndrome. About 5% of new stone formers have hyperparathyroidism, whereas up to 20% of patients with hyperparathyroidism will have stones (most common calcium oxalate). These patients usually exhibit elevated serum and urine calcium with an inappropriately normal or elevated serum PTH level and elevated calcium level. Treatment is through parathyroidectomy and works for NPH when appropriate. (See also Section I: “Hyperparathyroidism and Multiple Endocrine Neoplasia.”)

**REFERENCE**

**HYPERPHOSPHATEMIA, UROLOGIC CONSIDERATIONS**

**DESCRIPTION**

Hyperphosphatemia (↑↑↑↑) can result from hyperparathyroidism, osteomalacia, medications, and chronic renal failure. Signs include muscle cramps, tetany, perioral numbness, renal osteodystrophy, and secondary hyperparathyroidism.

**TREATMENT**

Dietary restriction, stopping medications that include phosphates, and binding agents are the mainstays of therapy.

**REFERENCE**

Pate D, Beck L, Urena P, et al. Recent findings in phosphate, and binding agents are the mainstays of treatment. (See also Section I: “Hyperparathyroidism and Multiple Endocrine Neoplasia.”)

**HYPERURICOSURIA**

**DESCRIPTION**

Hyperuricosuria refers to the uric acid excretion in the urine of >860 mg/d in men and >750 mg/d in women. Uric acid, the end product of purine metabolism, is relatively insoluble in water and can lead to the formation of uric acid calculus. Overproduction and over-excretion of uric acid can be due to excess dietary intake of purine-rich foods and in patients with maladies such as (lymphoma, leukemia, hypoproliferative disease) especially after chemo or radiation induces rapid cell lysis (tumor lysis syndrome). Inherited enzyme defects can also lead to hyperuricosuria and hyperuricemia such as hypoxanthine-guanine phosphoribosyltransferase deficiency (Lesch–Nyhan syndrome) and glucose-6-phosphatase deficiency (glycogen storage disease, type I). Hyperuricosuria can be associated with hyperuricemia. The term “gouty diathesis” refers to the formation of urinary stones in persons with gout. These patients may present with other manifestations of gout such as “gouty arthritis.” These high levels of uric acid can predispose to uric acid stones that can be uric acid, calcium or a combination of both. Uric acid stones are more likely with a low urine pH (pH <6) where the solubility of uric acid is low. Allopurinol and febuxostat reduce urinary levels of uric acid, a drug metabolized via the liver and excreted in the urine of <35%.

**REFERENCE**

**HYPERKALEMIA, UROLOGIC CONSIDERATIONS**

**DESCRIPTION**

Primary hyperkalemia is the most common form of this disease, but when significant findings on evaluation are present or if the hyperkalemia is sufficiently severe to require multiple-drug therapy or requires hospitalization, a secondary cause should be sought. Common urolithiasis considerations are primary aldosteronism, congenital adrenal hyperplasia (CAH), Cushing syndrome, pheochromocytoma, and renovascular disease. Workup entails physical exam, endocrinologic workup, and imaging.

**REFERENCE**

**HYPOCALCIURIA**

**DESCRIPTION**

Calcium excretion in the urine is low. Hypocalciuria can be seen in states of low calcium intake, dietary malabsorption, or low renal calcium reabsorption. Low calcium intake is the most common cause of hypocalciuria. In the postmenopausal woman, low calcium intake may contribute to the formation of urinary stones in persons with low-renin hypertension and osteoporosis. (See also Section I: “Hypercalciuria.”)

**REFERENCE**

**HYPOGONADISM, SOCIETY DEFINITIONS**

**DESCRIPTION**

The lab diagnosis of testosterone deficiency is a challenge. The Endocrine Society defines male hypogonadism as a clinical syndrome that results from failure of the testis to produce physiologic levels of testosterone (androgen deficiency) and the normal number of spermatids caused by disruption of 1 or more levels of the hypothalamic–pituitary–gonadal (HPG) axis. Unfortunately, there is no consensus among specialists (endocrinologists, urologists, pathologist) as to what lab values defines a “low” testosterone level. Serum testosterone levels are subject to many variables including diurnal, seasonal, and age-related variations. Illness and medications (opioids, glucocorticoids), may impact testosterone levels. In addition testosterone levels impacted by alterations in sex hormone binding protein (SHBG). Further there are a variety of tests that differ in their measurement of testosterone levels leading to a wide variety of normal ranges

Endocrine Society (ES)

American Association of Clinical Endocrinologists (AACE)

**HYPOPHOSPHATEMIA**

**DESCRIPTION**

Hypophosphatemia is a poorly studied condition characterized by an excessive volume of phosphate defined in studies as <3.5–6.5 μmol/L (μmol/L). Hypophosphatemia is generally defined as a total phosphate of <1.5 mg/dL (See also Section II: “Serum Analysis, Abnormal Findings and Terminology.” and Reference II: “Serum Analysis, Technique and Normal Values.”)
Hypokalemia

Hypokalemia (K+ < 3.6 mEq/L) can result from excessive urinary losses, diarrheal disease, vomiting, diuretic therapy, or mineralocorticoid excess. Potassium intake, malabsorption, chronic diarrhea, and tubular acidosis may cause hypokalemia. Mental confusion, muscle weakness, carpopedal spasm, muscle tetany, abdominal pain, and diarrhea may occur. Hypokalemia can also result from pseudo-hypokalemia (elevated protein or lipids) or hypertonic hyponatremia (hyperglycemia). A serum K+ level of 2 mEq/L probably signifies hypokalemia.

TREATMENT

- Treat underlying cause.
- Potassium supplementation either with PO or IV therapy is recommended. Therapy is based on determination of volume status. Evaluate volume status by physical exam: HR and BP, edema, and skin turgor. Edema and skin turgor are not sensitive determinants of volume.
- Parenteral therapy: Mild 1 g IM q6h or 2 g q24h
- Severe: IV (KCl 0.25 mEq/kg/h or 20 mEq/h; IM or IV KCl 0.5 g–1 g) Tidal, IV KCI can be painful
- Slow correction: Give KCl PO: 3–4 mEq/L (mmol/L) in a 70-kg adult.

Hypomagnesemia

Hypomagnesemia (Mg < 1.5 mEq/L) results from inadequate intake, malabsorption, alcohol abuse, and hypogonadism. It may manifest as muscle weakness, or mental status changes. More severe states can produce problems at the osmotic level leading to white blood cell dysfunction or anemia.

TREATMENT

Potassium supplementation is the treatment of choice. Potassium should be administered IV in severe situations, or PO for patients with milder symptoms or hemodynamically stable states.

Hypophosphatemia

Hypophosphatemia (P < 0.7 mEq/L, mmol/L) can result from inadequate magnesium intake, malabsorption, chronic diarrhea, stress, alcoholism, and medications such as diuretics. Symptoms of hypophosphatemia include weakness, muscle cramps, muscle tetany, confusion, hallucinations, hypertension, and arrhythmias. Often accompanied by hypokalemia.

TREATMENT

- Replace with PO or IV: 10–20 mg/kg or 0.1–0.2 mEq/kg/h.
- Oral treatment: 300 mg PO or 150 mg PO q4h for patients with minimal bone disease and 2.5 g PO q4h for those with moderate/severe bone disease.

Hypophosphatemia, Urologic Considerations

Hypophosphatemia is a sodium/Na+ level of < 136 mEq/L (mmol/L). Many causes exist, but an acute cause in urology is a result of excessive nonelectrolyte irrigant absorption during endourologic procedures. As the fluid is absorbed, volume expansion and dilutional hyponatremia occur. Known as transient renal reaction (TUR) syndrome, nausea, mental confusion, and sensory disturbances are seen, and, if allowed to progress, blindness, convulsions, hypotension, coma, oliguria, and death can occur. Other causes include nephrotic syndrome, renal failure, SIADH, adrenal insufficiency, diuretics, renal tubular acidosis (RTA), GI losses, and mineralocorticoid insufficiency.

Zhao M, Li Y, Tang Y, et al. Two-stage repair with Y-shaped neo-urethra. Glansplasty and shaft skin closure and running is used to complete a 2-layer closure. A dartos incision allows for easier tubularization of the tissue and creates less scarring. The dartos incision is made with the glans incised, without entering the glans. This incision allows for easier tubularization of the tissue and creates less tension on the ventral reconstruction. Urethral plate tubulization is then performed from the end of the plate to a round urethral mound. Subepithelial running is used to complete a 2-layer layer incision. A dartos flap is then created and rotated ventrally to cover the neo-urethra. Graft is then sutured to shaft skin closure and
HYPOSADIAS, 2-STAGE REPAIR

DESCRIPTION

The basic tenet of the 2-stage hypospadias repair is to create a new urethral plate with a graft of alternative tissue in the 1st stage and then tubulize this tissue to create a neo-urethra in the 2nd stage. The main grafts for the 1st stage repair can be categorized into the following:

- Buie’s flap—paddled flaps of the dorsal hood transposed medially
- Mesh free skin graft in an onlay fashion
- Buccal mucosa free graft in an onlay fashion
- Bracka graft—a free partial thickness skin graft

The choice of graft depends on a multitude of factors including surgeon experience or preference, availability of proper skin, and history of previous surgeries.

During the 1st stage, an orthoplasty is performed and a chosen graft is placed on the ventral penis. The next stage is generally performed 6 mo or more after completion of the 1st stage where the main goal is to create a neo-urethra that corrects the hypospadias. Tubulization of local skin proceeds in a Thiersch-Duplay fashion. This step is followed by reapproximation of the glans over the newly formed urethra and 2nd layer coverage with local subcutaneous tissue or a tunica vaginalis flap. Finally, daily meatal dilation for 6 mo is recommended to completion of the 1st stage where the main goal is to create a new urethral plate that corrects the hypospadias. Tubulization of local skin proceeds in a Thiersch-Duplay fashion. This step is followed by reapproximation of the glans over the newly formed urethra and 2nd layer coverage with local subcutaneous tissue or a tunica vaginalis flap. Finally, daily meatal dilation for 6 mo is recommended to complete the procedure.

HYPOSADIAS, URETHRAL ADVANCEMENT FOR SUBGONADAL MIDSHAFT DEFECTS

DESCRIPTION

The urethral advancement and glanuloplasty (incorporated MAGPI) procedure was first described by Delclos in 1981 as an option for patients with a glanular or subcoronal hypospadias. A dorsal meatusotomy with glanuloplasty is performed to advance the neo-urethra distally. This was later modified by Zanez in 1989 for patients with a coronal or glanular hypospadias with a deep glanular groove and a fish mouth meatus as the graft approximation or “GAP procedure.” For midshaft defects, rolled mid-line tube techniques based on the initial reports of Thiersch-Duplay in the 1800s have gained renewed popularity. The Sindgraff in situ tube procedure (SITP), a variant of the Thiersch-Duplay technique, is now one of the most popular methods of hypospadias repair. Other techniques include meatal based flap procedures (eg, Mathieu) and on-lay flap repairs with native tissue or free grafts.

REFERENCE

HYSTEROCTOMY, UROLOGIC

HYPOSPADIAS, URETHRAL

DESCRIPTION

Hysterectomy is among the most common complications from TVP urethroplasty is fistula formation, which can be low as 2% in the hands of an experienced surgeon. It has proven to be a versatile procedure used in both distal and midshaft hypospadias repairs.

REFERENCE

ICE WATER TEST

DESCRIPTION

Historically performed after standard cystometry, this test may aid in differentiation of upper and lower motor neuron lesions. Ice water is rapidly instilled into the bladder and left for 1 min. If the water is ejected or the bladder pressure rapidly rises, the test is positive. Most patients with upper motor neuron/spinal lesions (eg, Parkinson, MS, CVT) have a positive test. Patients with lower motor neuron lesions almost never have a positive test.

REFERENCE

ICIQ-MULTS (INTERNATIONAL CONSULTATION ON INCONTINENCE QUESTIONNAIRE-MALE LOWER URINARY TRACT SYMPTOMS)

DESCRIPTION

The ICIQ-MULTS is a patient questionnaire used to evaluate men with LUTS and impact on quality of life. The original questionnaire comprised of 22 items and was shortened to 11 items in 2 distinct factors of voiding and incontinence. Unlike other questionnaires, such as the American Urological Association symptom score, the ICIQ-MULTS contains separate subscales for the domains of incontinence and voiding with separate consideration of frequency, nocturia, and impact on quality of life. It has been validated and reliable instrument for evaluating men with LUTS.

REFERENCE

IEF (INTERNATIONAL INDEX OF ERECTILE FUNCTION)

DESCRIPTION

The IIEF is a validated self-administered patient questionnaire used in the assessment of male sexual dysfunction. A score of 0–5 is given to each of 15 questions in 4 main sexual function domains: Erectile function, organic function, sexual desire, and intercourse satisfaction. The IIEF questionnaire is limited by a superficial assessment of psychosocial issues and other partner relationship factors which can both impact male sexual dysfunction. The abbreviated 5-item version was subsequently developed to specifically diagnose the presence and severity of erectile dysfunction.

**IMPERFORATE HYMEN**

**DESCRIPTION**

The hymen is composed of endoderm from the urogenital sinus epithelium and is located between the vaginal canal and vestibule. Normally, it opens during embryonic development. If it does not open, the hymen is called imperforate. Patients may present with hydroceles or hydropsalpinx that may obstruct the urinary tract. At puberty, females often present with primary amenorrhea and cyclic abdominal pain. Treatment is surgical if it causes symptoms.

**REFERENCES**

**IN VITRO FERTILIZATION (IVF) AND EMBRYO TRANSFER**

**DESCRIPTION**

Currently, IVF is used for women with nonremitting endometriosis, ovarian endometriosis, and in couples with male factor infertility or unexplained infertility. In most clinics, the female patient undergoes ovulation hyperstimulation with hormonal agents to increase the number of oocytes for follicle aspiration. The oocyte retrieval is performed by aspiration through the vagina with US guidance of needle placement. After aspiration of the oocytes, the eggs are incubated and placed in culture media. SpERM from the male is then integrated into the culture media and allowed to fertilize the eggs after being separated from the semen. After about 48–96 hr, 1–4 splitting embryos are placed in the uterus via transcervical injection. (See also Section II: “Assisted Reproductive Techniques (ARTs).”)

**REFERENCES**

**INCONTINENCE IMPACT QUESTIONNAIRE (IQ-7)**

**DESCRIPTION**

The underlying pathophysiology of male incontinence is related to either detrusor overactivity or external sphincter weakness, or a combination of the 2. Incontinence clamps are external devices that are used to treat male incontinence by recruiting buttow strength. They are applied externally to the penis to exert nonsurgical compression of the urethra, thereby preventing leakage of urine. The safety, efficacy, comfort, and patient satisfaction with 3 types of commercially available penile incontinence clamps (C3, U-Tex Male Adjustable Tension Band, and Cunningham clamp) has been studied in a small 12-patient trial. Results indicated that the Cunningham clamp was the most efficacious and most accepted by users. There was a concern over reduced distal blood flow velocity. None of the devices completely eliminated urine leakage when applied at a comfortable pressure. Complications of penile clamps can include edema, pain, urethral erosion, and destruction. Penile clamps should not be used for more than 4 hr at a time. (See also Section II: “Incontinence: Urinary, Anal” and Section III: “Catheter Bladders.”)

**REFERENCES**

**INCONTINENCE IMPACT QUESTIONNAIRE (IQ-7)**

**DESCRIPTION**

Short version of the IQ-7 (Incontinence Impact Questionnaire). A 7-question validated questionnaire to assess the impact of female urinary incontinence on activities of daily living. Commonly used in a prospective setting for patients undergoing anti-incontinence procedures and for research purposes.

INCONTINENCE (URINARY) WITH ORGASM (CLIMACTURIA)

INCONTINENCE (URINARY) WITH ORGASM (CLIMACTURIA)

DESCRIPTION: Urinary incontinence can be divided into 2 forms: Incontinence at penetration and incontinence during orgasm. Incontinence during orgasm has been associated with detrusor overactivity (DO), whereas female incontinence during penetration has been associated with stress incontinence. The term climacturia is used mostly when referring to male who has incontinence associated with orgasm; this condition is seen mostly after radical prostatectomy.

INDEUDS URGENCY SEVERITY SCALE (IUSS)

DESCRIPTION: A validated patient-reported questionnaire for the report of urgency severity associated with overactive bladder. This scale has been validated to capture the urgency severity per toilet void. This scale, when combined with a 24-hr diary of frequency and urge incontinence episodes, creates the Overactive Bladder Symptom Composite Score (OAB-SCS).

INFERRENTIAL ANDGMALE SYMBOLOGY

INFLAMMATORY BOWEL DISEASE, UROLOGIC CONSIDERATIONS

DESCRIPTION: Crohn disease and ulcerative colitis are inflammatory diseases of the GI tract. The inflammatory response in ulcerative colitis is mostly confined to the mucosa and submucosa, as opposed to Crohn disease, which can be transmural. These diseases can give rise to a number of urologic manifestations including fistula to the urinary tract, malabsorption syndromes leading to nephrolithiasis, and pyelonephritis gangrenous of the kidney (Image 1).

INFLAMMATORY PSEUDOTUMOR (PSEUDOSARCOMATOUS FIBROMYXOID TUMOR)

DESCRIPTION: An benign mesenchymal tumor of the bladder also referred to by many other names. Postoperative pseudosarcomatous response or lesion, spindle cell neoplasm, pseudosarcomatous or atypical fibromyxoid tumor, atypical myxofibroblastic tumor, plasma cell granuloma, nodular fasciitis, and pseudosarcomatous myxofibroblastic proliferation. The differential diagnosis of benign inflammatory pseudotumors primarily includes the spindle variant of carcinoma and sarcoma. Immunohistochemical stains are used to distinguish spindle variants of carcinoma from benign inflammatory pseudotumors. These can be seen etiologically in postpartum nonparalytic intussusception lesions or as difficult to identify submucosal lesions. These are more common in female. Management is by complete transurethral resection as inflammatory pseudotumors are benign lesions that grow slowly and do not metastasize or undergo malignant transformation.

INFUNDIBULOPELVIC DYSGENESIS

DESCRIPTION: This is an obstructive process secondary to narrowing of the infundibulopelvic system that produces various congenital anomalies such as hydrocolpos, vaginal atresia, ureteropelvic junction stenosis, and malrotation of the kidney.

INGUINAL HERNIA, ADULT UROLOGIC CONSIDERATIONS

DESCRIPTION: A direct hernia is the most common inguinal hernia in adults. It occurs when there is a protrusion of intra-abdominal contents in an area called the Hesselbach triangle (formed by the rectus abdominis muscle, inferior epigastric artery, and inguinal ligament). Unilateral bladder outlet obstruction can lead to recurrent hernia. In addition, urinary retention can occur after hernia repair. In cases of a large inguinal hernia, a portion of a distended bladder can herniate into the groin. Indirect inguinal hernias are more common in infants and children and are caused by patent processus vuvularis.

INGUINAL HERNIA, PEDIATRIC, UROLOGIC CONSIDERATIONS

DESCRIPTION: Typically, an indirect inguinal hernia is the most common type of inguinal hernia in the pediatric population. During embryologic development, the spermatic cord and testes descend through the anterior abdominal wall to the inguinal canal through the projection of the process vuvularis. If the process vuvularis persists, an indirect inguinal hernia may form and is always associated with a hydrocele.

INJECTION THERapy FOR VICESICuREtAL REFUX

DESCRIPTION
Endoscopic treatment of vesicoureteral reflux disease was first described in 1981 by Matuschek using polytetrafluoroethylene (PTFE) paste at the ureteral orifice. The primary principle behind injection therapy is to endoscopically inject a bulking agent beneath the ureteral orifice, which then helps to counter the dilating effect of voiding. The technique involves placement of the needle approximately 2 mm distal to the 6 o’clock position of the ureteral orifice. The objective is to create a “valve” like mound appearance of the ureteral orifice. Agents used for endoscopic correction of ureteral reflux should be nontoxic, cause minimal local inflammation, not migrate to other organs, and should be easy to inject. Broadly they can be categorized into two main categories: Nonoxynol and autologous. PTFE (Teflon), bovine collagen, deoxantrix hyaluronic copolymer (Deflux), and silicone are all examples of nontoxic materials. Chondrocytes, fat, collagen, and muscles are some of the autologous materials that have been used (Image Q).

REFERENCE

INSECT BITE, PENIS AND SCROTUM

DESCRIPTION
Insect bites and stings are typically acute processes with rapid onset of various symptomatologies, including pain, pruritus, signs of ecchymosis, and edema preceding exfoliating dermatitis. While this is a benign process requiring only analgesics and antihistamines for its treatment, it is important to rule out pathologic entities such as testicular torsion or cancer.

REFERENCE

INTERMITTENT HORMONAL THERAPY (IHT/INTERMITTENT ANDROGEN DEPRIVATION (IAD))

DESCRIPTION
The role of testosterone and prostate cancer has been well established; the role of androgen deprivation therapy (ADT) is to achieve serum testosterone levels similar to that induced by surgical castration. The impact of ADT in patient survival is not well known and the ideal serum testosterone level is debated. Intermittent ADT is an alternative to continuous ADT. ADT is continued until PSA reaches a nadir level. ADT is then stopped and restarted when PSA rises to pre-treatment levels. In general, intermittent ADT is better tolerated and improves overall quality of life when compared to standard ADT. There is fair evidence to recommend use of IAD instead of continuous androgen deprivation (CAD) for the treatment of men with relapsing, locally advanced, or metastatic prostate cancer who achieve a good initial response to androgen deprivation. This recommendation is based on evidence against superiority of either strategy for time-to-event outcomes and substantial decrease with IAD in exposure to androgen deprivation, resulting in less cost, inconvenience, and potential toxicity.

International Germ Cell Cancer Collaborative Group: Classification: A prognostic factor based staging system for
INTERNATIONAL PROSTATE SYMPTOM SCORE (I-PSS)

DESCRIPTION: A patient self-scoring instrument used for assessment of symptom severity in men with LUTS. The symptoms are scored from 0 (0–7), moderate (8–19), to severe (20–35); the score can also be used to measure treatment response. The I-PSS uses the same 7 questions as the AUA Symptom Index for BPH with the addition of the disease-specific QoL question (known as the bother score), scored on a scale from 0–6 points (delighted to terrible). (See Section VII: “AUAA Symptom Index for BPH” and “The I-PSS Appendix.”)

INTERSTITIAL NEPHRITIS

DESCRIPTION: Acute interstitial nephritis is most commonly caused by drugs, but autoimmune diseases (eg, lupus or sarcoidosis), Steroids are medication or treating the underlying infection or symptoms. Treatment involves stopping the offending drug or class of drugs. Nonspecific symptoms and medications such as analgesics, anticonvulsants, and antibiotics are typically caused by long-term exposure to medications such as analgesics, anticonvulsants, and Chinese herbal medications; heavy metal exposure; chronic interstitial nephritis is typically caused by chronic urinary infection or condition (eg, lupus or sarcoidosis). Steroids are controversial in treating acute interstitial nephritis but they may benefit chronic interstitial nephritis; most cases resolve spontaneously, although persistent renal dysfunction may remain.

INTRACYTOPLASMIC SPERM INJECTION (ICSI)

DESCRIPTION: An assisted reproduction technique (ART) in which a single spermatozoon is injected into the cytoplasm of an oocyte. This technique is typically utilized in males with severe oligospermia or azoospermia, as the cost is high. (See also Section D: “Assisted Reproductive Techniques (ART).”)

INTRAOPERATIVE FLOPPY IRIS SYNDROME (IFIS)

DESCRIPTION: The term of intraoperative observations of fibril iris struma that undulates and billows in response to ordinary intraocular fluid currents, a propensity for the floppy iris to prolapse toward the phacochromatization (tip and incision, and progressive intraoperative pupil constriction. This syndrome has been associated with a dislocated therapy in men with BPH, especially tamoxifen and is due to relaxation of the dilator muscle. Discontinuation of tamoxifen appears to be unpredictable and may not reliably reduce the severity. To mitigate the intraoperative problems, pharmacologic and mechanical strategies are used.

REFERENCE: Friedman AB. Tamoxifen and the intraoperative floppy iris syndrome. JAMA. 2009;301(1):244–245.

INTRAUTERINE INSEMINATION (IUI)

DESCRIPTION: An ART in which the placement of spermatozoa that have been separated from the seminal fluid are placed into the endometrial cavity through a small catheter. Typically used to treat male factor infertility caused by oligospermia and abnormalities of semen volume or viscosity. Also used with cervical stenosis or as fertility cervical tumors in femalae. (See also Section D: “Assisted Reproductive Techniques (ART).”)

INTRINSIC SPHINCTER DEFICIENCY (ISD)

DESCRIPTION: ISD is one of many components that contribute to stress urinary incontinence (SUI) and is defined as the loss of coaptation and compression of the urethra in its length. Its etiology is usually multifactorial. ISD in women may occur simultaneously with urothelial hypermobility, but should be differentiated, as the latter is an anatomic cause of SUI and not synonymous with ISD. After radical prostatectomy, ISD caused by ISD in most cases, the clinical parameters for ISD are loosely defined as a Valvular leak point pressure < 20 cm H2O or a maximal urethral closure pressure < 20 cm H2O, consensus is lacking.

CAUSES:
- Complete loss of urethral tone (catheter trauma, surgical trauma)
- Pudendal nerve dysfunction and denervation of the mid-urethral complex (external sphincter)
- Erogenic deficiency (resulting in mucosal changes effecting coaptation)
- Skene’s (anterior) dysfunction and nonsteroid skeletal muscle
- Rectal (puborectalis) and pelvic floor dysfunction
- Symmetrical injury during RP or other transurethral procedure
- Traumatic injury (pelvic fracture

TREATMENT:
- Conservative management including Kegel exercises and biofeedback
- Pelvicalyceal and needles suspension; periurethral bulking agents; synthetic (mesh) urethral sling; fascial urethral sling; artificial urinary sphincter
- Male: Male urethral artificial urinary sphincter

INVERTED PAPILLOMA, BLADDER

DESCRIPTION: An uncommon tumor of the urinary tract characterized by proliferating urothelium arranged as inverting and rests with an intact overlying urothelium. Inverted papillomas is thought to be a benign lesion but because of reports of multiplicity, recurrence, and associated TCC have been seen in the literature. Its management has been controversial (Image 1).

INVERTED PAPILLOMA, ÜRETEN RENAL PELVIS

DESCRIPTION: Consisted by most researchers to be benign, this lesion can coexist with malignant tumors. These rare, benign lesions have a presentation similar to that of other upper tract papillomas. Papillary fronds project opposite into the mucosa, appearing as smooth-surfaced, pedunculated, or sessile lesions of the urethra. There is a strong male predominance (91%). The lesions are typically small (< 3 cm), pedunculated, and project. Muscular invasion is not seen microscopically. Inverting conds and rests of urothelial cells continuous with the urothelium is a typical finding. The etiology is unknown, but probably generated by reaction to inflammation. Although benign, the lesions have a high association with urothelial carcinoma (TCC). Staging is by unnecessary for direct visualization and biopsy. Treatment has been nephroureterectomy; however, local excision is possible, but careful follow-up for other sites of cancer along the urinary tract is essential.

JOINT REPLACEMENT, UROLOGIC CONSIDERATIONS

DESCRIPTION

Originaly observed by Jarisch in 1895 and later by Herxheimer and Kraus, this reaction occurs after patients are given mercury for the treatment of syphilis. The reaction is now associated with the antimicrobial treatment of syphilitic infections such as leptospirosis, Lyme disease, tick-borne relapsing fever, and also syphilis. The reaction mostly occurs within 12–24 hr after treatment, and presents with symptoms such as rigors, malaise, headache, hypertension, and sweating. The reaction may be caused by a release of endotoxins or a transient elevation of cytokines, and it may be prevented with TNF-α antibodies or vaccine.

REFERENCE

Increased Risk of Hematogenous Total Joint Infection

Patients during the 1st 2 yr after prosthetic joint replacement

Increased Risk of Bacteremia Associated with Urologic Procedures

Any stone manipulation (includes shock-wave lithotripsy)

Any procedure with tranavascular access into urinary tract (does not include简单的 excision or percutaneous drainage procedure)

Any endoscopic procedures of upper tract (jeter and kidney)

Any procedure that includes bowel segment or transternal prostate biopsy

Any procedure with entry into the urinary tract (except for urethral catheterization) in individuals with higher risk of bacterial colonization

Indwelling catheter or indwerrant catheterization

Indwelling urethral stent

Urinary retention

History of recent recurrent urinary tract infection or prostatitis

Urinary diversion

Recommended antimicrobial regimens:

- A single-system level dose of a quinolone (eg, ciprofloxacin, 500 mg; levofloxacin, 500 mg; ofloxacin, 400 mg PO 1–2 hr preoperatively).
- Ampicillin 2 g IV (or vancomycin 1 g IV over 1–2 hr)
- A single systemic level dose of a quinolone (eg, ciprofloxacin, 400 mg; levofloxacin, 400 mg; moxifloxacin, 400 mg PO 1–2 hr preoperatively)
- Ampicillin 2 g IV (or vancomycin 1 g IV over 1–2 hr for patients allergic to ampicillin)

Recommended prophylactic agents for patients at risk for bacteremia:

- Antibiotic prophylaxis may be indicated to reduce the risk of hematogenous joint infection in patients who fit the criteria for increased risk of total joint infection and who have an increased risk of bacteremia and who meet the [7070] criteria of bacteremia.
- Antibiotic prophylaxis may be indicated to reduce the risk of other infections. Based on AUA Guidelines: Best Practice Policy Statement on Urologic Antimicrobial Prophylaxis

Increased Risk of Urinary Infection

Any procedure with entry into the urinary tract

Recommended prophylactic agents for patients at risk for urinary infection:

- Antibiotic prophylaxis may be indicated to reduce the risk of urinary infection in patients who fit the criteria for increased risk of urinary tract infection and who have an increased risk of bacteremia and who meet the [7070] criteria of bacteremia.
- Antibiotic prophylaxis may be indicated to reduce the risk of other infections. Based on AUA Guidelines: Best Practice Policy Statement on Urologic Antimicrobial Prophylaxis

TREATMENT

Recommended antimicrobial regimens:

- A single-system level dose of a quinolone (eg, ciprofloxacin, 500 mg; levofloxacin, 500 mg; ofloxacin, 400 mg PO 1–2 hr preoperatively).
- Ampicillin 2 g IV (or vancomycin 1 g IV over 1–2 hr for patients allergic to ampicillin)
- A single systemic level dose of a quinolone (eg, ciprofloxacin, 400 mg; levofloxacin, 400 mg; moxifloxacin, 400 mg PO 1–2 hr preoperatively)
- Ampicillin 2 g IV (or vancomycin 1 g IV over 1–2 hr for patients allergic to ampicillin)

For some procedures, additional or alternative agents may be considered for prophylaxis against specific organisms and/or other infections.
JUVENILE GANGRENOUS VASCULITIS, SCROTAL (PYODERMA GANGEROSUM)

DESCRIPTION

Microphallic, cryptorchidism, blindness, and deafness are also associated conditions. Testes are typically hypogonadal with anosmia, hypogonadotropic hypogonadism with anosmia, caused by failure of Kallmann syndrome.

Also called primary ciliary dyskinesia syndrome, this syndrome is characterized by situs inversus, chronic sinusitis, otitis media, airway disease, and immotile spermatozoa leading to infertility. The absence of the inner and outer sperm axoneme of cilia is the primary pathology. Most men have live but immotile spermatozoa and are infertile, whereas some have motile spermatozoa but immotile cilia. Women have decreased fertility, with <50% completing pregnancy. This is the most common of a group of inherited ciliary defects that lead to respiratory disorders called primary ciliary dyskinesias. ICSI may be used for reproduction, but genetic counseling should be offered.

Also known as hyponadism with anosmia, caused by failure of GnRH secretion by the hypothalamus, leading to testicular failure. KAL1, encoding the extracellular subunit of the GnRH receptor, is responsible for the X-linked recessive form of the disease. It is a cause of male infertility due to the defect in the short arm of the X chromosome, and has variable inheritance and penetrance. Anosmia, cleft palate, renal anomalies, microphthalmus, cryptorchidism, blindness, and deafness are also associated conditions. Notes are typically small. Delayed puberty is often an initial presenting sign.

REVIEWS

A classification system developed by Kelami to define the severity of penile curvature. The system consists of a grading system from 1–3; Grade 1, curvature of ≤90°; grade 2, curvature of 90–45°; and grade 3, >45° curvature. (See also Section I: “Penile, Curvature and/or Pain.”)

The incidence of testicular cancer is generally used as a dissociative anesthetic compound by licensed anesthesiologists. When used recreationally, it can cause hallucinations, delirium, and thought
disorders. It has been seen in increase in use in young adults. Ketamine abuse can cause urinary tract changes. These include findings of bladder trabeculation by urodynamic studies.

**REFERENCE**

**KUBRICK TEST**

**DESCRIPTION** A test designed to evaluate circulating immune factors, as an aid to diagnosing causes of infertility. Solutions of serum from both partners are combined with semen samples in a medium with an agglutinating protein. Agglutination will occur if antibodies in the serum are reactive against the sperm. Controls are usually also run with the samples to prevent errors.

**KIDNEY, METASTASIS TO**

**DESCRIPTION** Kidney metastases may present as a renal mass and grossly appear as a renal primary neoplasm. Occurs most often at autopsy, with an incidence of about 7%. They are frequently asymptomatic, but flank pain, hematuria, or hemorrhage may occur. Common primary tumors are lung (bronchogenic carcinoma most common), ovary, bowel, breast, and lymphoma. Virtually any origin is possible.

**KIDNEY, SUPERNUMERARY**

**DESCRIPTION** One of the least common genitourinary anomalies, this mass of renal tissue has no parenchymatous connection with the definitive kidney (unlike a horseshoe kidney). The supernumerary kidney is usually in a caudal position relative to the normal kidney and is rarely in a more cephalad position. The kidney is usually smaller or hypoplastic than a normal kidney and can function normally or not function at all. The ureter can insert into a normal ureter or bladder. It is usually associated with other GU anomalies, such as duplicated renal pelvis, vesicoureteral reflux, and duplicated female urethra. Treatment is unnecessary unless disease is present. (See also Section I: Renal Ectopia and Renal Ureteral Anomalies.)

**KLINFEHLER SYNDROME**

**DESCRIPTION** A syndrome characterized by small, firm testes, gynecomastia, and elevated urinary gonadotropins. It is present in 1 in 600 male births. Usually presents as incomplete virilization, infertility, or rarely as male pseudohyphardrophtyndrom. Menstrual irregularity and low bone mineral density (BMD) are associated. A testicular biopsy usually shows sclerosis of tubules. The condition is caused by a nondisjunction of the melotic chromosome, resulting in XXY karyotype and its variants. FSH is markedly elevated. Azoospermia is traditionally described on semen analysis, but recent series indicate that sperm can be found in over 50% of men with Klinefelter syndrome; thus, these men are not always sterile. Recent evidence suggests that children with Klinefelter syndrome are born with spermatogonia and lose large numbers of germ cells during puberty. No treatment can improve spermatogenesis. (See also Section II: “XY Syndrome.”)

**KLIPPEL–TRENAUNAY–WEBER SYNDROME**

**DESCRIPTION** Klippel–Trenaunay–Weber syndrome was first described by French physicians in 1900. It consists of cutaneous vascular malformations in combination with soft tissue and bone hypertrophy. The defects are present at birth and most commonly involve the lower extremities. The vascular lesions may develop before or after birth. A study of 214 patients by Hussain et al., 30% had genital cutaneous involvement. Of these patients, 36% developed intractable bleeding. Surgical excision of these vascular malformations was associated with significant blood loss.

**KOYLE STENT**

**DESCRIPTION** The Koyle stent (Cook Medical Inc., Bloomington, IN, USA) is used for stenting the urethra after hypospadias repair. It has an 8 Fr circumference in the fossa navicularis to minimize distal meatal or urethral ischemia while providing excess tubing externally to allow drainage into a 2nd or outside stent while keeping the inside stent dry to allow healing.

**KRUGER STRICT SPERM MORPHOLOGY**

**DESCRIPTION** Some fertility experts use the test to decide between intrauterine insemination (IUI) and in vitro fertilization (IVF) although the test is controversial. This test examines sperm morphology more in-depth than the standard WHO method. Finally sediment sperm are smeared on a slide and stained. Sperm are judged as normal based on the following criteria:

- Head must be oval in shape with smooth contours, 4.5–6 μm in length and 2.5–3.5 μm wide with the acrosome taking up 40–70% of the head.
- Neck and mid-piece must have no abnormalities and a cytoplasmic droplet (a remnant from sperm production) if present must not be larger than 1/2 the size of the head.
- Tail must not be coiled or bent and should not have a droplet at the end.

After 200 individual sperm are counted at 1,000 X, the percent normal forms are calculated. The Kruger prognosis is based on the following scale:

- ≤15% normal
- 15–14% normal
- Normal range: Good prognosis
- Sub optimal range: Prognosis is fair to good, however, the lower the percent normal the lower the chance of successful fertilization
- 0–4% normal
- Poor prognosis: IVF usually needed

LABIAL ADHESIONS AND FUSION

DESCRIPTION
Complete (fusion) or partial adhesion of labia minora. Low estrogen levels contribute to a thin atrophic lining, which is easily denuded and later heals with adhesions. The condition is acquired, not born at birth, and occurs in prepubertal girls and postmenopausal women. focal coiling as age, trauma, hormones, and sexual abuse may be inciting factors. It may cause voiding dysfunction in some cases, with resulting hydronephroplasty.

SYNONYMS
Acquired postinflammatory cohesion of the labia minora
Vulvar fusion
Synchiae of the vulva

TREATMENT
- Conjoined labial frenum locally applied
- Surgical treatment for severe cases

REFERENCE

LACTATE DEHYDROGENASE (LDH), UROLOGIC CONSIDERATIONS
DESCRIPTION
LDH is a cellular enzyme useful in monitoring the treatment of GCT. It tends to have low specificity (further impaired in smokers), and therefore must be correlated with other clinical markers in the evaluation of male germ cell tumors.

CONSIDERATIONS
LAPIDES CLASSIFICATION OF VOIDING DYSFUNCTION
DESCRIPTION
A historical system for categorizing neurogenic voiding dysfunction into 5 areas:
- Sensory neurogenic bladder: Intermittent altered sensation during bladder filling; delayed bladder sensation on voiding
- Motor neurogenic bladder: Destruction of parasympathetic motor innervation to the bladder results in painful overdistension initially and inability to initiate and maintain micturition. Common processes include diabetes mellitus, tobin disorders, and perineum anemia.
- Parasympathetic bladder: Intravesical and interstitial cystitis: can be present neonatally in up to 25% of males.
- Reflex neurogenic bladder: Complete interruption of sensory and motor pathways between the sacral spinal cord and brainstorm leads to lack of bladder sensation and inability to voluntarily micturate. Common processes include trauma and transverse myelitis.
- Autonomous neurogenic bladder: Complete motor and sensory separation from the sacral spinal cord leads to inability to voluntarily micturate and lack of reflex bladder activity and bladder sensation.

REFERENCE

LASER TECHNOLOGIES AND UROLOGIC APPLICATIONS
DESCRIPTION
The use of laser (short for “light amplification by stimulated emission of radiation”) in urology has gained widespread acceptance. The primary mechanism of laser operating systems is based on the process of stimulated emission of radiation where excited electrons rapidly decay and emit photon energy, which leaves a resonator cavity as a coherent laser beam. Lasers impart 4 different effects: Thermal, mechanical, photomechanical, and tissue welding effects. The thermal effect is most commonly employed. The laser light energy is absorbed and transformed into heat. The heat denatures proteins at 42–45°C, shrinks arteries and veins at 70–90°C, and coagulates the tissue at 100°C. After water has evaporated from the tissue, the temperature rapidly rises, with carbonization at 250°C, and vaporization occurs at 300°C. Mechanical effects are used to create a plasma bubble that expands rapidly to disrupt stones. Photomechanical effects involve laser activation of specific drugs or compounds taken up by the tissue and tissue welding relies upon collagen cross-linking with materials activated by lasers of specific wavelength.

CONDITIONS such as nephrolithiasis, benign prostatic obstruction (BPO), bladder cancer, kidney cancer, urethral cancer, and stricture disease have all been treated by laser therapy. Some modern laser systems include potassium titanyl phosphate (KTP), holmium:yttrium-aluminum-garnet (Ho:YAG), and semiconductor diode lasers. The frequency-doubled, short-pulse Nd:YAG (FREDDY) laser is a double-pulse Nd:YAG, Ho:YAG, KTP:YAG, semiconductor diode, or CO2.

The laser operating systems are based on the process of stimulated emission of radiation: “Stimulated emission of radiation” is derived from the Greek word “stima,” meaning “to excite.” The laser operating systems is based on the process of stimulated emission of radiation: “Stimulated emission of radiation” is derived from the Greek word “stima,” meaning “to excite.” The thermal effect is most commonly employed. Photomechanical effects involve laser activation of specific drugs or compounds taken up by the tissue and tissue welding relies upon collagen cross-linking with materials activated by lasers of specific wavelength.

LAURENCE–MOON–BARDET–BIEDL SYNDROME
DESCRIPTION
This autosomal recessive disease was initially described in 1860 by Laurence–Moon and received a more exact description in 1920 by Bardet–Biedl. A wide variety of manifestations include retinal pigmentary dystrophy (previously termed retinitis pigmentosa), postnatal polydactyly, obesity, mental retardation, and hypogonadism. More recently, renal abnormalities have been described, including chronic glomerulonephritis, characteristic cystic tubular disease, lower urinary tract malformations, and defects of tubular concentrating ability. Renal failure is the major cause of morbidity and early mortality. Underdiagnosed or overlooked cases can be present neutronally in 1 to 2% of males.

SYNONYMS
- Laurence–Moon syndrome: More general, including all of the above description
- Laurence–Moon–Bardet–Biedl syndrome: Much rarer; differs with the above description, including progressive spastic paraparesis and distal muscle weakness but without proptosis

REFERENCES
Bakal A, Winter AR, H terms. Renal failure is the major cause of morbidity and early mortality. Underdiagnosed or overlooked cases can be present neutronally in 1 to 2% of males.

LAZY BLADDER SYNDROME (NURSE’S BLADDER)
DESCRIPTION
First described by Spawin in 1962, this condition occurs when children exhibit hold behavior and void infrequently. Thought to be caused by the continued voluntary suppression of the normal desire to void, it is more common in girls. Patients are prone to develop UTIs due to urinary stasis and often have problems with constipation. Some patients have overflow or stress incontinence. The VCGU shows a large smooth-walled bladder, and US of the upper tract is usually normal. Voiding studies show large bladders with decreased sensation during bladder filling, low pressures, and long postvoid residuals. Timed voiding studies, antibiotic suppression,
LeBAG NEobladder

**DESCRIPTION** This is a modification of the classic orthotopic neobladder, which uses only 1 ileal limb instead of 2. The detubularized colon and a single segment of ileum can be joined using metal staples to create a broad intestinal plate, which is then converted into a pouch with a ureterointestinal and urethral anastomosis.

**LeDuc Ureteral Anastomosis**

**DESCRIPTION** The end of the small bowel segment is opened 4–5 cm and a longitudinal incision is made in the mucosa, which is then raised. At the distal end of this incision, a hole is made through the wall of the ureter. The ureter is pulled through this opening and laid in the mucosal incision. The mucosa is then sutured to the side of the ureter.

**LEIGYOMATOSIS, HEREDITARY**

**DESCRIPTION** Familial cancer syndrome of a urothelial tract and skin. The syndrome may result from BEjemmal syndrome, a germline or somatic event that leads to loss of function of the FBEM2 gene. Familial cancer syndrome of the urothelial tract includes a renal tumor, skin lesions, and dysplasia of the eye, skin, and testis. Lesions are usually seen in women 20–35 yo. Given their aggressive nature, the prompt surgical resection of renal tumors is recommended. (See also Section II: “Renal Neoplasms.”)

**LEOPARD SYNDROME**

**DESCRIPTION** An autosomal dominant condition similar to Noonan syndrome, except for multiple lentigines (melanin pigment accumulation within the dermis and epidermis). LEOPARD syndrome is the mnemonic for lentigines, eye anomalies, cardiac anomalies, pericardial effusions, adenopathy, renal anomalies, and dental abnormalities. Prominent lentigines in children, including a small penis and small, often undescended testicles, is the most common association. Hypoplastic and delayed puberty may also be found.

**SYNONYMS**

- Multiple lentigines
- Progressive cardiomyopathy

**TREATMENT** Orthoptics, repair of hypoplastic

**LERICHE SYNDROME**

**DESCRIPTION** Described in 1923 as symptoms characteristic of thrombotic occlusion of the terminal aorta, this syndrome is caused by atherosclerosis of the arterial wall, with thrombus and gradual occlusion. Symptoms include fatigue of both lower limbs, symmetrical atrophy of lower extremities, pallor of legs, and an inability to maintain a stable position due to inadequate arterial flow to the penis (hypogastric arterial obstruction). Gradual occlusion allows for collateral circulation; therefore, acute symptoms are unlikely.

**SYNONYM** Gradual thrombotic obliteration of the abdominal aorta and iliac arteries

**TREATMENT** Bypass graft from the aorta to iliac or common femoral arteries

LEUKOPLAKIA, PENIS

TREATMENT
- If the lesion is the isolated site of relapse, local irradiation (up to 20 Gy) to both testes and reinstitution of systemic chemotherapy can be curative.
- Therapy can cause irreversible damage to seminiferous tubules and Leydig cells.
- Patients can develop hypergonadotropic hypogonadism and low testosterone with azoospermia.

REFERENCES

LEUKOPLAKIA, PENIS

DESCRIPTION
Saffory or whitish plaques with hyperkeratosis, papulexerosis, and hypertrophy of the squamous intra-epithelium, with edema and papillary proliferation. The condition often involves the penile mucosa and has been associated with in situ squamous cell carcinoma (SCC) and verrucous carcinoma.

TREATMENT
- Eliminate chronic irritation
- Circumcision
- Surgical excision with periodic biopsy of incompletely excised lesions

REFERENCES

LEUKORRHEA

DESCRIPTION
Generally refers to nonspecific, mucous, white, or yellowish vaginal discharge in the absence of any pathological cause. The quantity and quality vary among individuals, and mild irritative symptoms can be common. Leukorrhea is also seen during infancy secondary to maternal estrogens, as well as during puberty secondary to estrogen surge. Leukorrhea is at all that is necessary if the cervical and vaginal exam is normal, vaginal pH is normal (<4.5), and there are normal findings on microscopic and a negative amine test. (See also Section II: “Vaginosis”; Section III: “Normal findings on microscopy and a negative amine test.”)

REFERENCES

LICHEN NITIDUS, PENIS

DESCRIPTION
An uncommon chronic inflammation appearing as flesh-colored papules with sharp demarcations and flat, shiny, and slightly elevated surfaces. The etiology is unknown, but it is believed to be a variant of lichen planus. Histologically, lichenoides, histiocytes, and melanophages form a ball-like structure covered by epidermis with a characteristic claw-like projection of the rete ridges. The condition is usually asymptomatic.

TREATMENT
- • Step healing is common
- Oral histamines
- Topical antivirals and topical corticosteroids may be helpful

REFERENCE

LICHEN PLANUS, PENIS

DESCRIPTION
An uncommon pruritic lichenoid dermatologic eruption that occurs almost exclusively on the penile glans, but may also involve the shaft, scrotum, and inner surfaces of the thighs. It is characterized by patches of violaceous, flat-topped papules. Histologically, there can be degeneration of the basal cell layer keratinocytes and dense infiltration of lymphocytes in the upper dermis hugging the epidermis. Multiple lesions occur and can ulcerate. Differential diagnoses include secondary syphilis, bowel disease, psoriasis, lichen sclerosus et atrophicus, and squamous cell carcinoma (SCC). There is no specific treatment; symptomatic relief is obtained through antihistamines, zastatic, and topical lotions.

REFERENCES

LICHEN SCLEROSIS ET ATROPHICUS

DESCRIPTION
An uncommon cutaneous disorder with a female predominance. Early lesions are characterized as white macules, which may coalesce into patches, or flat, white, or pink-depressed papules and plaques. Confluence of the papules and marked hyperkeratosis and atrophy may develop. Extra-genital areas (eg, arms, shoulders, trunk, neck, and face) are less commonly affected in men. Dysuria, pruritus, and pain are associated with the disease process. Squamous cell carcinoma (SCC) has been reported to occur.

SYNONYMS
- Lichen sclerosus
- Lichen sclerosus et atrophicus
- The late stage evolves into balanitis xerotica obliterans

TREATMENT
- Circumcision
- Topical treatments for nongenital areas

REFERENCES

LICHEN SIMPLEX CHRONICUS

DESCRIPTION
Localized chronic pruritus with patches of dermographism, resulting from chronic scratching/scratching. Common sites are the periumen, thigh, scrotum, and vulva. The lesions appear as multiple oval plaques that become thickened and scaly. There is a whitish gray discoloration caused by lichenification and hyperkeratosis. The skin may become more susceptible to secondary infection and allergic contact dermatitis. Etiologies include irritants (irritant and allergic), infection, and underlying dermatitis. Microscopically, the lesions resemble chronic dermatitis with hyperkeratosis and parakeratosis. Diagnosis is usually clinical, but biopsy may be necessary.

SYNONYM
Circumscibed neurodermatitis

TREATMENT
- • Break the scratch itch cycle
- Stop all irritants
- Sit baths or soaks
- Open wet compresses to affected areas
- Systemic antihistamines and/or sedating medications may be necessary to lessen the itching
- Topical and occasionally systemic steroids are necessary

REFERENCES

LICHEN–GREGOIR URETERAL REIMPLANTATION

DESCRIPTION
This extravesical, less invasive repair does not disrupt the ureteral trigone continuity. A 4–5 cm trough is created by dissecting the mucosa of the mucosa, and the mobilized ureter is placed in the trough with the detrusor closed over it.

REFERENCE

LIDDLE’S SYNDROME

DESCRIPTION
Liddle’s syndrome is an autosomal dominant disorder of the sodium channels of the collecting duct. Mutations in the epithelial sodium channels in the kidney result in increased activity and severe hypertension is typically the result. Features of hypokalemia and metabolic alkalosis can also occur mimicking primary hyperaldosteronism. Treatment generally focuses on a low salt diet in conjunction with a potassium sparing diuretic.

REFERENCES
LIFE EXPECTANCY, UROLOGIC CONSIDERATIONS

DESCRIPTION: Life expectancy is commonly used by urologists when determining therapy for localized prostate cancer, as age may influence choice of treatment.

REFERENCE

LIPOMA, BLADDER

DESCRIPTION: Bladder lipoma is a rare entity. It can be associated with a pelvic lipoma, and has been reported to cause bladder outlet obstruction. A capsule surrounds the homogenous, sharply margined fat, if it is benign and must be distinguished from liposarcoma, angiolipoma, and cystic teratoma, usually by CT. Treatment is by surveillance, unless otherwise abnormal in children.

REFERENCE

LIPOMA, SPERMATIC CORD

DESCRIPTION: Foreign infiltrated preperitoneal fat that can project down the cord. Accounts for up to 90% of spermatic cord tumors and is most commonly seen in adults. Histologically, it contains adipose, fibroadipose, fibromyxoid, myxoid liposarcoma, and myxoid liposarcoma. The lesion can present as a mass, and must be distinguished from adenomatosus tumor, leiomyoma, fibroma, lipoma, leiomyosarcoma, and fibrosarcoma.

See also Section I: “Spermatic Cord Mass.” Complete excision at time of surgery is recommended.

REFERENCE

LIPOMATOSIS, PELVIC

DESCRIPTION: Pelvic lipomatosis was first described in 1939 as an outgrowth of fat in the perineal and perirectal regions that can cause compression of the lower urinary tract and lead to urgency. Rare disease found primarily in men in the 3rd-6th decades of life. Approximately 2/3 of patients are African American, with an 18:1 male to female ratio. Lipomatous tissue is composed of mature adipose and may be associated with inflammation. Histopathologically, it is found to be dense, vascular, unencapsulated lipomatous tissue that commonly envelops the pelvic viscera. It differs from a simple lipoma by the fact that it does not arise from a single focus, is not encapsulated, and does not expand centrifugally. Clinical features vary from urinary frequency to constipation. Pelvic lipomatosis has been associated with a higher incidence of hypertension. On a plain abdominal r-ray, it presents with radiolucency of the pelvic perivisceral area. Other radiographic signs include an elongation and elevation of the bladder, and the rectum and sigmoid colon. There is widening of the rectovesical space and increased lucency of the pelvic sidewalls. On computed tomography, a full bladder has an abnormal shape (banana shape) and position (superiorly as well as anteriorly). Cystoscopy should be performed, as there are reports of associated cystitis glandularis. Surgical removal of the lipomatosis may be feasible in selected few patients. For those patients with obstructive uropathy, treatment options include ureteral stenting, nephrostomy tubes, ureteral reimplantation, or urinary diversion. Pelvic lipomatosis is done with caution as the normal anatomic planes are disrupted by the infiltrating fat.

REFERENCE

LIPOMENINGOCELE, UROLOGIC CONSIDERATIONS

DESCRIPTION: A meningocele associated with an underlying lipoma. This condition belongs to the family of occult spinal lipomas in which the formation of the spinal column is affected but does not result in an open vertebral canal. Outward signs and symptoms may be subtle, and the neurologic exam may be normal. As children get older, they may present with dryness, recurrent UTIs, or fecal soiling. In children incontinence (incontinence after initial period of normal. As children get older, they may present with features vary from urinary frequency to constipation. Pelvic lipomatosis has been associated with a higher incidence of hypertension. On a plain abdominal r-ray, it presents with radiolucency of the pelvic perivisceral area. Other radiographic signs include an elongation and elevation of the bladder, and the rectum and sigmoid colon. REFERENCE

LIVER METASTASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION: The liver is a primary site for many malignant neoplasms, including those arising in the G1 tract. Stomachal carcinoma (TCC), renal cell carcinoma (RCC) and testicular carcinoma may spread to the liver, but metastasis is most commonly seen in prostate cancer. In addition to bone pain and spinal cord compression, liver metastasis can be very painful. A liver lesion itself should not affect the urinary tract, but extensive disease may be reflected in increased bilirubin and abnormal liver function studies on urine analysis.

TREATMENT
• Evaluate and treat primary tumor.
• Segmental resection or lobar ablative therapies may be appropriate (Image 9).

REFERENCE

LOBAR NEPHRONIA

DESCRIPTION: A renal mass caused by acute focal infection without liquefaction. Clinical characteristics most frequently encountered are fever, flank pain, or back pain. Uroradiographic findings in this condition can mimic a renal abscess or neoplasm. Bacterial infection (e.g., K. pneumoniae, Proteus, Pseudomonas) and Candida albicans are common causes. Appropriate medical treatment will cause the infected mass to disappear, but scarring may occur. (See also Section I: “Pyelonephritis, Acute, AAM.”)

SYNONYMS
Acute focal bacterial nephritis.

TREATMENT
• IV antibiotics
• Radiologic surveillance: CT or US

REFERENCE

LORD PROCEDURE (HYDROCELECTOMY)

DESCRIPTION: During the Lord procedure for hydrocelectomy, radical sutures are used to gather the sac around the posterior aspect of the testis and epididymis. It was initially developed in 1964 to reduce the size of postoperative hematoxia formation after hydrocelectomy. This technique does not require dissection of the hydrocele sac and therefore can be relatively bloodless. Generally this technique is recommended for thin-walled hydroceles.

REFERENCE

719
LOWE SYNDROME

DESCRIPTION Lowencephalencephalodysplasia is a rare autosomal recessive condition characterized by mental retardation, microcephaly, and a characteristic facial appearance. It is caused by mutations in the P Tillion gene on chromosome 11q23.3.

SYNONYMS P Tillion syndrome, Lowe syndrome

LYMPHANGIOMA, BLADDER

DESCRIPTION Bladder lymphangioma is a rare, benign, lymphatic malformation that presents as a solitary, encapsulated mass. It is often associated with urothelial abnormalities and may cause symptoms such as hematuria or urinary tract infections.

LYMPHANGIOGRAM, PEDAL

DESCRIPTION Pedal lymphangiogram is a radiographic examination used to visualize the lymphatic system. It involves the injection of contrast material into the lymphatic system and imaging the resulting lymphatic vessels to assess their function and structure.

LYMPHANGIOGRAM, SCROTAL

DESCRIPTION Scrotal lymphangiogram is a diagnostic procedure used to evaluate the lymphatic vessels in the scrotum. It involves injecting contrast material into the scrotal lymphatic vessels and imaging the resulting changes to assess for abnormalities.

LYMPHATIC ASCITES

DESCRIPTION Lymphatic ascites is a rare complication of lymphatic obstruction, typically seen in patients with lymphatic malformations or lymphedema. It is characterized by the accumulation of lymphatic fluid in the peritoneal cavity, leading to ascites.

LYMPHOPHAGNIOLUINOMA VENEREUM

DESCRIPTION Lymphogranuloma venereum (LGV) is a sexually transmitted infection caused by Treponema pallidum subspecies pallidum. It is typically transmitted through sexual intercourse and affects the genital tract, anus, rectum, and lymph nodes.

LYMPHOPHAGNIOLUINOMA, RETROPÉRITONEAL

DESCRIPTION Retroperitoneal lymphangioma is a rare, benign lymphatic malformation that can occur anywhere in the retroperitoneal space. It is typically asymptomatic but can cause symptoms such as pain, swelling, or palpable masses.

including HIV should be considered. Fluctuant buboes can be aspirated to reduce morbidity.

**TREATMENT**
- Doxycycline is the treatment of choice and can be aspirated to reduce morbidity.
- Alternatives and should be used for at least 3 wk.
- They involve chemotherapy for primary lesions combined with local low-dose radiation.

**REFERENCE**

---

**LYMPHOMA, UROLOGIC CONSIDERATIONS**

**DESCRIPTION**
- Lymphoma can involve any part of the urinary tract, but is more commonly seen in the testicle and kidney.
- Lymphoma is often a cause of testicular cancer in older men. It may be a local tumor growth or a late manifestation of widespread disease.

**TREATMENT**
- Primary bladder lymphoma occurs almost exclusively in hemophiles. Lesions may be sessile or pedunculated and should be differentiated from chronic inflammatory bladder inflammation, small cell carcinoma, and a rare entity called lymphoma-like carcinoma.
- Prostate lymphoma typically presents in older men, with symptoms of bladder outlet obstruction. PSA is rarely elevated. This is usually a manifestation of systemic disease, with primary prostate disease rare.
- The differential diagnosis includes chronic inflammatory bladder inflammation, small cell carcinoma, and a rare entity called lymphoma-like carcinoma.
- Treatment: The differential diagnosis includes chronic inflammatory bladder inflammation, small cell carcinoma, and a rare entity called lymphoma-like carcinoma.

**REFERENCE**

---

**LYMPHORETICULAR MALIGNANT NEOPLASM, PENIS**

**DESCRIPTION**
- Rarely, lymphoreticular malignancies (eg, leukemia) may infiltrate the penis. Primary disease is rare, and a search for systemic disease is mandatory. The most common presentation is priapism, a painful prolonged erection. Treatment involves chemotherapy for primary lesions with focal low-dose radiation.

**REFERENCE**

---

**LYMPHOVASCULAR INVASION (LV), UROLOGIC CONSIDERATIONS**

**DESCRIPTION**
LV1 describes an important feature for many aspects of urologic oncology, because it is an adverse prognostic indicator in urothelial carcinoma of the bladder and upper tracts, prostate cancer, and testicular cancer. In upper tract UCC, it has been found to be an independent prognostic factor for disease-specific survival. In noninvasive bladder cancer, it is a relative indication for early cystectomy. In testicular cancer, it is a risk factor for reinterventional and/or systemic failure.

**REFERENCE**

---

**LYNCH SYNDROME**

**DESCRIPTION**
An autosomal dominant genetic syndrome caused by mutations in mismatch repair enzymes, most commonly MSH2 and MLH1. This creates DNA MSI (microsatellite instability) and increases the risk of colon and endometrial malignancy. An increased risk of upper tract urothelial carcinoma (UTUC) is also observed and these cases can be successfully managed with ureteroscopic treatment/surveillance. In addition, these patients are at increased risk of developing bladder lesions as well.

**SYNONYMS**
- Nevoid polyposis colorectal cancer
- Nevoid site-specific colon cancer

**TREATMENT**
- Screening for mutation can be performed via genetic testing.
- If screening is positive, surveillance colonoscopy is recommended.
- Netherlands Surveillance Protocol for specific individuals (includes regimented colonoscopies, urine cytology, upper endoscopy, and US of the endometrium).

**REFERENCE**

---

**MACRO-ORCHIDISM (MO)**

**DESCRIPTION**
Macro-orchidism (MO) is an increase of testicular volume, up to 25 mL, seen in the adult male. It is frequently associated with mental retardation with fragile X-chromosome. MO has also been described in association with bilateral testicular tumors, idiopathic precocious puberty, juvenile hypothyroidism, and, more rarely, with congenital testicular cysts (cystic testicular dysplasia). Management of MO must be conservative in all cases, and testicular biopsy must only be performed to diagnose leukemic infiltrate, carcinoma in situ, or as part of a fertility workup. MO may be related pathogenetically to some hormonal regulation mechanism or to higher seminiferous tubule sensitivity to FSH.

**REFERENCE**

---

**MAG 3 RENAL SCAN**

**DESCRIPTION**
A nuclear medicine scan is used to evaluate renal function and the presence of obstruction. MAG3 (technetium-99m mercaptoacetyltriglycine) is a renal isotope secreted by the renal tubules. Multiple images are taken over time to give anatomic details, including scanning and function of the kidney. A split differential function between the 2 kidneys is obtained. Commonly, isosulfan blue is administered to induce diuresis, and the time for the kidney to clear 1/2 of the tracer is calculated (t1/2). A 1-2 of 0–10 min indicates nonobstructive drainage, >10 min is indeterminate, and >20 min is consistent with obstruction.

**REFERENCE**

---

**MACRO HYPOSPADIAS REPAIR**

**DESCRIPTION**
The median advancement and glansplasty procedure (MAG) was first described by Budzik in 1981. After a circumferential subcoronal incision, the bridge of tissue immediately distal and dorsal to the meatus is split in a vertical fashion and...
closed in a horizontal orientation (Heineke–Mikulicz closure). The ventral edge of the new meatal opening is pulled up, and the flap is reapproximated ventrally which, in effect, advances the meatus.

**REFERENCE**

**MAINZ I, II, III POUCH URINARY DIVERSION**
**DESCRIPTION**
The MAINZ pouch (coelocystoanal) is an orthotopic pouch created by opening theoreum and 2 limbs of distal ileum, the Wigs are then sutured to create a broad intestinal plate. After a tunneled enterococcal anastomosis is made, the orificial portion of the plate is anastomosed to the male urethral stump and the plate is closed into a sphere. The MAINZ II (urogenital pouch) is an augmented valved intestine created by making a 10–12 cm rectosigmoid opening. The orificial column is configured into a U shape, and the medial plate is closed. Urines are implanted through submucosal tunnels. After securing the apex of the pouch to the sacral promontory, the remaining plate is closed. The MAINZ III is a continent cutaneous diversion created by making a 10–12 cm rectosigmoid opening. The orificial column is a transverse-descending colon pouch (transverse ascending color pouch or transverse-descending color pouch) with the pelvis. The different segment created from a transposed bowel segment embedded in the pouch wall.

**REFERENCE**

**MALACOPLAKIA, GENITOURINARY**
**DESCRIPTION**
Malacoplakia, derived from the Greek term for soft plaque, is a chronic inflammatory disease, the etiology of which remains obscure. It appears related to an underlying infectious process. It has a very low incidence and affects primarily the GU tract. The diagnosis is made by biopsy. The pathologic specimens typical of malacoplakia consist of large histiocytes known as von Hansemann cells and intracytoplasmic inclusions known as Michaelis–Gutmann bodies. The goal of treatment is to stabilize the disease process by controlling UTI. (Image 40).

**REFERENCES**

**MALARIA (BLACK WATER FEVER), UROLOGIC CONSIDERATIONS**
**DESCRIPTION**
The preclinical Plasmodium parasitism in the parotid responsible for malaria. From a urologic perspective, malaria can cause hemorrhagic gastroenteritis. Treatment includes full-dose antimalarials with supportive care. Acute renal tubular necrosis can occur if the infection is left untreated and some patients with chronic malaria develop nephritic syndrome. (See Section II: “Black Water Fever.”)

**REFERENCE**

**MALE SEXUAL FUNCTION SCALE**
**DESCRIPTION**
An 8-question sexual health inventory completed by the patient, which assesses core components of male sexual function including desire, erection, ejaculation, and satisfaction. The scale is meant to screen for sexual health in both the primary care and urogynecologic practice settings.

**REFERENCE**

**MALE SEXUAL HEALTH QUESTIONNAIRE (MSHQ) AND THE MSHQ SHORT FORM**
**DESCRIPTION**
A patient self-administered test developed in 2004, the MSHQ is a 25-question questionnaire that evaluates sexual function and satisfaction in older men with LUTS. It provides more in-depth assessment of ejaculatory functioning than previous measures of sexual dysfunction, namely the International Index of Erectile Function (IIEF). A 4-item version is called the MSHQ short form, and both forms can be used in research settings as well as in clinical practice to assess ejaculatory dysfunction. (See Section VII: “Reference Tables: Male sexual health questionnaire, Short Form.”)

**REFERENCE**

**MALROTATED KIDNEY/RENAL MALROTATION**
**DESCRIPTION**
Malrotated kidney occurs when the kidney does not rotate 90° medially during fetal development. As a result, the renal pelvis, which normally lies medial to the parenchyma, is located anterior to the parenchyma. Often a malrotated kidney is an incidental finding. Malrotation makes the kidney more susceptible to trauma, and is also commonly observed in ectopic kidneys. (See also Section I: “Renal Ectopia.”) (Image 45)

**REFERENCE**

**MARSHALL–MARCHETTI–KRANTZ (MMK) CYSTOURETHEROPEXY**
**DESCRIPTION**
A historical procedure used to repair urinary-vaginal fistulae. The flap is a well-vascularized fat pad from the labia majora and receives its blood supply from the branches of the pudendal artery. It is tunneled beneath the labia minora into the vaginal lumen, where it is used as a peritoneal graft fixated with the site of the fistula repair. It serves as a well-vascularized barrier between two bariatric layers to prevent recurrent fistula formation.

**SYNONYMS**
- Martius labial pedicle graft
- Martius labial fat pad
- Martius flap

**REFERENCE**

**MATHIEU HYPOSPADIAS REPAIR**
**DESCRIPTION**
A ventral flap is mobilized based on the dorsal blood supply, and it is transposed over the urethral plate to advance the meatus. The lateral wings of the flaps are reapproximated over the repair.

**REFERENCE**

**MATURATION ARREST**
**DESCRIPTION**
The term maturation arrest has been used to describe testicular biopsies in cases of infertility. A 2-forms of maturation arrest have been described: Spermatogenic arrest and spermatocytic (meliotic) arrest. The arrest is most frequently observed at the primary spermatocyte level. Reversible arrest at this level can be due to heat, infections, and hormonal and nutritional factors. Irreversible arrest at this level occurs at the primary spermatocyte or spermatid level and has a genetic origin due to chromosomal anomalies. The dysfunction occurs in somatic and germ cells.

**REFERENCE**
**MAXIMUM ANDROGEN BLOCKADE (MAB)/COMBINED HORMONAL THERAPY (CHT)**

**DESCRIPTION**

The main concept behind maximum androgen blockade (MAB), sometimes referred to as combined hormonal therapy (CHT) or total androgen blockade is that by adding an antiandrogen in conjunction with surgical castration or LHRH agonist therapy, urologists can minimize the effects of any extragonadal sources of androgen production similar to what is observed in the prepubertal child. This strategy was traditionally noted to be the adrenal gland. Studies in both being conflicting with some showing prolonged survival in patients treated with MAB with advanced prostate cancer and others demonstrating no significant difference. In a large meta-analysis published by the Prostate Cancer Trialists’ Collaborative group, a nonsignificant 1.8% 5-yr survival was found in the MAB group. This study included 27 randomized trials and over 8,200 patients.

Short-term MAB (1–2 wk) is generally agreed to in men with newly diagnosed metastatic disease when starting androgen deprivation with an LHRH analog to block the so-called “false” reaction. Most RDS trials that combine radiation therapy and external beam radiation therapy for intermediate- and high-risk disease are performed using MAB (9–10 mo to 2–3 yr based on the risk and protocol).

**REFERENCES**

**MAYOR–ROKITANSKY–KUSTER–HAUSER SYNDROME (ROKITANSKY–KUSTER–HAUSER SYNDROME)**

**DESCRIPTION**

A congenital absence of the vagina. The uterus is either absent or absent. The diagnosis is usually made when amenorrhea is noted in a normal pubertal XX person with a female phenotype. Renal and skeletal anomalies are a common association. The defect involves mesodermal development and the mesecephalic kidney, the latter resulting in abnormalities in the paramesonephric (uterus and vagina) and in the metanephric kidney.

**REFERENCES**

**MAYO CLINIC GRADING SYSTEM FOR PROSTATE CANCER**

**DESCRIPTION**

A grading system for prostate cancer that uses not only assessment of glandular architecture similar to Gleason’s grading system, but also histologic criteria. Grading is done on a scale of 1–4, with 4 having the worst prognosis. Cellular morphology, mitotic activity, and tumor invasiveness, are all used to assign grade.

**REFERENCES**

**MC-CUNE–ALBRIGHT SYNDROME**

**DESCRIPTION**

A syndrome characterized by a classic triad of fibrous dysplasia (cystic bone lesions), gonadotropin-independent precocious puberty, and cutaneous pigmentation with cafe-au-lait spots. It is caused by a mutation of chromosome 20q13, coding for the α-subunit of G-protein coupled receptors that are involved with many hormone receptor signaling pathways.

**SYNONYMS**

- Polysystic fibrous dysplasia
- Distal fibrous cystoscopy

**TREATMENT**

Treatment is targeted at the specific endocrinopathy and may include:

- Hypothalamic surgery
- Adrenalectomy
- Aromatase inhibitors, anti-estrogens, and anti-androgens

**REFERENCES**

**ME-GUIRE URINAL**

**DESCRIPTION**

An external male urine collection device consisting of a malleable latex urinary catheter that is either self-contained or attached directly to a leg bag. It is often supported by fabric suspensions in a joey-strap type fashion.

**REFERENCE**

**MEATL STENOSIS, URETHRAL, MALE**

**DESCRIPTION**

Most commonly seen after neonatal circumcision, this acquired condition is theorized to follow a postsurgical inflammatory reaction at the glans, resulting in an extremely narrow urethra. Meatal stenosis is usually not apparent until the child is toilet trained. Strength and direction of stream can be affected. Dysuria, frequency, incontinence, and hematuria are symptoms that have been associated with this condition. Meatal stenosis rarely causes obstructive changes in the urinary tract. Meataloplasty is the corrective procedure for these requiring surgical correction. (See also Section II: “Catheter, Mucus and Urethra.”)

**REFERENCES**

**MECKEL–GRUBER SYNDROME (MECKEL SYNDROME)**

**DESCRIPTION**

Meckel–Gruber syndrome is a rare, lethal, autosomal recessive disorder with major characteristic features consisting of the triad of occipital encephalocele, polydactyly, and bilateral polycystic kidneys. Prenatal sonographic exam has been demonstrated to be of valuable diagnostic accuracy. For this reason, appropriate prenatal counseling is advocated for those at high risk.

**REFERENCE**

**MEDIAN BAR**

**DESCRIPTION**

Median bar refers to prostatic posterior commissural hyperplasia, an abnormal hyperplasia involving the posterior bladder base that produces a wide bar. Patients suffering enlargement of the middle lobe or posterior commissure are more likely to develop obstructive symptoms due to the tissue location, which easily obstructs the bladder neck. This explains the correlation between the size of the gland and the degree of obstruction.

### MEDULLARY CYSTIC KIDNEY

**DESCRIPTION**

A nonobstructive enlargement of the calyces due to a congenital malformation of the renal papilla. There is no dilatation of the renal pelvis, and no evidence of UPJ obstruction. Found almost exclusively in males (6:1), it often presents in children due to a UTI workup or in adults with menuriasis and renal calculus. The clinician must differentiate between hypersphincterism and UPJ obstruction.

**TREATMENT**

Not necessary. A diuretic renogram should fail to demonstrate any obstruction.

**REFERENCE**

### MEGACYSTIS, CONGENITAL

**DESCRIPTION**

A distal, thin-walled bladder with a wide and poorly developed trigone. Because of the widenly displaced ureters, vesicoureteral reflux is commonly seen. Bladder contractility is normal, but most urine refluxes retrograde into the collecting system. Connection of the reflux often results normal bladder dynamics. It is most often diagnosed on prenatal US. It is associated with megacysto- microcystic-renal polycystic syndrome, a rare congenital disorder characterized by a dilated, nonobstructive urinary bladder and hyperostosis of the skull.

**TREATMENT**

Correction of vesicoureteral reflux after 6 mo of age.

**REFERENCE**

Megalourethra is an extremely rare congenital deficiency of the mesodermal tissues of the phallicus. It can be best described as a urothelial diverticulum that affects the entire penile urethra. 2 types have been described, scaphoid and fusiform. Scaphoid megalourethra are more common and have an absence of corpus spongiosum whereas fusiform megalourethra lack both spongiosum and corpus cavernosum. Often associated with lethal congenital anomalies, fusiform megalourethra are present in some stillborns. Transient obstruction during early development may be responsible for the fusiform type. With the scaphoid type, a failure of development of erectile tissue is present, a meandroidal defect similar to the pathophysiologic of prune belly syndrome (MPS). Many other conditions are associated, such as MPS, renal agenesis, hypopigmentation, cryptorchidism, and others. For MPS, urothroms may be needed secondary to bladder outlet dysfunction and renal failure. In surgical repair of the scaphoid type, longitudinal reduction urethroplasty over a catheter to decrease urethral caliber or plication techniques can be used. For the fusiform variant, each case is managed based on the amount of tissue present and the severity of disease (Image q).

MEGALOURETHRA

DESCRIPTION Megalourethra is an extremely rare congenital deficiency of the mesodermal tissues of the phallicus. It can be best described as a urothelial diverticulum that affects the entire penile urethra. 2 types have been described, scaphoid and fusiform. Scaphoid megalourethra are more common and have an absence of corpus spongiosum whereas fusiform megalourethra lack both spongiosum and corpus cavernosum. Often associated with lethal congenital anomalies, fusiform megalourethra are present in some stillborns. Transient obstruction during early development may be responsible for the fusiform type. For the fusiform variant, each case is managed based on the amount of tissue present and the severity of disease (Image q).

MELANOMA, ABDOMINAL/PELVIC

MELANOMA, GENITOURINARY

DESCRIPTION Malignant melanoma of the GU tract is rarely seen. However, lesions of the penis, scrotum, and urothra can present as primary sites of disease. Secondary melanoma metastatic to the GU tract is a common autopsy finding. The majority of patients whose secondary melanoma is discovered clinically have metastatic disease within 2 yr.

MELANOMA, URETHRAL

DESCRIPTION A malignant degeneration of melanocytes and nerve cells, primary malignant melanomas are rare. The urethra is the preferred site of the urinary tract and accounts for ~4% of urothelial cancers. A urethral melanoma is more likely to be primary compared with cases in the bladder or kidney. It is 3 times more common in women, more frequent in the white population, and most commonly affects the distal urethra. Presentation is similar to that of other urothelial tumors, but melanoma is sometimes seen. It may be confused with urethral polyps, caruncles, mucosal prolapse, or more common urothelial tumors. It is most malignant melanoma of the adventitial plane. A rarer variant, deep dermal melanoma, crops up in the bladder of young, black women. In the local setting, it is the most common primary melanoma of the urinary tract. Carcinoma, General Considerations.”

TREATMENT

- Limited data are available; most are treated with radical surgery and frequently bilateral lymph node dissection.
- Chemotherapy, immunotherapy, and radiotherapy may be used at the discretion of the principal investigator; both are experimental.

MENOPAUSE, UROLOGIC CONSIDERATIONS

DESCRIPTION Menopause is the cessation of the menstrual cycle and is caused by reduced secretion of the ovarian hormones estrogen and progesterone. This causes a variety of symptoms, including those that affect the GU tract. Vaginal side effects such as dryness (40%), itching, and vaginal dryness (50–55%) occur secondary to reduced estrogens and androgenic hormones. A change in the pH of vaginal fluid from acidic to neutral that increases urinary infections. Decreased estrogen contributes to collagen loss and subsequent pelvic organ prolapse and urinary symptoms. Urinary incontinence and irritative bladder symptoms occur in 20–40% of perimenopausal and postmenopausal women.

TREATMENT

- Topical estrogen therapy has been shown to decrease the incidence of urinary infections, increase bladder control with reduction in urge and irritative symptoms, and improve vaginal dryness and atrophy. It has no effect on stress urinary incontinence (SUI).
- The use of hormone therapy is generally on a short-term basis and only for symptomatic individuals. Although it has been shown to possibly have cardioprotective effects, an increase in breast cancer risk is also seen.

MENKES SYNDROME (MENKES KINKY HAIR DISEASE)

DESCRIPTION A rare congenital disorder of copper metabolism with an X-linked recessive inheritance. Symptoms appear in the neonatal period and include hypothermia, poor feeding, and impaired weight gain. Neuropathic function progressively deteriorates. A colorless and friable hair is characteristically found. There tends to be a high incidence of GU conditions, including bladder diverticula, UTI, IP: obstruction, vesicoureteral reflux, and cryptorchidism.

Patients with urolithiasis should undergo metabolic stone evaluation to identify risk factors for future stone formation. This evaluation may diagnose uncommon, but potentially serious, stone-forming diseases:

- Metabolic syndrome
- Urolithiasis
- Hyperparathyroidism
- Hypercalcemia
- Diabetic nephropathy
- Hypertension
- Hypothyroidism
- Cystinuria
- Idiopathic hypercalciuria
- Hyperuricemia

This evaluation includes:

- A 24-hour urine collection
- A fasting blood sample
- A physical examination

The results help guide treatment and prevent future stone formation.

**REFERENCE**

**SYNONYMS**
- Hypercalciuria
- Hyperuricemia
- Cystinuria
- Idiopathic hypercalciuria
- Hyperuricosuria

**TREATMENT**
- Lifestyle modifications to reduce stone formation
- Medications to prevent stone recurrence
- Surgery for large stones

**MESOTHELIOMA, MALIGNANT, TESTICULAR TUNIC**

**DESCRIPTION**
Mesothelioma is a rare tumor arising from the mesothelial lining of the parietal or visceral peritoneum. It affects men more frequently than women and is more common in smokers. The peritoneum is the serous membrane that lines the abdominal cavity and covers the abdominal organs. Peritoneal surface mesothelioma is the most common type.

**TREATMENT**
Surgical resection is considered for localized tumors, whereas chemotherapy and radiation are used for disseminated disease. Adjuvant therapy is occasionally recommended.

**REFERENCE**

**METABOLIC STONE EVALUATION (24-HR URINE STUDIES)**

**DESCRIPTION**
Patients with urolithiasis should be encouraged to retrieve stones or stones removed surgically should be submitted for stone analysis. The evaluation’s extent depends on the patient’s history and physical examination.

**REFERENCE**

**Cystine screening** is performed on an optional basis and is not part of standard metabolic stone evaluation unless following patients with cystinuria.

**REFERENCE**

**METABOLIC SYNDROME, UROLOGIC CONSIDERATIONS**

**DESCRIPTION**
An increasingly more prevalent disease affecting ~22% of American adults, metabolic syndrome is characterized by having any of the following: abdominal waist circumference, hypertension, low HDL, hypertriglyceridemia, low HDL, hypertension, or abdominal fasting glucose parameters. Sexual dysfunction can occur, including hypogonadism and erectile dysfunction (ED). Many patients have a low urinary pH, thus increasing the risk of uric acid stones.

**SYNONYMS**
- Syndrome X
- Insulin resistance syndrome
- Obesity dyslipidemia syndrome

**TREATMENT**
- Lifestyle modifications with dietary changes, increased physical activity, and smoking cessation
metanephric adenoma (Image from RCC on imaging studies. WT1 and CD57 metastases were reported. It cannot be differentiated from a benign neoplasm but in 1 case lymph node metastases were reported in 12% of the cases that resolves after nephrectomy, but all have been treated with Wilms tumor chemotherapy. There has been 1 case described with nodal metastases of the papillary RCC component of their tumor.

REFERENCE

METANEPHRIC ADENOFIBROMA, KIDNEY (NEPHROGENIC ADENOFIBROMA)

DESCRIPTION A peduncular renal tumor with stromal features resembling congenital mesoblastic nephroma. The epithelial component has varying levels of activity ranging from inactive metanephric adenoma to Wilms tumor. Some masses contain areas identical to papillary RCC. Lesions with a Wilms tumor component occur at a young age (mean of 12 mo). No tumors have recurred after nephrectomy, but all have been treated with Wilms tumor chemotherapy. There has been 1 case described with nodal metastases of the papillary RCC component of their tumor.

REFERENCE

METANEPHRIC ADENOMA

DESCRIPTION A recently recognized renal tumor originally described in 1980; it shows a cytologic resemblance to early metanephric tubular differentiation and to the metanephric hamartomatous element of nephroblastomatosis. Fewer than 100 cases have been reported, with a 2:1 female to male predominance. Most cases present in the 1st-4th decades of life, and the lesion is often discovered incidentally. An association with polycythemia has been reported in 12% of the cases that resolves after surgical resection. These adenomas appear unremarkable, rarely multifocal. The majority are either unencapsulated or have only a limited and discontinuous pseudocapsule. It is largely regarded as a benign neoplasm but in 1 case lymph node metastases were reported. It cannot be differentiated from RCC on imaging studies. WT1 and CD99 immunohistochesizing stains in the diagnosis of metanephric adenoma (Image 9).

REFERENCE

METAPYRONE TEST

DESCRIPTION Cushing syndrome describes the symptom complex caused by excess circulating glucocorticoids. Metapyrone is a blocking agent used to reduce the secretion of cortisol peripherally, thereby lessenig the severity of symptoms. Metapyrone blocks the conversion of 11-deoxycortisol to cortisol. It is a diagnostical test for hypothalamic–pituitary ACTH function.

Day 1: Control period: Collect 24-hr urine to measure 17-hydroxy cortisol or 17-ketosteroids.
Day 2: ACTH test: 50 units ACTH infused over 8 hr and measure 24-hr urinary steroids. Days 3–4: Rest period.
Day 5: Administer metapyrone with milk or snacks. (Adult: 750 mg PO q6h for 6 doses; Pediatric: 15 mg/kg q6h for 6 doses [min 250 mg dose]).
Day 6: Determine 24-hr urinary steroids.
Normal 24-hr urine 17-OHCS is 3–12 mg; following ACTH, it increases to 15–45 mg/24-hr; normal response to metapyrone is a 2–4-fold increase in 17-OHCS excretory drug interactions with phenytin, cyclophosphamide, and steroids may lead to subnormal response.

REFERENCE

MEYER–WEGGART LAW

DESCRIPTION In cases in which separate ureteric buds on the same mesonephric duct form a completely duplicated collecting system, separate investigators (Higgin and then Meyers) noted that there exists a consistent relationship between the upper and lower pole orifices as they relate to 1 another on the trigone. The caudal, or distally placed, orifice actually drains the upper pole moiety, whereas the cranial, or suprasciopic orifice drains the lower pole moiety. The distal orifice is more medial on the trigone, as opposed to the laterally placed cranial orifice. This is a reliable rule for cases of ureteral duplication.

REFERENCE

MIBG SCAN

DESCRIPTION A form of molecular imaging using metaiodobenzylguanidine (MIBG), an analog of guanethidine. MIBG accumulates into cells via norepinephrine transporters and is collected into secretory granules. It is useful in identifying primary and metastatic pheochromocytoma, paraganglioma, and neuroblastoma.

REFERENCE

MICHAELIS–GUTMANN BODIES

DESCRIPTION Michaelis–Gutmann bodies are the pathognomonic finding in the benign inflammatory process known as malakoplakia. Low light microscopy demonstrates a granulomatous inflammatory process, characterized by the accumulation of large mononuclear cells with abundant granular cytoplasm and PAS-positive calcium immunoprecipitate inclusions (so-called Michaelis–Gutmann bodies). On electron microscopy, such inclusions appear as concentric lamellated structures with a mineralized core (Image 3).

REFERENCE

MICROCYSTIC/NESTED VARIANT UROTHELIAL CARCINOMA

DESCRIPTION Microcystic and nested variant urothelial carcinomas are rare histologic subtypes of bladder cancer that appear similar to benign conditions of the bladder, however demonstrate aggressive behavior. Microcystic urothelial carcinoma has an ill-defined growth pattern that resembles cystitis cystica. It has been identified in bladder, upper tract, and prostate urothelial carcinoma. Microcystic variant urothelial carcinoma is usually mistaken for reactive or athermatic. Studies have shown that in patients with microcystic variant urothelial carcinoma has a better prognosis than conventional urothelial carcinoma.

REFERENCE

MICRORHISLATHIA, TESTIS

DESCRIPTION Testicular microthelia is an uncommon condition characterized by the presence of collections within degenerating seminiferous tubules. It is a soft indurated tubule that shows providers of between 2 and 8% of males. Microthelia is often found in conjunction with other testicular pathologies, with testicular malignancy being the most concerning, however, there are conflicting reports. Currently, no guidelines exist for follow-up of patients diagnosed with microthelia of the testis. Recommendations range from no follow-up to a staging workup for testicular cancer. At a minimum, testicular self-exams are important and annual physical exam by a physician is recommended. Some authors suggest annual exam by a urologist in conjunction with annual ultrasound for patients with risk factors for testicular cancer (Image 8).

REFERENCE

MICROPAPILLARY BLADDER CANCER

DESCRIPTION A variant of bladder cancer first described in 1984. The histologic features closely resemble papillary versus carcinoma of the neck. It accounts for 0.7–2.3% of all bladder tumors and is nearly always associated with an advanced stage of...
MICTURITION SYNOCOPE

DESCRIPTION: Syncope episodes occurring during voiding are known as micturition syncope. This was originally thought to be a disorder of young healthy men, however, additional studies have found micturition syncope in spous ages and genders. Several mechanisms have been suggested in the literature. 1 is that decompression of the bladder results in a decreased intra-abdominal pressure therefore decreasing blood return and causing a sudden decrease in cerebral blood flow. Another is that increased vagal tone during voiding results in a syncopal episode. Finally, micturition syncope could be an orthostatic event as a result of waking from sleep that occurs during the 1st void of the day immediately after awakening. Rarely, micturition syncope can be a symptom of a pheochromocytoma/pheanglioma of the bladder. Further investigation with urinalysis and cystoscopy are warranted in addition to workup of a cardiovascular source of syncope.

MILK ALKALI SYNDROME

DESCRIPTION: Hypercalcemia and alkalosis associated with the ingestion of large amounts of milk and antacids containing calcium and absorbable alkali. Patients can develop nephrocalcinosis and renal insufficiency, but typically do not have hypercalcemia. The associated vomiting and dehydration can produce further volume contraction and alkalosis. (See also Section I: “Nephrocalcinosis, Adult.”)

TREATMENT: Withdrawal of milk and alkali, with gentle hydration to lower serum calcium. Vomitus can result in rebound hypercalcemia due to the chronic suppression of the parathyroid glands.

Mixed Epithelial Stromal Tumor of the Kidney (MEST)

DESCRIPTION: MEST is a subset of benign renal tumors composed mainly of smooth muscle cells in which epithelial structures are embedded. It is usually found in middle-aged and perimenopausal women. Grossly, MEST is well-circumscribed but unencapsulated, and cystic or a cut surface. Microscopically, it is composed both of epithelial structures similar to renal tubules and stroma comprising non-specific spindle cells. The differential diagnosis for these tumors is focus cystic nephroma and cystically differentiated nephroblastoma.

Milk-Alkali Syndrome

MILK–ALKALI SYNDROME

DESCRIPTION: Hypercalcemia and alkalosis associated with the ingestion of large amounts of milk and antacids containing calcium and absorbable alkali. Patients can develop nephrocalcinosis and renal insufficiency, but typically do not have hypercalcemia. The associated vomiting and dehydration can produce further volume contraction and alkalosis. (See also Section I: “Nephrocalcinosis, Adult.”)

TREATMENT: Withdrawal of milk and alkali, with gentle hydration to lower serum calcium. Vomitus can result in rebound hypercalcemia due to the chronic suppression of the parathyroid glands.

MINTROFANOFF PRINCIPLE

DESCRIPTION: A surgical procedure, originally described by Mitrofanoff, in which the appendix is excised with a button of cecum, reversed, and tunneled to create a catheterizable channel with a reported continence rate of 93–100%. Stomal stenosis is an early complication affecting 7–24% within 3 yr in published series.

MIXED EPITHELIAL STROMAL TUMOR OF THE KIDNEY (MEST)

DESCRIPTION: MEST is a subset of benign renal tumors composed mainly of smooth muscle cells in which epithelial structures are embedded. It is usually found in middle-aged and perimenopausal women. Grossly, MEST is well-circumscribed but unencapsulated, and cystic or a cut surface. Microscopically, it is composed both of epithelial structures similar to renal tubules and stroma comprising non-specific spindle cells. The differential diagnosis for these tumors is focus cystic nephroma and cystically differentiated nephroblastoma.

MOLLUSCUM CONTAGIOSUM

DESCRIPTION: A benign, self-limited skin tumor or papular eruption caused by a virus. Infection occurs after breakage of the skin and characteristically begins as a small pimple. When mature, it is a discrete 2–5 mm smooth, dome-shaped, pearly or flesh-colored nodule that is often umbilicated. Single to hundreds of lesions may track alone the line of a scratch. In adults, they occur on the trunk, thigh, and public areas. Lesions usually disappear by themselves within 6–12 mo, although this may take up to 4 yr with impaired cell mediated immunity. Diagnosis is usually clinical, but brick-shaped vesicles can sometimes be seen under negative-stain electron microscopy. Henderson-Paterson bodies are characteristic. Often seen on pathology. (See also Section I: “Genital Warts.”)

TREATMENT: Observation is reasonable for nongenital lesions. Caustic is useful for treating a few lesions; scraping may develop.

MONDOIR DISEASE

DESCRIPTION: Mondor disease is superficial thrombophlebitis of the dorsal vein of the penis. It is typically diagnosed in young males after excessive sexual activity and can be diagnosed in older males due to venous obstruction secondary to bladder disinterest. Physical exam typically reveals a tender palpable cord on the dorsal surface of the penis as well as distal penile edema. Treatment is conservative with abstinence of sexual activity until completely resolved. Anticoagulation and antiphlogistics medications have not been shown to be beneficial. Vein stripping surgery is indicated for patients with associated cellulitis.

MONOFORT TECHNIQUE

DESCRIPTION: A type of abdominal wall reconstruction in patients with prune belly syndrome. This technique utilizes an abdominal incision that preserves the umbilicus and thickens and strengthens the anterior abdominal wall. Full-thickness resection of the parietal peritoneum is performed, and the anterior wall is sutured in a double-breasted fashion preserving vascularity and the umbilicus. This technique offers excellent exposure for concomitant intra-abdominal surgery.

MONTI PROCEDURE

DESCRIPTION: Also known as the Monti procedure, this technique most often used in children to create a continent catheterizable stoma. A short segment of bowel (2–3 cm of ileum) is included...
along the antimesenteric border and then closed transversely to create a uniform tube that can be tunneled into the bladder and out through the abdominal wall. This allows preservation of the appendix for the Malone antegrade continent enema (MACE) procedure. A review of 199 patients undergoing Monti ileovesicostomy at a single institution reported a revision rate of 8.5% and a continence rate of 96.5% with mean follow-up of 28 mo.

**MOHRIS SYNDROME**

**DESCRIPTION**

An intense disorder that affects 1 in 20,000 live male births; it is caused by a mutation in the androgen receptor gene located on the long arm of the X chromosome. This prevents appropriate androgen binding and/or function. If complete androgen insensitivity occurs, the child will appear to have a normal female phenotype and the testes are located internally. Many children are diagnosed at the time of hernia repair as infants or not diagnosed until puberty during an evaluation for primary amenorrhea. **SYNONYMS**

- **Testicular feminization syndrome**
- **In-class of male pseudohermaphroditism**

- **REFERENCE**

**MOSTOFI (WHO) GRADING SYSTEM**

**DESCRIPTION**

- **Grade I:** Well-differentiated, with slight nuclear anaplasia
- **Grade II:** Moderately differentiated, with moderate nuclear anaplasia
- **Grade III:** Poorly differentiated, with marked nuclear anaplasia, and/or differentiated carcinoma

- **SYNONYM**

  World Health Organization Grading System

- **REFERENCE**

**MOWAT-WILSON SYNDROME**

**DESCRIPTION**

A syndrome of multiple congenital anomalies due to a heterozygous mutations or deletions in ZEB2, or Zinc finger E-box-binding homeobox 2 gene. It is generally discussed on genetic workup for Hirschsprung disease. Patients present with a distinct facial phenotype, mental retardation, lipoatrophy, agenesis of corpus callosum, and congenital heart defects. Roughly 50% of patients have genitourinary anomalies with hypoplasia being the most prominent (52%). Another common anomaly is cryptorchidism (39%). Rhinitis, scrotophelial reflux and misunderstood are rare but have been reported.

- **REFERENCE**

**MUCORMYOSIS, GENITOURINARY**

**DESCRIPTION**

A fungal infection that usually affects immunocompromised patients. Patients receiving hemodialysis and diabetics are at particular risk for disseminated disease. The kidneys are the organs most often involved in the GU system, but penile involvement has also been reported. The course is usually fatal. (See also Section I: “Fungal infections, Genitourinary.”)

- **TREATMENT**

  Amphotericin B systemically; nephrectomy for involved kidney

- **REFERENCE**

**MULBERRY STONES**

**DESCRIPTION**

A term that refers to the surface appearance of irregular calcium oxalate dihydrate stones often seen in the bladder. Based on their less well-developed spikes than seen on pectinate; the spikes possess more of a mammillated appearance.

- **REFERENCE**

**MULCAHY PROTOCOL**

**DESCRIPTION**

Infection of a penile prosthesis is suspected when there is local pain and erythema, fever and listlessness of the prostheses components. In this situation there are 2 main options. The 1st is to remove the prosthesis and reinser it at least 6–8 mo later. This repeat surgery can be difficult due to formation of scar tissue in the corpora. Another option is to remove the prosthesis, perform a corporos antibiotic washout of the corpora cavernosa with an antibiotic solution, then place a “tutor” cylinder inside the corpora to prevent shrinking and scarring.

Another approach to the management of an infected penile prosthesis is the Mulcahy protocol. This involves complete removal of the infected part of the prosthesis and all other components followed by the use of the specific Mulcahy salvage procedure outlined below with reinser tion of a new penile prosthesis in the same sitting with a reported success rate of 85%. (See also Section I: “Penile Prosthesis Problems.”)

**MULTIPLICATION**

**REFERENCE**

- Administer oral antibiotics for 1 month
- Change gowns, gloves, surgical drapes, and all other components followed by the use of the specific Mulcahy salvage procedure outlined below with reinser tion of a new penile prosthesis in the same sitting with a reported success rate of 85%. (See also Section I: “Penile Prosthesis Problems.”)
- Remove all prosthetic parts and foreign material
- Irrigate wounds using 5 antiseptic solutions: – Antibiotic solution (1 g vancomycin and 80 mg gentamicin in 1 L of normal saline) – 1/2 strength Povidone-iodine (Betadine or similar) – Pressure washing with 1 g vancomycin and 80 mg gentamicin in 5 L irrigation – 1/2 strength Povidone-iodine (Betadine or similar) – Antibiotic solution rinse
- Change gowns, gloves, surgical drapes, and instruments immediately before prosthesis insertion
- Insert new prosthesis
- Close wounds with no drains or catheters
- Administer oral antibiotics for 1 month

**REFERENCES**

- Mulcahy KD, Oukhors AO. Mucin-producing tumors of the sebaceous gland or keratoacanthoma associated with ≥1 visceral malignancies including renal, endometrial, prostatic, and upper GI. MÜLLERIAN DUCT REMNANTS AND SYNDROME (PMDS)

DESCRIPTION: Refers to the persistence of the müllerian duct structures (ovary, fallopian tubes) in the genotypically and phenotypically normal male. The remnants period due to the absence of müllerian inhibiting substance. It is an autosomal recessive inherited disorder. Patients present with cryptorchidism and hernia, and the persistent müllerian structure are found within the hernia sac. Increasing evidence is mounting that persistent müllerian structures are at risk for malignant transformation. 11 cases of malignancy have been reported in the literature out of 200 reported cases of persistent müllerian duct syndrome (PMDS).

SYNONYMS: • Prostatic stricture cyst • Müllerian duct cyst (Image 4)

MULTILOCULAR CYSTIC NEPHROMA (CYSTIC NEPHROMA, MULTILOCULAR CYST)

DESCRIPTION: Around, well-encapsulated multilocular cystic mass whose septae are composed of well-differentiated tissues, without blastic elements. The current thinking is that multilocular cystic nephroma is at the benign end of a spectrum that includes cystic partially differentiated nephroblastoma (CPDN) and cystic nephroma at the malignant end. Usually, multilocular cystic nephroma and CPDN look identical. The contents of the cysts consist of either yellow fluid or thick myxomatous gel. The lesion is usually solitary but rarely can be multiple. Cystic nephroma presents in a bimodal age distribution of 2–6 years (male-50% female-50%) and in adulthood (81% female-9%). Children usually present with a palpable mass and adults with pain; hematuria, or infection. Imaging cannot distinguish between cystic nephroma and CPDN. The lesion often is close to the renal pelvis, and herniation of the renal pelvis is a pathognomonic finding on US, CT, or MRI. The nephromas separate the cysts. On US, multiple anechoic spaces representing the cysts may be seen. The septa are thin, variable in thickness, and are not uniformly thick. The septa are not calcified and cannot be distinguished from thin vessels. Imaging cannot reliably separate CPDN from nephroma that extends beyond the normal renal outline. Children usually present with a palpable mass and adults with pain, hematuria, or infection. Imaging cannot distinguish between cystic nephroma and CPDN. On US, CT, or MRI, the lesions are usually solitary but rarely can be multiple. Cystic nephroma presents in a bimodal age distribution of 2–6 years (male-50% female-50%) and in adulthood (81% female-9%). Children usually present with a palpable mass and adults with pain; hematuria, or infection. Imaging cannot distinguish between cystic nephroma and CPDN. The lesion often is close to the renal pelvis, and herniation of the renal pelvis is a pathognomonic finding on US, CT, or MRI. The nephromas separate the cysts. On US, multiple anechoic spaces representing the cysts may be seen. The septa are thin, variable in thickness, and are not uniformly thick. The septa are not calcified and cannot be distinguished from thin vessels. Imaging cannot reliably separate CPDN from nephroma that extends beyond the normal renal outline.

MULTIPLE ENDOCRINE NEOPLASIA (MEN I, MEN II)

DESCRIPTION: A group of inherited syndromes primarily consisting of endocrine tumors of both benign and malignant nature. MEN syndrome lesions are of unilgic interest because of the possibility of adrenal involvement, hyperparathyroidism, renal stones, and hypercalcemia.

• MEN I (Werner’s syndrome): Autosomal dominant condition with neuroendocrine parathyroid, pancreas, duodenal, and pharyngeal lesions. Cutaneous tumors also may be seen (angiofibromas, others). Hyperparathyroidism is the most common presentation of this syndrome, but overall this is a rare cause of hyperparathyroidism in the general population. Primary lesions may cause hyperplasia and ACTH-producing lesions.

• MEN II (ipple syndrome): Autosomal dominant: Type IA: Pheochromocytoma, medullary carcinoma of the thyroid, parathyroid adenoma Type IB: Phaeochromocytoma, medullary carcinoma of the thyroid (but not parathyroid hyperplasia) with mucosal neuromas, intestinal ganglioneuromas, and occasionally marfanoid habitus. Some literature refers to this as MEN III (mucosal neuromuscular syndrome).

MULTIPLE MYELOMA, UROLOGIC CONSIDERATIONS

DESCRIPTION: A malignant proliferation of plasma cells derived from a single clone. The classic triad involves marrow plasmacytosis, light bone lesions, and a serum and/or urine M component. Renal failure occurs in 25% of patients. Hypercalcemia is the most common cause, but hyperuricemia is also present and a rarely cause. Tumor lysis syndrome is uncommon with multiple myeloma. There may be tubular precipitation of light chain proteins (myeloma kidney), urinary obstruction due to uric acid or calcium-containing stones, or recurrent pyelonephritis. Gliomblastoma, tubule, and interstitial involvement can cause renal insufficiency. The development of a myeloma kidney can lead to adult Fanconi syndrome, which is a type II proximal renal tubular acidosis. NSAIDs are to be avoided. Renal failure is rare but has been reported after the use of contrast agents in patients with multiple myeloma.

MUMPS ORCHITIS

DESCRIPTION: Mumps is a single-stranded RNA virus (paramyxovirus) viral. After the prodromal period, 1 or both parotid glands begin to enlarge. Mumps orchitis follows the development of parotitis by 4–7 days, with about 25% of males developing orchitis (10% bilateral and 80–90% unilateral). It has been reported following mumps vaccination. The presentation is high fever, testicular pain, and swelling. The management of mumps orchitis is supportive (bedrest, social support, analgesics) with resolution in about 7 days. Unilateral testicular atrophy occurs in 60%. Impaired fertility can affect up to 15%, but fertility is rare. (See also Section II: “Obstetrical General.”)

MURCS ASSOCIATION (MÜLLERIAN DUCT, RENAL, AND CERVICAL VERTEBRAL DEFECTS)

DESCRIPTION: MURCS association consists of a novel association of müllerian duct aplasia, renal aplasia/agenesis, and cervicothoracic somite dysplasia. The incidence of cervicothoracic-vertebral defects, especially from C5–T1, is 80%. Other abnormalities may include spinoglenoid defects, upper limb defects, and moderately frequent rib anomalies. It is the 2nd most frequent cause of primary amniarhoea after Turner syndrome.

MUSCLE FLAP TYPES, UROLOGIC CONSIDERATIONS

DESCRIPTION: Muscle flaps are a reconstructive technique using local or distant muscle donor sites to provide tissue coverage in complex reconstructive procedures. The most simple muscle flaps are local and regional flaps where blood supply of the muscle is not interrupted when the flap is repositioned to its new location. Pedicle and micro-skin free flaps are more complicated forms of tissue transfer that are finding new indications in reconstructive urologic procedures. Tissue transfer has become increasingly used in centers for complex repair of fistula disease following radiation. In addition, clinical study has shown latissimus dorsi transferred to acraliminate the rectus abdominies has restored voluntary voiding in patients with detrusor anuria.

MUSTARDÉ HYPOSPADIAS REPAIR

DESCRIPTION: A more extensive Mustarde technique in which the ventral flap is mobilized to form a neourethra and then transposed distally. The glans wings are often approximated over the neourethra.

MULTIPLE CYSTIC NEPHROMA (CYSTIC NEPHROMA, MULTILOCULAR CYST)

DESCRIPTION: Around, well-encapsulated multilocular cystic mass whose septae are composed of well-differentiated tissues, without blastic elements. The current thinking is that multilocular cystic nephroma is at the benign end of a spectrum that includes cystic partially differentiated nephroblastoma (CPDN) and cystic nephroma at the malignant end. Usually, multilocular cystic nephroma and CPDN look identical. The contents of the cysts consist of either yellow fluid or thick myxomatous gel. The lesion is usually solitary but rarely can be multiple. Cystic nephroma presents in a bimodal age distribution of 2–6 years (male-50% female-50%) and in adulthood (81% female-9%). Children usually present with a palpable mass and adults with pain; hematuria, or infection. Imaging cannot distinguish between cystic nephroma and CPDN. The lesion often is close to the renal pelvis, and herniation of the renal pelvis is a pathognomonic finding on US, CT, or MRI. The nephromas separate the cysts. On US, multiple anechoic spaces are seen, separated by hyperchoic septa. CT reveals a well-marginated, rounded, or polycystic cortical mass that extends beyond the normal renal outline. Enhancement of the septa may be seen due to the presence of thin vessels, imaging cannot reliably predict malignant potential.

SYNONYMS: • Cystic kidney, cystic nephroma • Local polycystic kidney • Multilocular or cystic adenoma

TREATMENT: • Partial nephrectomy or radical nephrectomy is indicated. • Follow-up is required because of local recurrence (Image a).

730
Mycoplasma hominis

**DESCRIPTION**

Mycoplasma hominis is a common organism that resides in the genital tracts of both men and women. However, it may be a cause of choriocytotropism in men or vaginal infections in women. Identifying and culturing this organism is difficult. Initial treatment includes doxycycline 100 mg BID for 2 wk or azithromycin 1 g in a single dose.

REFERENCES

Mycoplasmal pain, urogenital conditions

**DESCRIPTION**

Gracilis flap: The origin of the gracilis muscle is the medial tibia. The gracilis muscle is a branch of the obturator nerve, which provides full anterior thigh sensation. The gracilis muscle is a branch of the lateral femoral circumflex artery, and its blood supply is a single artery from the profunda femoris system.

Tension fascia lata flap: The tension fascia lata flap can be harvested from the lateral aspect of the upper leg. The vascular pedicle is comprised of the descending lateral circumflex femoral artery, and the sensory supply is the lateral femoral cutaneous nerve of the thigh, which originates from T12.

REFERENCES

Myocutaneous flaps

**DESCRIPTION**

Myocutaneous flaps, such as the rectus abdominis flap and the gracilis muscle flap, can be utilized during urogenital reconstructive surgery. Common applications for skin coverage during inguinal node dissections for penile cancer, closure of urinary fistula, and reconstruction afterourean surgery.

NAGAMATSU INCISION

**DESCRIPTION**

A dorsolateral incision is made over either the 11th or 12th rib, which is resected. After rib removal, the diaphragm and pleura are opened over either the 11th or 12th rib, which is resected. The diaphragm and pleura are opened over either the 11th or 12th rib, which is resected.

REFERENCES

Myoglobinuria

**DESCRIPTION**

Myoglobinuria is described by Fleischer in 1881. Myoglobinuria refers to the presence of excessive amounts of myoglobin, a protein found in muscle, in the urine. Myoglobinuria occurs when serum levels exceed the renal threshold. Myoglobin is released into the serum following massive muscle necrosis (rhabdomyolysis) from crush, compartment syndrome, electrical injury, burns, malignant hyperthermia, and other causes, and imparts a cola-like color to the urine. Diagnosis is made by electrophoresis separation and radioimmunooassay of urinary myoglobin. Serum creatinine kinase is elevated, and there is an absence of red cells in the urine. (See also Section I: “Rhabdomyolysis”; Section II: “Myoglobin Nephrotoxicity.”)

CAUSES

- Diabetic acidosis
- Fluid/electrolyte imbalance
- Infections myocutaneous
- Ischemia
- Malignant hyperthermia
- Neuromuscular malignant syndrome
- Rhabdomyolysis or compartment syndrome
- Trauma
- Trauma

TREATMENT

- Remove the causative agent.
- Protect against renal failure through correction of electrolyte imbalance, alkalization of urine with sodium bicarbonate, hydration, and diuretics.

Nephrocalcinosis, Neonatal

Nephrocalcinosis with or without nephrocalcinosis are commonly observed in both term and premature infants who have had difficult neonatal courses. Neonates with prolonged illness are at particular risk, especially those who still require oxygen at 28 days. While multifactoral, such as high calcium and phosphorous intake, loop diuretics appear to be the major cause in this group of patients. Loop diuretic use (furosemide most commonly used) predisposes to nephrocalcinosis by increasing urinary calcium excretion. Other factors such as immaturity renal function and physiologic hypercalciuria that occurs between 32 and 42 weeks of gestation contribute. Nephrocalcinosis in infants with a birth weight <1,500 g may be as high as 64% and may be independent of diuretic use. In infants born <32 wk gestation, 27% had nephrocalcinosis with 70% having been treated with a loop diuretic. Other causes of neonatal nephrocalcinosis include William syndrome (supravalvular aortic stenosis and hypercalcemia), neonatal primary hyperparathyroidism and distal type (1) renal tubular acidosis. The loop diuretic-induced hypercalciuria can be diminished and radiologic appearance of renal calcifications diminished by administering a thiazide diuretic in place of or alternating with a loop diuretic. The long-term impact of nephrocalcinosis on renal outcome is unclear because data are limited and inconsistent. Long-term follow-up is recommended.

REFERENCE

Nephrogenic adenoma (NA) and metaplasia

Description: A rare lesion occurring in the urinary tract that was once thought to be a metastatic reaction to chronic irritation and has now been shown to originate from unstimulated and implanted renal epithelial cells. It is named for its histologic similarity to renal tubules and can cause hematuria, dysuria, and urgency. On cytology nephrogenic adenoma can appear papillary, nodular, or sessile and is very friable. It is typically unifocal. It is considered a benign lesion, however malignant transformation has been reported and therefore complex resection and long-term follow-up is recommended.

REFERENCE

Nephrogenic adenoma (NA) and metaplasia

Description: A rare lesion occurring in the urinary tract that was once thought to be a metastatic reaction to chronic irritation and has now been shown to originate from unstimulated and implanted renal epithelial cells. It is named for its histologic similarity to renal tubules and can cause hematuria, dysuria, and urgency. On cytology nephrogenic adenoma can appear papillary, nodular, or sessile and is very friable. It is typically unifocal. It is considered a benign lesion, however malignant transformation has been reported and therefore complex resection and long-term follow-up is recommended.

REFERENCE

Prophylactic percutaneous radiotherapy (shown to reduce the incidence of Nelson syndrome by 50%)

REFERENCE

Nephrocalcinosis, with or without nephrocalcinosis are commonly observed in both term and premature infants who have had difficult neonatal courses. Neonates with prolonged illness are at particular risk, especially those who still require oxygen at 28 days. While multifactoral, such as high calcium and phosphorous intake, loop diuretics appear to be the major cause in this group of patients. Loop diuretic use (furosemide most commonly used) predisposes to nephrocalcinosis by increasing urinary calcium excretion. Other factors such as immaturity renal function and physiologic hypercalciuria that occurs between 32 and 42 weeks of gestation contribute. Nephrocalcinosis in infants with a birth weight <1,500 g may be as high as 64% and may be independent of diuretic use. In infants born <32 wk gestation, 27% had nephrocalcinosis with 70% having been treated with a loop diuretic. Other causes of neonatal nephrocalcinosis include William syndrome (supravalvular aortic stenosis and hypercalcemia), neonatal primary hyperparathyroidism and distal type (1) renal tubular acidosis. The loop diuretic-induced hypercalciuria can be diminished and radiologic appearance of renal calcifications diminished by administering a thiazide diuretic in place of or alternating with a loop diuretic. The long-term impact of nephrocalcinosis on renal outcome is unclear because data are limited and inconsistent. Long-term follow-up is recommended.

REFERENCE

NEPHROPATHY, URATE (URATE NEPHROPATHY)

DESCRIPTION
A disorder in which an abrupt tubular deposition of urate and uric acid crystals. Their chronic use leads to recurrent papillary necrosis with impaired concentrating ability, sterile pyuria, and renal insufficiency. Removal of phenacetin from OTC pain medications has drastically reduced the incidence of this condition. During periods of acute necrosis, patients may have flank pain, pyuria, hematuria, and acute ureteral obstruction from passage of sloughed, necrotic papillary tissue. H/P shows the ring sign, which refers to the contrast agent surrounding sloughed papilla, although the current use of H/P is limited due to contrast load. Renal US shows small kidneys, with irregular thinning of the renal cortex. Renal biopsy shows interstitial inflammation and fibrosis. Noncontrast CT shows bilateral reduced renal size, humpy renal cortex, and papillary calcifications (ie, small, indented, and calcified kidneys). The mechanism of injury is believed to be a combination of injury from the production of toxic metabolites and medullary ischemia. These patients are at increased risk of developing TCC of the urinary tract. Cessation of drug use can lead to stabilization of renal function.

REFERENCE

NEPHROPATHY, ISCHEMIC

DESCRIPTION
Ischemic nephropathy is described as a deterioration of renal function due to a reduction in renal blood flow, commonly caused by atherosclerotic renovascular disease or renal artery stenosis. The disease progresses with worsening renal failure and decreased overall survival. It can present as hypertension (HTN) with unexplained renal insufficiency, worsening azotemia with HTN, azotemia in the setting of coronary artery disease or peripheral vascular disease, ACE inhibitor-induced ARF, or flash pulmonary edema. Numerous tests are used to define the presence, site, and function of the kidneys, as well as to establish the presence of a vascular lesion and its clinical significance, including CT or MR angiography, conventional angiography, Doppler US, ACE I renography or renal vein renin measurements. Controversy still exists on the appropriate management of renal artery stenosis. Options include medical therapy, percutaneous transluminal angioplasty with or without stent placement, as well as surgical revascularization or nephrectomy. (See also Section I: “Renal Artery Stenosis/Renovascular Hypertension”.)

REFERENCE

NEPHROPATHY, MINIMAL CHANGE

DESCRIPTION
Minimal change nephropathy is the most common cause of idiopathic nephrotic syndrome, most often affecting children but can account for up to 15% of adult nephrotic syndrome. Sometimes called minimal change disease, this condition manifests as nephrotic syndrome, with massive proteinuria and anasarca without hyperension. NCS in the urine are a common finding; histologic evaluation shows essentially no changes on light microscopy. Electron microscopy shows epithelial foot process fusion. The pathogenesis is unknown, but T-cell dysfunction is theorized. The nephropathy can be primary or secondary to medications, neoplasms, infection, allergy, or other renal glomerular diseases; it frequently undergoes spontaneous remission, is responsive to corticosteroid therapy, and rarely progresses to chronic renal failure. (See also Section I: “Nephrotic Syndrome.”)

REFERENCE

NEPHROPATHY, OBSTRUCTIVE

DESCRIPTION
Obstructive nephropathy occurs when renal obstruction is due to obstruction of the urinary system. The point of obstruction can be in the upper or lower urinary tract. Congenital, inflammatory, neoplastic, and anatomic etiologies of urinary obstruction are all common. Obstruction of the outflow from the kidney results in several changes that lead to renal failure. The tubular injury in obstructive nephropathy is caused initially by the increased intratubular pressure and later by atrophy induced by reduced perfusion pressure, ischemia. The recovery of renal function after relief of the obstruction is determined by the duration of the obstruction, baseline renal function, patient age, and degree of obstruction. The total obstruction of the ureter, relatively complete recovery of GFR can be achieved within 1 wk, whereas after 12 wk, little or no recovery is seen. (See also Section I: “Hydronephrosis.”)

REFERENCE

NEPHROPATHY, URATE (URATE NEPHROPATHY)

DESCRIPTION
A disorder in which an abrupt deterioration in renal function occurs due to the renal tubular damage caused by uric acid crystals. Chronic renal injury from uric acid deposition is most often associated with gout and is uncommon today.

REFERENCE
Nephrotic Syndrome

2 forms are recognized, acute and chronic. Acute renal nephropathy occurs almost exclusively in the setting of malignancies, such as leukemia and lymphomas, with rapid cell turnover leading to increased purine metabolism and loss of nucleotides in the plasma. This is further enhanced by added acceleration of cell lysis, which occurs with chemotherapy and radiation used in these patients, producing the so-called tumor lysis syndrome. Nucleotides are converted to urate by xanthine oxidase, resulting in hyperuricemia with levels of 25–90 mg/dL at the time of onset of renal dysfunction. Diagnosis requires the appropriate clinical setting of increased cell lysis (usually with chemotherapy), oliguria, marked hyperuricemia, and hyperuricosuria. A urinary uric acid-to-creatinine ratio >1 distinguishes this from other catabolic states with hyperuricosuria. A urinary uric acid-to-creatinine ratio >1 distinguishes this from other catabolic states with increased serum urate levels and renal failure, such as trauma with rhabdomyolysis. (See also Section I: “Dietl Crisis.”)

TREATMENT
- Prevention is the key, using xanthine oxidase inhibitors with allopurinol and aldehyde dehydrogenase prior to initiation of chemotherapy.
- Alkalization of urine in the acute tumor lysis syndrome is not possible in the setting of renal diabetes.
- Rhabdovac (Esic) is recombinant urate oxidase that converts uric acid to water-soluble allantoin.
- Occasionally, dialysis is required to correct azotemia and reduce urate levels.

REFERENCE

NEPHROPTOSIS

DESCRIPTION
A largely historic classification system for describing the level of tumor thrombus associated with a renal mass. The categories are renal vein, vena cava, aorta, and confluence. The primary clinical application of nephropexy in renal cell carcinoma with tumor thrombus extension within the inferior vena cava, hepatic veins, and vena cava right atrial junction. The proportion of renal cell carcinoma patients with tumor thrombus in the inferior vena cava is approximately 5%.[2] This proportion is likely higher if patients demonstrating a more favorable prognosis for surgical resection are excluded. The role of nephropexy with respect to the management of renal cell carcinoma with tumor thrombus is to provide better surgical access, facilitate a potential cure, and improve patient survival. Nephropexy is performed when the tumor is too distant from the hilus for adequate surgical resection without additional morbidity. Nephropexy may be indicated in patients with high-risk tumors or when the tumor is too large to be removed safely. Nephropexy is performed by transperitoneal or retroperitoneal approaches. The transperitoneal approach is associated with a lower rate of complications, but the retroperitoneal approach allows for better visualization of the tumor and surrounding structures. The retroperitoneal approach is preferred for tumors involving the inferior vena cava, hepatic veins, and vena cava right atrial junction. The retroperitoneal approach is also associated with a lower rate of complications. Nephropexy should be performed by experienced surgeons with expertise in open and laparoscopic surgery.

REFERENCE

NEUROENDOCRINE TUMORS, GENITOURINARY

DESCRIPTION
A group of tumors that share a characteristic morphology, often being composed of clusters and trabecular sheets of round blue cells, granular chromatin, and an attenuated rim of poorly demarcated cytoplasm. Neuroendocrine tumors include carcinoids, small (blast) cell carcinomas, medullary carcinoma of the thyroid, Merkel cell tumor, cutaneous neuroendocrine carcinoma, pancreatic islet cell tumors, and pheochromocytoma. Small (blast) cell carcinomas have been described most often in the prostate and bladder. Prostate cancer with neuroendocrine differentiation is considered a variant of Gleason’s adenocarcinoma of the prostate. Undifferentiated carcinomas of the urinary bladder and prostate should be analyzed not only by means of hematoxylin and eosin but also by immunohistochemical staining for chromogranin A (Chr A) and synaptophysin (SNP), to demonstrate a neuroendocrine origin. Because the prognosis of small cell neuroendocrine cancers is very poor, aggressive multimodal therapy is often employed. (See also Section II: “Neuroendocrine Tumors,” Section III: “Multiple Endocrine Nodules (MEN I, MEN II),” “Prostate Cancer, Small Cell.”)

REFERENCE

NEUROFIBROMATOSIS, UROLOGIC CONSIDERATIONS

DESCRIPTION
A hereditary disorder characterized by cafe-au-lait spots, cutaneous fibromas, and neurofibromas. It is associated with renovascular lesions and pheochromocytomas. Vascular lesions are characterized by endothelial proliferation, with or without aneurysmal formation and cellular nodules in the vessel walls. The aorta is frequently involved, and the renal arteries may demonstrate large areas of stenosis that are generally best treated with revascularization rather than angioplasty. In addition, a 20-fold increase in the incidence of neurofibromatosis in patients with Wilms tumor has been reported.

REFERENCE

NEUROGENIC DETURS OVERACTIVITY (NDO)

DESCRIPTION
NDO patients are a heterogeneous group with both storage and voiding dysfunction. The NDD symptoms include urinary frequency, urgency, and incontinence. Neurogenic conditions associated with NDO include multiple sclerosis (MS), spinal cord injury (SCI) Parkinson disease, cerebral palsy, and myelomeningocele. Neurogenic bladder dysfunction is present in 80.8% of individuals with MS, 95% with myelodysplasia, virtually all SCI patients with persistent neurologic deficits and 70% of ambulatory SCI patients. NDO impacts quality of life and can also result in risk of UTI and upper urinary tract damage. Anticholinergic therapies such as oxybutynin are primarily used for patients with DO and poor compliance. CIC may be best for those who have poor bladder emptying. Although not FDA approved neuromodulation via sacral nerve stimulation is useful in patients who have failed anticholinergics. Intramuscular injection of onabotulinumtoxin A is FDA approved in the management of NDO in patients refractory or intolerant of anticholinergics. In selected individuals, a chronic indwelling catheter may be the best management therapy. Surgical intervention (bladder augmentation, urinary diversion, continent urinary diversion, and ileovesicostomy) may be indicated for protection of the upper urinary tract in high-risk patients or to achieve continence. (See also Section I: “Neurogenic Bladder, General Considerations.”)

REFERENCE

NEURONMODULATION, UROLOGIC CONSIDERATIONS

DESCRIPTION
Neuromodulation involves the use of electrical current to alter physiologic properties. This technology has been applied to lower urinary tract dysfunction for the past decade by stimulation of the sacral nerve roots. Sacral neuromodulation was approved in patients with overactive bladder refractory to medical and behavioral therapy by the FDA in 1997. A recent multi-institutional clinical trial shows success rates as high as 68% for urge incontinence, 56% for urgency-frequency, and 71% with obstructive urinary retention at 5 yr after implantation. Posterior tibial nerve stimulation is also being used. (See also Section II: “Posterior Tibial Nerve Stimulation: Urgent PC [PTN].”)

REFERENCE

NEVES–ZINCKE CLASSIFICATION

DESCRIPTION
A legacy of anatomic classification system for describing the level of tumor thrombus associated with a renal mass. The categories are renal vein, vena cava, aorta, and confluence. The primary clinical application of nephropexy in renal cell carcinoma with tumor thrombus extension within the inferior vena cava, hepatic veins, and vena cava right atrial junction. The proportion of renal cell carcinoma patients with tumor thrombus in the inferior vena cava is approximately 5%.[2] This proportion is likely higher if patients demonstrating a more favorable prognosis for surgical resection are excluded. Nephropexy should be performed by experienced surgeons with expertise in open and laparoscopic surgery.

REFERENCE
**NMP-22 TESTING**

Description: NMP-22 has been found to serve as a urinary marker for TCC. The NMP-22 test (Marinechip, Inv. Alpha, NA) is a quantitative immunassay that measures NMP-22. The addition of NMP-22 testing to cytology may increase the sensitivity for recurrent detection in patients with superficial transitional cell bladder cancer. Patients with positive NMP-22 findings develop significantly more recurrences compared with those with negative NMP-22 findings in several studies.

**NOCTURNAL ERECTIONS, NORMAL AND ABNORMAL**

Description: Nocturnal erections occur at night during REM sleep. The number of erections peaks during puberty. Various criteria exist for what is considered normal nocturnal activity at night, but normal is usually 4–5 erections per night with a mean duration >30 min and an increase in circumference of >3 cm at the base and >2 cm at the tip, as well as maximal rigidity above 75% at both base and tips. (See also Section II: “Nocturnal Penile Tumescence Testing.”)

**NOCTURNAL PENILE TUMESCENCE (NPT) TESTING**

Description: NPT refers to a recurring cycle of penile erections associated with rapid eye movement sleep. The primary goal of NPT testing is to distinguish between psychogenic and organic causes of impotence; nocturnal monitoring devices measure the number of erectile episodes, maximal penile rigidity, tumescence, and duration of erections. This testing assumes that the mechanism for nocturnal erections is the same as that for sexually induced erections. (See also Section II: “Nocturnal Erections, Normal and Abnormal.”)

**NOCTURNAL POLYURIA (NP) TESTING**

Description: NP is a condition in which the rate of urine output is excessive only at night, and total 24-hr output is within normal limits. NP is defined as the production of >13 of total 24-hr urine output between midnight and 8 AM (normal physiologic response is reduced urine output at night).

**NONARTERITIC ANTIEROSIONIC OCULAR NEUROPATHY (NAION)**

Description: NAION describes the acute, painless loss of vision in 1 eye associated with optic disc edema (crowded optic disk). It is a common cause of acute optic neuropathy in adults. Associations have been found between NAION and the phosphodiesterase inhibitors sildenafil, vardenafil, and others.

**NONSACRAL NEUROMODULATION**

Description: Neuromodulation involves the use of electrical current to alter physiologic properties. This technology has been applied to lower urinary tract dysfunction for the past decade by stimulation of the sacral nerve roots. There has been recent interest into stimulation of more distal branches of the same nerve roots as well, including the pudendal, dorsal genital, and posterior tibial nerves. (See also Section II: “Neurostimulation, Urologic Considerations.”)

**NOONAN SYNDROME**

Description: This autosomal dominant syndrome consists of multiple congenital anomalies, including characteristic facial features, short stature, and heart defect. Over 1/2 of males with Noonan syndrome have unilateral or bilateral cryptorchidism. Females can have delayed sexual maturation, but normal development is expected. Renal anomalies occur in 10% of children. Because congenital cardiac anomalies are found in 1/2 of the patients, all patients with this syndrome should have cardiac evaluation and slow follow-up. Growth hormone replacement may have value in treating short stature.

**N-TELOPEPTIDE, URINARY**

(NTX)

**DESCRIPTION**

NTX is a product of type I collagen breakdown that can be measured in the urine. Several studies suggest its utility as a marker for bone turnover in osteoporosis, and for response to treatment of bone metastases and bisphosphonate therapy. Typical reference ranges are (bone collagen equivalent) BCE(24 h): 26–124 nM BCE/mM creatinine; adult female premenopausal: 17–84 nM BCE/mM creatinine; postmenopausal: 26–124 BCE/mM creatinine. A decrease of 30–40% from the NTX baseline after 3 yrs of therapy is typical for treatment with bisphosphonate.

**REFERENCE**

**NUTCRACKER SYNDROME**

**DESCRIPTION**

This syndrome occurs secondary to compression of the left renal vein by the superior mesenteric artery and the aorta. Patients are usually young and previously healthy. Presentation classically is due to gross hematuria caused by left renal vein hypertension. Pelvic pain may be present. Various modalities, including nephrotomies, autotransplantation, renal neophlebitis, and nephrectomy have been employed. Gom-Test graft renal vein interposition and anterior nephropexy have been successful (Image 9).

**REFERENCE**

The obturator nerve, which is made to trim both segments sharply. In the event of a nerve is frayed and grossly devitalized, efforts can be repair when applied to the new anastomosis. If the approximation. An absorbable collagen implant nerve be made to align the nerve fibers prior to edges with four 6–0 to 10–nylon or Prolene epineural surgical repair may be done by end-to-end intraoperative obturator nerve injury is not well helpful in making the diagnosis. Symptoms include hypertension, diabetes, and vascular disease.

Likewise, this aromatization of androgens leads to conversion of testosterone to estradiol in adipocytes. Obese men is postulated to result, at least partially, by adverse pathology. Renal cell carcinoma (RCC) is also associated with obesity. The increased incidence in prostate cancer in obese men is postulated to result, at least partially, by treatment involves the removal of potentially bladder tumors located on the posterolateral wall, or laparoscopic pelvic lymph-node dissection) can cause unexpected adduction of the thigh. Surgeons must be aware of this response so as not to cause inadvertent injury, such as perforation of the bladder. This response can usually be prevented by muscle-paralyzing anesthetic agents.

O’Leary MP, Sant GR, Fowler FJ Jr, et. al. The O’Leray–Sant Interstitial Cystitis Symptom Index (ICSI) DESCRIPTION The ICSI is a validated questionnaire that documents and scores patient’s questionnaire that documents and scores patient’s symptoms of urinary urgency, frequency, nocturia, and dysuria/pain over a 30-day period. It has been found useful as a tool to follow symptoms of but not the diagnosis of interstitial cystitis.

**DESCRIPTION**
OPITZ-FRIAS SYNDROME
**DESCRIPTION**
Also called the OIF syndrome (named for 1 of the first patients), this condition is due to a defect of midline development, characterized by numerous congenital abnormalities of the face. Many patients have hypertelorism and posteriorly rotated ears, hypogonadism is almost always present. Other manifestations include cleft lip and palate, high trigeminal and facial paralysis, upper extremity syndactyly, microcephaly, anorectal malformations, long hypoplastic, and cardiac abnormalities. Inheritance is autosomal dominant with incomplete penetrance. Carries show minimal abnormalities. It is more common in males, and perinatal mortality is around 30%.

**DESCRIPTION**
OSTEONECROSIS OF THE JAW (ONJ), UROLOGIC CONSIDERATIONS
**DESCRIPTION**
Osteonecrosis is a newly recognized complication of long-term therapy with bone strengthening agents in patients with metastatic cancer to the bone such as prostate, breast and renal cell cancer and in multiple myeloma. Bisphosphonates and denosumab decrease cancer-induced bone resorption thereby reducing SREs, pain, and improving quality of life. Initially identified as an exposure-necrosis multifocal bone for >9 wk in patients treated with bisphosphonates or denosumab who have not had radiation to the jaws. The exposed bone becomes infected with oral flora, resulting in significant pain and need for surgery. A new term is bisphosphonate-related osteonecrosis of the jaws (BRONJ). Symptoms include pain, swelling, redness, or other signs of infection in the gums, ears or cheeks that don’t heal after dental work, loose teeth and numbness or a heavy feeling in the jaw. The risk of developing ONJ is related to the potency of the antiresorptive, the duration of exposure, and demineralized trauma. Prospective studies of patients taking bisphosphonates for metastatic prostate cancer that include regular exam by dentist estimate an incidence as high as 20% which is much higher than retrospective studies that suggested an incidence of 3-4%. Dental clearance before initiating therapy is recommended as well as avoiding extensive dental work while on therapy.

**REFERENCE**
DESCRIPTION
Ovarian cancer is the leading cause of death from gynecologic cancer and is usually of epithelial origin. These tumors can often involve adjacent structures or cause extrinsic compression of the urinary tract, including the bladder and ureters, with the resultant need for urologic intervention.

REFERENCE

OVARIAN REMNANT SYNDROME
DESCRIPTION
This condition is a rare complication of bilateral oophorectomy and occurs when remnants of ovarian cortex are inadvertently left behind. The remaining ovarian tissue becomes functional and cystic. Typically, patients present with pelvic pain that can be chronic or intermittent and a pelvic mass. Symptoms may begin weeks to 5 yr postoperatively. Unusual obstruction has been reported. Excision of the ovarian remnant is the most widely accepted treatment method. Prespective ovarian stimulation can help reproductive identification of retained tissue. Surgery is associated with an 8–10% recurrence rate.

REFERENCES

OVARIAN VEIN SYNDROME
DESCRIPTION
Unilateral obstruction, usually rightsided, occurring secondary to occlusion or dilated ovarian veins. The ovarian veins lie adjacent to the ureters, and dilatation of these veins, especially during pregnancy, is thought to occur in uterine obstruction. The obstruction is usually seen around the L3–L4 vertebral level. Symptoms include chronic flank pain, but uterine pain has also been found. The symptoms can also begin several days prior to menarche and then regress. Diagnosis can be made by IV urogram, retrograde ureteropyelography, and simultaneous angiography. Untreated and ovarian vein exclusion can be performed using open or laparoscopic techniques.

OVARIAN CANCER, UROLOGIC CONSIDERATIONS
DESCRIPTION
Ovarian cancer is the leading cause of death from gynecologic cancer and is usually of epithelial origin. These tumors can often involve adjacent structures or cause extrinsic compression of the urinary tract, including the bladder and ureters, with the resultant need for urologic intervention.

TREATMENT
• Caution: 1,200 mg/d; it is recommended most calcium come from foods (dairy, green leafy vegetables).
• Vitamin D: at least 800–1,000 IU (daily preferable from foods [forty for and intake, liver, raw milk]) with sun exposure of 30 min or supplements.
• Exercise to include weight bearing.
• Stop smoking, limit alcohol and caffeine intake.
• Calcium carbonate: 1–2 g PO Q 4–6 h.

CONSIDER-Biphosphonates:
• Alendronate (Fosamax, Fosamax Plus D) approved for treatment of men with osteoporosis and treatment/prevention of osteoporosis in men taking glucocorticoids.
• Risedronate (Acteon, Alar) approved for treatment of men with osteoporosis and treatment/prevention of osteoporosis in men taking glucocorticoids.
• Pamidronate (Areda) for men with Paget disease, hyperparathyroidism, malignancy, malignant myeloma.
• Zoledronic acid (Zometa): 4 mg intravenously IV approved for bone metastasis but not male osteoporosis.
• Denosumab: (Xgeva) 120 mg SC Q every 4 wk (for osteoporosis).

Oxalate, Dietary
DESCRIPTION
An excessive intake of oxalate-rich foods should be limited or avoided to prevent an oxalate load. This includes fruits and vegetables rich in oxalate such as bean sprouts, kidney beans, and spinach. Some studies have shown that a daily intake of up to 4 g might be allowed without risk. However, a recent study demonstrated an increased risk in stone formation for men taking 1 g/d or more of vitamin C vs. < 0.9 g/d. It is therefore seems justified to advise calcium-oxalate stone formers to avoid excessive intake of vitamin C. (See also Section I: “Urolithiasis, Calcium Oxalate/Phosphate.”) The following products have high oxalate content:
• Rhubarb, 530 mg oxalate/100 g
• Spinach, 570 mg oxalate/100 g
• Cocoa, 625 mg oxalate/100 g
• Tea leaves, 375–1,450 mg oxalate/100 g
• Nuts, 200–450 mg oxalate/100 g

REFERENCES

Oxalate-Associated Renal Disease
DESCRIPTION
Hypersudrosis is associated with calcium oxalate nephrolithiasis. An increased oxalate production or absorption, or an idiopathic form, might be responsible for the disease. In cases of primary hyperoxaluria, stone formation usually starts during childhood, with eventual tubulointerstitial nephropathy and chronic renal failure. Oxalate deposition in heart, joints, and other tissues (oxalosis) may occur. (See Section II: “Hypersudrosis,” for the causes of increased urinary oxalate.)

TREATMENT
• Piroxicam supplements (200–400 mg/d) for primary hyperoxaluria
• Oral hydration; low oxalate, low-fat diet for enteric hyperoxaluria
• Pyridoxine (thiamine) for idiopathic hyperoxaluria

Pyridium 200 mg TID and then change pads every 6 hr for a 24-hr period. The amount of staining is an estimate of hemorrhage. Another approach is to weigh the pads (1 g = 1 mL urine).

REFERENCE

**PAGANO URETERAL ANASTOMOSIS**
DESCRIPTION
A 4–5-cm linear incision is made through the skin of the colon, and the muscularis is dissected from the submucosa to the level of the mesentry. The ureters are pulled through the lateral muscular wall and implanted directly into the mucosa. The ureters are then reapproximated while incorporating muscosa in the midline.

REFERENCE

**PAGE KIDNEY**
DESCRIPTION
This condition was first described in 1909, after hypertension was created by wrapping cellophane around a canine kidney. Applied clinically, this term was given to hypertension secondary to subcapsular or perirenal compression resulting in renal ischemia. Elevated serum creatinine from the compromised kidney and decreased renal production from the contralateral renal unit result. Diagnosis can be made with CT, IV, or MRA, demonstrating a surrounding heterogeneous capsule. Clinical causes include blunt trauma, closed renal biopsy, anticoagulation, or tumor bleed. Treatment is directed at the primary cause. Further therapy may include ACE inhibitors, open or percutaneous drainage, or nephrectomy. Spontaneous resolution can occur secondary to resumption of the hematoma.

REFERENCE

**PAGET DISEASE, ANOGENITAL/EXTRAMAMMARY**
DESCRIPTION
Lymphoplasmacytic leukemia in the epimysium can affect many areas in the body, the mammary gland areas of the body, the mammary glands and may also result from extraneous adenocarcinoma that spread into the epimysium. Evacution of skin lesion and evaluation for underlying malignancy should be performed.

REFERENCE

**PAGET DISEASE, BONE**
DESCRIPTION
This condition affects up to 10% of elderly individuals, with a 3:1 male-to-female ratio. Bone pain is the most common presenting symptom. Paget disease of the spine may also be a cause of low back pain. The disorder is due to increased bone remodeling, bone hypertrophy, and bone deformity of uncertain origin. Paget disease, also called osteitis deformans, is characterized by an initial phase of intense osteoclastic resorption, followed by an increase in bone formation, but the new skeletal tissues are deformed and prone to inducing pain and fracture. Approximately 1/5 of Paget disease cases have monocytic disease, with pelvic involvement in 72%. In these cases, the lumbar spine is involved in 58%, the thoracic spine in 45%, and the femur and skull in 55% and 42%, respectively. Patients’ elevated alkaline phosphatase or bone pain may be due to Paget disease or other diseases, such as liver disease, renal disease, or metastatic prostate cancer. Radiographically, the localized enlargement of bone is a characteristic feature. Areas of lytic due to osteoclastic resorption can also be present. It can be confused with metastatic prostate cancer to bone. Suspect Paget disease over metastatic prostate cancer when there is widening of the bone, thickening of the cortex, and a prominent tubular pattern. MRI of the bone may help in differentiating the processes.

TREATMENT
Pain reduction and decreasing long-term complications are the main goals.
- Inhibitors of osteoclastic bone resorption, such as bisphosphonates (zoledronic acid, risedronate, alendronate) are now the treatment of choice. (See Section II: “Osteoporosis and Osteopenia, Urologic Considerations.”) Calcitonin is reserved for those intolerant of bisphosphonates.

REFERENCE

**PAINFUL BLADDER SYNDROME (PBS)**
DESCRIPTION
The ICS defines PBS as suprapubic pain related to bladder filling, accompanied by other symptoms such as increased daytime and night-time frequency, in the absence of proven urinary infection or other obvious pathology. According to the ICS, PBS differs from interstitial cystitis in that the latter has cystoscopic and histologic findings. Treatment begins with conservative measures including dietary modification, behavioral changes, and nonprescription medications, followed by intravesical therapy and prescription medications. Patients who fail these therapies may resort to more invasive therapies including hydrodistention, neuromodulation, and finally urinary diversion or augmentation.

REFERENCE

**PALLIATIVE RADIATION, UROLOGIC CONSIDERATIONS**
DESCRIPTION
The symptoms of advanced urologic malignancies are often treated with palliative radiation. Approximately 1/2 of prescribed radiation is given for palliation of symptoms from incurable cancer. For example, 90% of patients with symptomatic bone metastases, commonly seen in metastatic prostate cancer, obtain some pain relief with a low-dose, brief course of palliative radiation. Bone metastases can also result in erosion of cortical bone and tumor invasion into the extraspinal space, which affects either within the spinal cord and compression of the neurologic structures. The degree of edema within the cord is directly related to the neurologic impairment. Spinal cord compression from malignancy requires early diagnosis and treatment with emergency surgery to prevent irreversible neurologic injury. Radiation therapy has also been shown to relieve clinical symptoms in 75–90% of patients with bone metastases, sometimes seen in patients with metastatic RCC.

REFERENCE

**PANCREATITIS, AUTOIMMUNE UROLOGIC CONSIDERATIONS**
DESCRIPTION
Autoimmune pancreatitis (AIP) has been referred to by a variety of names including sclerosing pancreatitis, tumorlike pancreatitis, and nonalcoholic obstructive pancreatitis. It is recognized to be an idiopathic, chronic, inflammatory disorder of the pancreas (IgG4-RD). IgG4-related kidney disease can include tubulointerstitial nephritis and membranous glomerulonephritis.

REFERENCE

**PANETH CELL-LIKE CHANGE, PROSTATE**
DESCRIPTION
Paneth cell metaplasia of the prostatic epithelium, due to the presence of PSA and PAP on immunohistochemistry. These changes have been described in normal, hyperplastic, dysplastic, and malignant prostate tissue, and must be differentiated from other pathology.
Prostatic intraepithelial neoplasia including secretory vessels, induration, CIN-like areas, or viral-like particles.

REFERENCE

PAPILLARY UROTHELIAL NEOPLASM OF LOW MALIGNANT POTENTIAL (PUNLMP)

DESCRIPTION
The World Health Organization defines PUNLMP as a papillary urothelial tumor that resembles an exophytic urothelial papilloma, but shows increased cellular proliferation exceeding the thickness of normal urothelium. They are typically small (1–2 cm) and have little or no, cystic atypia. Treatment and follow-up are the same as for low-grade noninvasive urothelial carcinoma. (See also Section II: “WHO/ISUP Classification of Urothelial Neoplasms” [1998 and 2004].) (Image 90)

REFERENCE

PAPILLORENAL SYNDROME

DESCRIPTION
Also called renal condrum, this is an autonomic dominant disorder characterized by bilateral congenital optic disc anomalies and hypoplastic kidneys. It is associated with mutations in the PK2X gene. Many patients suffer from renal failure due to renal hypoplasia or chronic pyelonephritis from urothelial reflux.

REFERENCE

PAQUIN URETERAL REIMPLANTATION

DESCRIPTION
This repair is done using combined extravesical ureteral mobilization and intravesical implantation. A submucosal plane is developed extravesically ureteral mobilization and intravesical implantation. A submucosal plane is developed

REFERENCE

PARAPHILIAS, UROLOGIC CONSIDERATIONS

DESCRIPTION
Paraphilias are psychosocial concerns related to abnormal sexual behavior. These may be encountered in daily urologic practice and are often referred for psychological intervention. Different kinds of paraphilias, based on the Diagnostic and Statistical Manual of Mental Disorders, 4th ed, Text Revision (DSM-IV-TR) classification are noted in the accompanying table.

SYNONYM
Sexual Deviation

Paraphilia Designation Description
Exhibitionism Exposure of genital to unsuspecting strangers (not considered the same as public nudity).
Fetishism Use of nonliving objects as repeatedly preferred or exclusive method of sexual excitement (eg, leather goods, clothing, undergarments, fabrics, shoes). Of female clothing is used in cross-dressing or devices are used for genital stimulation (eg, vibrator) this is not considered as fetishism.
Frottiration Touching and rubbing against a nonconsenting person.
Pedophilua Children are the sexual target (perpetrator is ≥16 yo and ≤5 than 5 years older than the prepubescent child).
Sexual masochism Perpetrator receives the humiliation/suffering can lead to death, especially during “hypoxyphilia” or sexual arousal during hypnosis.
Sexual sadism Perpetrator inflicts the humiliation/suffering on another.
Transvestic fetishism Wearing clothing of the other sex for sexual arousal.
Voyeurism Observing sexual activity or naked/dressing individuals.
Paraphilias: Not Otherwise Specified

REFERENCE

PARASTOMAL HERNA

DESCRIPTION
A parastomal hernia is an incisional hernia related to an abdominal wall stoma. In urologic surgery, parastomal hernias occur infrequently (<1–3% of cases) and are more likely to arise in low-type stoma than in end-type stoma. To prevent parastomal herniation, it is recommended that the stoma be placed through the rectus muscle and that the opening in the abdominal wall not be too large. In addition, some have placed mesh at the time of stoma creation to prevent hernia formation. Repair of a parastomal hernia follows the same principles as treating other types of incisional hernias and can be completed in an open or laparoscopic fashion, with or
without mesh. (See also Section I: "Urostomy Problems.")

REFERENCE

PARATESTICULAR RHABDOMYOSARCOMA

DESCRIPTION

Rhabdomyosarcoma is the most common sporadic childhood cancer, arising from the mesenchymal elements of the paratesticular tissues and representing 40% of all paratesticular malignancies and 5% of all testicular and paratesticular malignancies. There is a bimodal age distribution, peaks at 3–4 mo and 16 yr. Patients present with a painless firm mass which can be a wide range of sizes. Roughly 40% have metastases at presentation. Ultrasound reveals a heterogeneous mass. CT scan of the abdomen and pelvis, liver function tests, bone scans, and chest x-ray are required for staging. Several histologic patterns are described, with almost all being embryonal. After treatment, cross-sectional imaging and liver function tests are needed every 2–3 mo. (See also Section I: "Urothelial Paratesticular Tumors and Cysts."

TREATMENT

• Radical orchectomy.
• Boys 10 yr or older with evidence of retroperitoneal disease should undergo retroperitoneal lymph node dissection (RPLND).
• Those with evidence of lymph node spread undergo adjuvant therapy and multigland chemotherapy.

REFERENCE

PARAURETHRAL AND VAGINAL WALL MASSES

DESCRIPTION

Paraurethral masses can be benign (urothelial caruncles, Simee’s gland abscesses, vesical prolapse, acdotic watermelon, urethral diverticulum, vaginal wall cyst, Gartner’s duct cyst, leiomyoma, hamartoma or malignant) (adenocarcinoma, SCC, TCC, histiocytoma, and melanoma), and can be classified according to the location of the lesion. The most common paraurethral mass is the urethral diverticulum, followed by the leiomyoma and the vaginal wall cyst. Masses may be asymptomatic or particularly for masses causing voiding dysfunction. Physical exam may help distinguish benign from malignant lesions. Paraurethral malignancies do not normally present as paraurethral masses, but more commonly with complaints of bleeding and discharge.

REFERENCE

PARTN TABLES

DESCRIPTION

Nomograms for patients with biopsy-proven prostate cancer, developed by Dr. Partin and associates at Johns Hopkins University, these charts incorporate PSA, TMM stage, and Gleason score. They are used to predict rate of lymph node and distant spread or whether patients have organ-confined cancer, and to aid in making accurate treatment decisions. The tables have been updated several times, using larger patient cohorts. Information is available online: http://urology.jhu.edu/prostate/partintables.php. Accessed March 3, 2014.

REFERENCE

PATAU SYNDROME

DESCRIPTION

This rare syndrome is associated with trisomy 13 and has a median survival of 3 mo. The incidence is 1 in 6,000 live births and is associated with multiple cardiac, neurologic, and renal abnormalities. Renal anomalies occur in about 80% of children. Unilateral renal agenesis, renal duplication, hydrouphrosis, and polycystic kidneys have been associated with Patau syndrome.

REFERENCE

PATIENT PERCEPTION OF BLADDER CONDITION (PPBC)

DESCRIPTION

The Patient Perception of Bladder Condition (PPBC) is a questionnaire that attempts to obtain a global assessment of the patient’s bladder condition. It has been validated and shown to be responsive to changes. It has been translated into many languages and is widely available for use.

Which of the following statements describes your bladder condition best at the moment? Please mark X in 1 box only.

- My bladder condition does not cause me any problems. (0 pt)
- My bladder condition causes me some minor problems. (1 pt)
- My bladder condition causes me some moderate problems. (2 pt)
- My bladder condition causes me some severe problems. (3 pt)
- My bladder condition causes me (some) severe problems. (4 pt)
- My bladder condition causes me (none) moderate problems. (5 pt)
- My bladder condition causes me severe problems. (6 pt)

REFERENCE

PATENT PERCEPTION OF INTENSITY OF URGENCY SCALE (PPUIS)

DESCRIPTION

A simple question tool to assess the patient’s perception of the degree of urgency. PPUIS as a reliable measure of urgency in both clinical trials and real life settings. The question is as follows:

Patient Perception of Intensity of Urgency Scale

0. No urgency. I felt no need to empty my bladder but did so for other reasons.
1. Mild urgency. I could postpone voiding as long as necessary without fear of wetting myself.
2. Moderate urgency. I could postpone voiding for a short while without fear of wetting myself.
3. Severe urgency. I could not postpone voiding but had to rush to the toilet in order not to wet myself.

REFERENCE

PC2A (PROSTATE CANCER GENE 3 URINE ASSAY)

DESCRIPTION

Prostate cancer antigen 3 (PCA2) is a gene that expresses a noncoding RNA. PCA2 is over expressed in 95% of prostate cancers and is upregulated 64-fold in cancerous tissue as compared to normal tissue. No other human tissues have yet been shown to produce PCA2. While serum PSA levels are known to be influenced by volume of BPH tissue, age, inflammation, trauma, and use of 5α-reductase inhibitors (finasteride, dutasteride), preliminary data indicate that these factors do not appear to influence PCA2 scores. Urine samples are collected after an “attention” digital rectal exam (5 swipes on each side of the prostate), 1st voided urine is then collected and sent to labs for analysis. PCA2 and PSA can be detected in the urine utilizing reverse transcriptase PCR techniques on the collected cells. PCA2 expression is detected against a background of prostate specific genetic material, a PCA2 score (a ratio of PCA2 to PSA mRNA). Studies have shown excellent specificity and sensitivity in men undergoing confirmatory prostate biopsy, and its role in the diagnosis of prostate cancer is currently evolving. A useful role of the new marker appears to be in men with persistently elevated serum PSA levels, but a negative initial biopsy.

PELARY PAPERIES OF PENIS

DESCRIPTION

These are normal anatomic structures located on the proral genital penis or corona. They appear as minute, dome-shaped, flesh-colored papules. The incidence is 1%–10%. These lesions are asymptomatic and can be confused with genital warts. Histologically, these papules are angio-architecture, his treatment is usually needed. Although these lesions represent a bane condition, psychological and social consequences often prompt patients to seek therapeutic removal. Multiple therapeutic modalities have been reported; however, removal of CO2 laser has proven to be the most effective to date.

REFERENCE

PELARY PAPERIES OF PENIS (PELLARY PAPULIES OF PENIS)

DESCRIPTION

Acute kidney injury (AKI) is defined as a decrease in GFR, manifested by an elevated or rising creatinine. However, serum creatinine is a delayed and insensitive test as it reflects GFR in individuals at steady state with stable kidney function, and may not estimate the GFR in a patient whose renal function is changing. Recognizing a need for a criteria definition of AKI called the RIFLE classification of AKI based on changes in creatinine and urine output were developed. The RIFLE criteria consists of 3 graded levels of injury (Risk, Injury, and Failure) based upon either the magnitude of elevation in serum creatinine or urine output, and 2 outcome measures (loss and End-stage renal disease). This is a pediatric modification of the adult RIFLE classification (see table). The urine of RIFLE has been strongly advocated as a research and clinical tool. AKI defined by the RIFLE criteria has been shown to be an independent risk factor for mortality and morbidity. (See also Section I: “Acute Kidney Injury, Pediatric”).

PEDIOLYSIS PUBIS (CRAB LICE/PUbic LICE)

DESCRIPTION

Ectoparasitic infection (Phthirus pubis), marked by severe pruritus and tending to have an incubation period of 4 wk. Signs include observation of the lice, 1–2 mm long gray-brown organisms, on the skin or on the hair shaft or the presence of “nits” (egg stage) on the hair shaft. The recommended regimens should not be applied to the eyes. Pediculosis of the eyelashes should be treated by applying occlusive ophthalmic ointment to the eyelid margins twice a day for 10 days. Bedding and clothing should be decontaminated (i.e., dry cleaning or machine-washed and dried using the heat cycle) or removed from body contact for at least 72 hr. Fumigation of living areas is not necessary. Nits need to be mechanically removed with a fine-toothed comb. Patients with pcsiolysis pubis should be evaluated for other STIs/TDs. Patients should be evaluated after 1 wk if symptoms persist. Prevention might be necessary if the host are found or if eggs are observed at the hair skin junction. Patients who do not respond to 1 of the recommended regimens should be retreated with an alternative regimen. Sex partners that have had sexual contact with the patient within the previous month should be treated. (See also Section II: “Sexually Transmitted Infections (STI)” Sexually Transmitted Diseases (STD), general.”)

TREATMENT

CDC-recommended regimens: Permethrin 1% cream rinse applied to affected areas and washed off after 10 min OR Pyrethrins with piperonyl butoxide applied to the affected area and washed off after 10 min

CDC Alternative Regimens: Malathion 0.5% lotion applied for 8–12 hr and washed off OR Ivermectin 250 μL/kg orally, repeated in 7 wk

PELVIC FLOOR DYSFUNCTION

DESCRIPTION

Pelvic floor dysfunction represents a constellation of symptoms that include lower urinary tract, bowel, sexual, and other local symptoms, including pelvic organ prolapse. These conditions are all associated with damage to the pelvic floor through disruption of the connective tissue or by primary or secondary neuropathy and hypotrophy. Many predisposing, initiating, and promoting factors can lead to pelvic floor dysfunction. Treatments range from conservative/biologic therapies, to medications and surgical considerations.

REFERENCE

PELVIC FRACTURE, UROLOGIC CONSIDERATIONS

DESCRIPTION

Pelvic fractures can result in bladder and urethral injury. The length and tethered anatomy of the male urethra makes it more vulnerable to injury. Blood at the urethral meatus is the cardinal sign of urethral injury. For patients suspected of having a urethral injury, a retrograde urethrogram should be performed prior to insertion of a Foley catheter. This should be followed by a cystogram. Depending on the location and extent of trauma, several options exist for treatment including drainage of the bladder with a Foley catheter or suprapubic cystostomy, primary repair of the injury, or delayed repair after stabilization. (See also Section I: “Urinary Trauma (Anterior AND Posterior).”)

REFERENCE

PELVIC LIPOSARCOMA

DESCRIPTION

Pelvic liposarcoma can present as a tumor of the spermatic cord or as a parasacral tumor. Treatment includes ipsilateral orchidectomy with high ligation of the cord, adjunct treatment is controversial but could include postoperative
PELVIC PAIN, MALE

DESCRIPTION

Bacterial prostatitis or prostatitis syndrome (BPH) is a chronic inflammatory condition of the prostate gland.

REFERENCES

PELVIC ORGAN PROLAPSE QUANTIFICATION SYSTEM (POP-Q)

DESCRIPTION

A quantitative description of pelvic support using the hymenal ring as the reference point. Negative numbers are assigned to structures that have prolapsed beyond the hymen, and positive numbers to those that are protruding. Three reference points are defined anteriorly and 3 points posteriorly. Once the measurements are complete, the patient is assigned to 1 of 4 stages as noted below.

Stage

0

No prolapse demonstrated

I

The most distal portion of the prolapse is > 1 cm above the level of the hymen

II

The most distal portion of the prolapse is ≤1 cm proximal or distal to the hymenal plane

III

The most distal portion of the prolapse protrudes > 1 cm below the hymen but protrudes no further than 2 cm less than the total vaginal length

IV

Complete vaginal eversion

REFERENCE

PELVIC PAIN AND URGENCY/FREQUENCY (PUF)

PATIENT SYMPTOM SCALE

DESCRIPTION

Instrument for the evaluation and treatment of patients with interstitial cystitis (IC)/Painful Bladder syndrome (PBS). See also Section I: "Pelvic Organ Prolapse/Enterocele."

REFERENCES

PELVIS, BIFID, RENAL

DESCRIPTION

A normal variant seen in ~10% of patients in which the renal pelvis is divided into 2 major calyces just inside the kidney. See Pelvis, bifid, renal (Image E)

REFERENCE

PELVIS, EXTRARENAL

DESCRIPTION

Most often a normal anatomic variant that can be mistaken for a pathologic condition (hydronephrosis, parapelvic cyst, or renal cyst, etc.). Calyces are normally appearing on imaging with an unstructured extrarenal pelvis but will be blended with the extrarenal pelvis. The extrarenal pelvis can also be associated with conditions such as renal visualization or ectopic kidney and rarely may cause urinary stasis and difficulties with infection and stones.

REFERENCE

PELVIC BRACHIAL PRESSURE INDEX (PBI)

DESCRIPTION

The PBI can be defined as the pelvic systolic BP divided by the brachial systolic BP. A pelvic-brachial index of ≤0.7 has been suggested to indicate arteriogenic impotence. However, due to several limitations, this test is considered an unreliable tool to exclude arteriogenic impotence.

REFERENCE

PELVIC DOPPLER ULTRASOUND INDICATIONS AND PARAMETERS

DESCRIPTION

This type of minimally invasive urologic imaging is used for men with ED who have a potentially surgically treatable cause (eg, young men who may have suffered traumatic perineal injuries and do not respond to oral or intracavernous therapy). Pelvic Doppler US is used for evaluation of pelvic blood flow and requires intravesical potassium sensitivity. Peak systolic velocity (PSV) in healthy individuals varies from 35–47 cm/s. A PSV <25 cm/s has a sensitivity of 100% and specificity of 95% in patients with abnormal functional arteriopathy. Patients with severe ED will have a cavernous artery luminal diameter ≤0.7 mm and an increase of >75% in diameter post-injection. Patients with evo-occlusive dysfunction will exhibit good PSV (>25 cm/s) and have persistent end diastolic flow velocity of <5 cm/s with quick detumescence after stimulation. A resistive index calculation (RI = EDV – ESV/PSV) >0.9 (where EDV is end-diastolic velocity) usually indicates no evidence of evo-occlusive dysfunction, whereas an RI of <0.75 was associated with venous leakage in 95% of cases.

REFERENCE

PELVIC ENHANCEMENT AND LENGTHENING

DESCRIPTION

Penile lengthening can be accomplished by release of the suspensory ligament of the penis and the use of penile weights. Increased girth can be obtained by the use of circumferential dermal fat grafts. There are reports of significant complications from lengthening and girth procedures including scarring, skin deformities, irregular fat deposits, chronic enlargement of the penis, and ED.

REFERENCE

Penile Prosthesis

DESCRIPTION

Penile prosthesis is considered for men whose erectile function is nonresponsive to medical or psychological aids and is seriously disabling. Various models are available with the majority used inflatable units. They are in 3 categories: Semi-rigid, 2-piece, and 3-piece inflatable (see table) (Image 1). The earliest attempts of implantable devices began in the 1930s with the 1st successful prosthesis in 1955. Prosthetic devices have been improved in design and materials over the years to aid erectile function recovery after RP.

Penile Prosthesis, Models and Descriptions

REFERENCE

Penile Shortening

DESCRIPTION

Penile shortening may occur congenitally in patients with bladder exstrophy and more commonly after radical prostatectomy (RP) and penile revascularization surgery. Patients with bladder exstrophy have penile shortening because of diastasis of the pubic symphysis and short corporal lengths (<40% the size of controls). More commonly, patients may have shortening of the penis following RP because of unopposed sympathetic stimulation of the penis, fibrosis resulting from hypogonadism (as a consequence of denervation), or possibly as a result of revascularization of the penile structures into the pelvic. Treatment of Peyronie disease may result in minor penile shortening. Amelioration of this side effect by revascularization surgery for vascular ED may result in penile shortening in 20% of patients as a result of scar formation. In a prospective study of stretched flaccid penile length changes after RP, there was evidence of stretched flaccid penile length loss at 2 mo, but not at 6 mo after RP. PDE5 inhibitors increase stretched flaccid penile length loss, with patients who regularly used PDE5 inhibitors having no loss in stretched flaccid penile length.

REFERENCE

PENIS, AGNATHOSARCOMA

DESCRIPTION Approximately 12 cases of penile angiosarcoma have been reported. No site of predilection is demonstrated, and the tumor may be well-margined or ill-defined. Deaths may occur 1 wk to 5 yr after presentation (mean = 1.1 yr). The application of immunoperoxidase staining for factor VIII, present in normal endothelial cells, aids in diagnosis.

TREATMENT
- Local excision with lymph node dissection
- Radiation therapy
- Systemic chemotherapy with more widespread disease

REFERENCE

PENIS, ANGIOSARCOMA

DESCRIPTION Tumors are vascular neoplasms, followed by tumors of soft tissue. These tumors can be classified as benign or malignant, most have been reported as isolated case reports. The management varies considerably. (See also Section II: Soft tissue tumors of the penis: a review.)

REFERENCE

PENIS, ARTIFICIAL NODULES (TANCHO NODULES, BULLETS, FANG MUK, CHAGAN BALLS)

DESCRIPTION Sarcoïd nodules are spherical foreign objects, in the form of beads, implanted in the subcutaneous tissue of the shaft of the penis proximal to the glans. They are placed to allegedly enhance the sexual pleasure of females during sexual intercourse. It is a practice common in southeast Asia, especially Thailand. However, non-Asian groups in Romania, Russia, and Middle East have adopted this practice as well. The incidence and severity of early or delayed complications are unknown but are probably underestimated.

REFERENCES

PENIS, BASAL CELL CARCINOMA

DESCRIPTION Basal cell carcinoma is a common cutaneous malignancy, but it is very rare at the penis. Ultraviolet radiation is an important risk factor. Basal cell carcinoma of the penis most likely presents in the 5th–7th decades of life. The natural history is that of a slowly growing tumor with little propensity to local destruction, including superficial excision, laser surgery, and use of topical retinoid acid, podophyllin resin, and topical 5-fluorouracil. The recurrence rate is 20%.

REFERENCES

PENIS, BOWENOID PAPULOSIS

DESCRIPTION Bowenoid papulosis of the penis is a benign lesion that appears as rounded, reddish, single, or multiple papules on the glans or shaft of penile skin, although they can occur anywhere on the external genitalia or perianal regions of both males and females. These papules typically occur in sexually active women who are 25–35 yr of age. They are caused by HPV and maybe confused with carcinoma in situ (CIS) of the penis. Histologically, these lesions show parakeratosis and acanthosis in squamous epithelium with disorganization of the epithelial cells.

REFERENCES

PENIS, BURIED (CONCEALED/ HIDDEN/ TRAPPED)

DESCRIPTION This condition must be differentiated from an abnormally small penis. A buried or concealed penis refers to a normal-sized penis that is hidden because of the prepuce fat pad. Congenital causes or obesity can hide the penile shaft. The penis can usually be exposed by retracting skin lateral to the penile shaft. The intraurethral hidden penis after circumcision is more properly called a trapped penis. Children who undergo circumcision with testosterone swelling or with a hernia or a webbed penis are at risk for excess penile shaft skin loss and a trapped penis. Congenital buried penis is a spectrum characterized by a longer inner prepuce and may include in addition; short penile shaft; abnormal attachment of hamular, and suspensory ligaments; and excess supra-pubic fat. Congenital mega prepuce (OMAP) is a variant. Theoretically, obese adults who undergo circumcision are also at risk for removal of excess shaft skin. Symptoms can sometimes be associated (baldness, LUT, painful inguinal, ballooning of the foreskin, and urinary retention) with the condition.

SYNONYM
Inconspicuous penis (general term for buried, trapped, or webbed penis)

TREATMENT
- Surgery is the treatment of choice in patients with symptoms or complications.
- Laser therapy has been successful in some cases.

REFERENCES

PENIS, CUTANEOUS HORN

DESCRIPTION Cutaneous horn is a clinical diagnosis referring to a conical projection above the skin that resembles a miniature horn. The lesions usually arise in sun-exposed skin and are benign. Penile cutaneous horn is rare and is characterized by overgrowth of epithelium above a lesion that may be a wart, nodule, or tumor. It is important to note that the incidence of SCC is 33% when penile horn is present.
**PENIS, CYSTS**

- **Penile hemangiomas** are rare, occurring in 1% of all patients with hemangiomas. They should be differentiated from cutaneous hemangiomas, which are more common and tend to involute with time. By contrast, penile hemangiomas tend to become larger and may require surgical intervention. The physical exam often does not reveal the extent of the lesion, and ultrasound or angiography should be performed to delineate the anatomic. Treatment is surgical excision or laser ablation.

**SYNONYMS**
- Cutaneous hemangiomas
- Subcutaneous hemangiomas
- Penile hemangiomas

**TREATMENT**
- Surgical excision or laser ablation.

**REFERENCE**

**PENIS, HIRSUTE PAPILLOMA (PEARLY PENILE PAPULES, CORONAL PAPILAE)**

**DESCRIPTION**
Hirsute papillomas of the penis, more commonly known as pearly penile papules, are asymptomatic acral angiofibromas, typically distributed circumferentially on the corona and sulcus of the glans penis. The lesion is often confused with 151/155 D, and persists through life, gradually becoming less noticeable with increased age. Treatment is not required, but sometimes offered for cosmetic reasons. CO2 laser is effective.

**REFERENCE**

**PENIS, HYPOPLASIA**

**DESCRIPTION**
A small or hypoplastic penis may be the result of genital tract deficiency, hypoplasia, or epispadias. (See Section I: “Micro penis.”)

**REFERENCE**

**PENIS, KAPOSI SARCOMA**

**DESCRIPTION**
Kaposi sarcoma of the penis is rare, with only 37 cases reported in literature. Amongst those most are associated with HIV, cases do not have been described in immunocompetent patients. It is clinically identified by painless, red-violaceous nodules, as well as pearly plaques, and wart-like pedunculated lesions. The lesions are most commonly found on the glans, although the foreskin, urogenital meatus, and scrotum can also be affected. Treatments described include local surgery, radiotherapy, electroscaupulation, laser, and injection of interferon-α into the lesion. (See also Section I: “Penis, Lesion, General.”)

**REFERENCE**

**PENIS, LEIOMYOMA**

**DESCRIPTION**
Penile leiomyoma is a rare benign tumor of smooth muscle that commonly involves the shaft, with glans penis involvement being less frequent. The lesions tend to be small (1 cm in diameter), well-circumscribed, rubbery in consistency, with light yellow to white cut surface. Electron microscopy and immunohistochemistry should be used to confirm diagnosis. Multiple recurrences are rare. Primary excision of the tumor is the treatment of choice.

**REFERENCE**

**PENIS, LEIOMYOSARCOMA**

**DESCRIPTION**
Penile leiomyosarcoma is a very rare malignant smooth muscle tumor that usually occur on the fifth to seventh decades. Superficial lesions commonly arise from the dermis of the shaft or the smooth muscle of the glans penis and usually form subcutaneous nodules. Deep leiomyosarcoma is less common, arising from the smooth muscle of the corpora cavernosa, and tends to invade the urothelium and metastasize early. These tumors are firm, gray-white, lobulated, and poorly circumscribed, and can range in size from 3–8 cm. Electron microscopy and immunohistochemistry should be used to confirm diagnosis.

**TREATMENT**
- Primary excision of the tumor is the treatment of choice in low-grade (superficial) tumors; however, the tumor tends to recur locally.
- In high-grade (deep) malignancies, the treatment depends on the age of the patient, size, location of the tumor and the degree of invasiveness.

**REFERENCE**

**PENIS, LENGTH, NORMAL**

**DESCRIPTION**
Data on pediatric penile length considerations are discussed in Section I: “Micro penis (Micro penis).” At birth, dimensions of the normal term infant phallic are 3.5 ± 0.7 cm in stretched length and 1.1 ± 0.2 cm in diameter. In adults, concerns over phallic size can direct some men to seek penile augmentation. There is no real delineation between normal and abnormal, since many variables (fat pad, erect vs. flaccid length) are present. For example, a large fat pad can cause a penis to become buried and give a shorter appearance. (See Section II: “Penis, Buried (Concealed).”)

**REFERENCE**
PENIS, STRANGULATION

DESCRIPTION A malignant nerve sheath tumor arising from Schwann cells that very rarely occurs on the penis. These tumors most commonly occur on the dorsal aspect of the penis, near the dorsal nerve. Paraffinomas result from injection of paraffin, petroleum jelly, bear grease, or other materials into penile shaft, in an attempt to increase penile girth. Injections of oil-based substances may also be performed for therapeutic or cosmetic purposes, but these procedures are usually performed by the patient or an untrained person practicing medicine fraudulently. Complications usually occur, including penile deformity, skin necrosis, ED, and painful intercourse (Image 49).

TREATMENT
- Complete excision
- Careful follow-up for recurrence
- Recurrent schwannomas may require total penectomy

REFERENCE

PENIS, SCLEROSING LYMPHANGITIS

DESCRIPTION Sometimes referred to as Mondor phlebitis of the penis, these are thin and often asymptomatic subcutaneous cordlike swellings along the dorsal shaft of the penis or around the coronal sulcus. They can be confused with lymphangitis circumscriptum, a uncommon tumor of the lymphatic channels. The lesion is caused by thickening or thrombosis of the superficial veins of the penis, probably secondary to trauma. Treatment is not usually necessary, and the condition usually resolves in several weeks. Avoid vigorous sexual activity. Failure to resolve in a timely manner may require biopsy.

REFERENCE

PENIS, SCLEROSING NONVENEREAL LYPHANGITIS

DESCRIPTION Penile stricture is caused by attachment of and encircling by a foreign object around the penis, which leads to entrapment and distal ischemia. These efforts are usually associated with an attempt to maintain a longer erection and sexual interest. Foreign objects used include iron rings, rubber bands, steel washers, and strings. Wearing constraining rings on the flaccid penis often result in the impossibility of their removal after erection, leading to vascular complications usually within a few
PENIS, SYRINGOMA

Description: Syringomas are benign apocrine tumors that normally occur in adolescents on the face, neck, axillae, or abdomen. They are extremely rare on the penis; only 6 cases have been reported in the literature to date. On exam, a cordlike structure is palpated. Doppler US can demonstrate a noncompressible portion of the lesion. Therefore, it is crucial to perform a punch biopsy to determine whether the lesion is a syringoma or an appendageal tumor. A punch biopsy can be obtained to relieve patient hours of discomfort and to avoid the need for a transabdominal exposure. Through a transvaginal incision, the bladder neck and perirectal tissue are exposed. The syringoma is passed through a suprapubic stab incision and, under digital guidance, delivered through the perineal tissue. The bladder neck is then suspended with absorbable suture.

PERINEAL GROOVES

Description: Perineal groove is a rare congenital malformation characterized by a wet sulcus lined by mucous membranes, extending from the posterior fourchette to the anterior edge of the anus. There are 2 reasons for surgical correction: cosmetic reasons and the groove mucosa is often infected due to colonization by rectal germ. Patients present with inflammatory aspects of the groove mucosa, infection of the external genitalia, and urinary tract infection. Considering that infectious complications occur in about 50% of patients, surgical excision is often recommended. Generally, the tissue defect is closed by interrupted sutures and some advocate the use of surgical glue over the suture line to help prevent infection/movement of the skin edges and, therefore, the development of subsequent delamination.

PERINEAL MASS

Description: Perineal masses are classified as either benign in malignant and can arise from the perineum directly or from pelvic extension of gastrointestinal, genitourinary, or gynecologic structures. Benign conditions include soft tissue masses, traumatic, or iatrogenic, and infections leading to abscess formation, various fibrosis, genitourinary masses, vaginal and anorectal fistulae. Benign masses are generally limited in size and do not cause symptoms. Malignant tumors that present as a perineal mass include squamous cell carcinoma as well as malignancies of the prostate, urethra, anus, vagina, and metastases from other pelvic structures.

DESCRIPTION
According to the ICS, function (image choice with the aim of negative resection margins form of wide local excision, is often the treatment of origin, extent, and radiologic features of the lesion. Cross-sectional imaging, with CT scan or MRI, is usually required to further define the anatomic origin, extent, and radiologic features of the lesion. Aggressive surgical treatment of mass lesions, in the form of wide local excisions, is often the treatment of choice with the aim of negative resection margins without causing disturbances to urinary or anorectal function (Image 10).

REFERENCES

PERINEAL PAIN, DIFFERENTIAL DIAGNOSIS
DESCRIPTION
According to the ICS, perineal pain syndrome is the occurrence of persistent or recurrent episodic perineal pain which is either related to the micturition cycle or associated with symptoms suggestive of urinary tract or sexual dysfunction. Perineal pain is felt in the female, between the posterior fourchette (posterior lip of the introitus) and the anus. There is no proven infection or other obvious pathology. The ICS suggests that in men, the term prostatodynia (prostate-pain) should not be used as it pathologic. The ICS suggests that in men, the term prostatodynia (prostate-pain) should not be used as it pathologic.
PERIURETERITIS

DESCRIPTION
Most cases of periureteritis, or inflammatory changes surrounding the ureters, are secondary to infection from microorganisms that cause infections elsewhere in the genitourinary tract. Any associated anatomic abnormality of the ureters, including strictures, megareter, and ureterocolic, predisposes an individual to ureteritis. Urinary obstruction, trauma, and adenomucinous obstruction are other causes for periureteral inflammation. The 1st step in treatment of periureteritis is treating the underlying etiology, including the treatment of infection, stricture, stone, or tumor. This step is not used in most cases of periureteral inflammation.

REFERENCE

PERITONEAL ABSCESES

DESCRIPTION
A life-threatening infection of the peritoneum and peritoneal tissues that can spread rapidly to the adjacent soft tissues. It most commonly presents with peritoneal irritation (94%), fever (70%), urinary retention (39%), a draining abscess (11%), dysuria, and urethral discharge. Peritoneal abscesses have often been associated with gonococcal urethritis infections, urethral strictures, perineal bulking agent injections, and urethral diverticulitis. Drainage and broad spectrum antibiotics are the mainstay of treatment.

REFERENCE

PERLMAN SYNDROME

DESCRIPTION
An overgrowth syndrome characterized by fetal gigantism, visceromegaly, distinct facial features, and nephropathosis. Similar overgrowth syndromes include Beckwith–Wiedemann, Sotos, and the Simpson–Golabi–Behemel syndromes. Neonatal mortality is extremely high. The kidneys are often dysplastic, with numerous cysts and nephroblastomatosis. The cause is unknown, and the diagnosis is based entirely on the phenotypic description.

REFERENCE

PHIMOSIS, CLITORAL

DESCRIPTION
Phimosis should be suspected in women with clinical pain, itching, or burning. A physical exam may reveal a mild, moderate, or severe degree of an inability to visualize the entire clitoris. Initial conservative treatment involves testosterone and estrogen cream to improve the elasticity of the prepuce and potentially antifungal agents such as nystatin or fluconazole. Rarely, when phimosis may result in a white scarring of the clitoris, prepuce, and perineum. Treatment with distal clitoral skin can improve symptoms. Women with respiratory symptoms may require a dural slit.

REFERENCE

PHOSPHATE NEPHROPATHY, ACUTE

DESCRIPTION
Acute phosphate nephropathy is characterized by acute and subsequent chronic renal failure following exposure to oral sodium phosphate (OSP) bowel purgatives. Renal biopsy demonstrates acute and chronic tubular injury with prominent tubular and interstitial calcium phosphate deposits. Risk factors include older age, female gender, hypertension (HTN), chronic kidney disease (CKD) and treatment with angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers, and diuretics. The pathologic mechanism of action involves hypercalciuria-induced proximal salt and water reabsorption, delivery of a large phosphate load to the distal nephron, and precipitation of calcium phosphate in the distal tubule and collecting duct. Prevention of acute phosphate nephropathy is best achieved by avoiding sodium phosphate purgatives in high risk patients, aggressive hydration, minimizing the dose, and maintaining a minimum of 12 hr between administrations.

REFERENCE

PINWORMS, UROLOGIC CONSIDERATIONS

DESCRIPTION
Approximately 209 million people are infected with intestinal pinworms (Enterobius vermicularis) worldwide. They most commonly reside in the large intestine, and females lays by ∼15,000 eggs nightly on the perineum, causing intense perineal itching and sleep disturbances. Occasionally, worms may ascend the vagina and enter the urinary bladder through the fallopian tubes, where they may lay eggs causing an intense inflammatory response resulting in fever, abdominal pain, adhesions, and granulomas. Involvement of the urinary tract is rare, and only 1 report exists of E. vermicularis in the bladder.

TREATMENT
- Mebendazole 100 mg PO once (1st-line) or pyrantel pamoate 11 mg/kg up to 1g PO once (2nd-line)
- Nonsteroidal anti-inflammatory drugs
- Clean bedsheets and bedding

REFERENCE

PIECE OF STEEL URETHRA

DESCRIPTION
A rare form of intussusception, deficiency of urothelium caused by a fixed, open, and nonfunctioning urethra. This is usually the result of prior pelvic surgery, irradiation, or longstanding indwelling catheter drainage. Patients typically have a high bladder neck on cystoscopic exam and severe urinary incontinence.

TREATMENT
- Mid-urethral sling
- Urethroplasty
- Artificial urinary sphincter

REFERENCE

PI-RADS PROSTATE MRI SCORING SYSTEM

DESCRIPTION
The European Society of Urogenital Radiology (ESUR) developed a scoring system to present multi-parametric prostate MRI data in a simple but meaningful way in the diagnosis of prostate cancer. The system is similar to that used by breast radiologists (BI-RADS) for breast mammography, breast ultrasound, and MRI. Multiple parameters for each lesion are scored on a 5-point scale and the overall score predicts the chance of the lesion being a clinically significant cancer.

- Score 1: Clinically significant disease is highly unlikely to be present.
- Score 2: Clinically significant cancer is unlikely to be present.
- Score 3: Clinically significant cancer is equivocal.
- Score 4: Clinically significant cancer is likely to be present.
- Score 5: Clinically significant cancer is highly likely to be present.

PLAP (PLACENTAL ALKALINE PHOSPHATASE)
DESCRIPTION PLAP is a fetal isoenzyme that has a different source than the adult alkaline phosphatase. It is 1 of many tumor markers used for the diagnosis, staging, and monitoring of treatment response in patients with GC, and it may be useful as a prognostic index. Although the individual sensitivity of PLAP is low, when combined with gamma-glutamyl transpeptidase, simultaneous determinations have shown elevations in 1% or both in 90% of patients with active disease.
REFERENCE

PLASMACYTOMA UROTHELIAL CARCINOMA
DESCRIPTION Plasma cytomai urothelial carcinoma (PUC) is a rare and recently described histologic variant of urothelial cancer (TCC). Tumor tissue is predominantly manifested by infiltrating tumor cells, with characteristics of plasmacytoid morphology. Cells appear medium-sized and desmoplastic with abundant eosinophilic cytoplasm, small hyperchromatic nuclei, and frequent mitotic features. In addition, immunohistochemical staining play an important role in the diagnosis of PUC. The most common presenting symptom is hematuria, generally accompanied by, lightly hematuria usually of low output. However, early diagnosis cannot be made due to the absence of hematuria until the later stages of disease. Due to the highly metastatic potential and poor prognosis of this variant of urothelial carcinoma (TCC), treatment options include deep TURBT for initial diagnosis, followed by radical cystectomy with adjuvant therapy.
REFERENCE

PLASMACYTOMA, BLADDER
DESCRIPTION This tumor is characterized by a monotonous proliferation of plasma cells at variable stages of differentiation, with predominance of the immature variety. 5 cases have been reported in the literature, with a mean age of 54 yr, none of which had multiple myeloma at the time of diagnosis. Local suprapubic recurrences and regional lymph node metastasis may occur. Survival up to 12 yr after diagnosis has been reported.
TREATMENT
• Subtotal cystectomy
• Radiation and chemotherapy
REFERENCE

PLASMACYTOMA, TESTICULAR
DESCRIPTION Neoplastic collections of plasma cells occurring in the testes. Plasmaocytes are most commonly found in the head and neck region. These are very rare tumors, with an incidence of 1 in 1,000 testicular tumors. They are most commonly associated with a previous or concurrent diagnosis of multiple myeloma and are generally not believed to occur as primary tumors. Presentation is a painless, tender testicular mass. Treatment is radical orchectomy and monitoring or management of multiple myeloma.
REFERENCE

PLASMACYTOMA, BLADDER CANCER
DESCRIPTION Ploidcy is the chromosomal content of cells, which can be measured using flow cytometry. Ploidcy analysis, when considered as an independent variable, is a fair predictor of clinical outcome. Tumor stage and grade are considered to be the most important predictors of survival. Although ploidcy may be more significant in predicting survival than grade, the addition of ploidy to the known stage and grade of a bladder tumor usually does not drastically alter the clinical management of a patient.
REFERENCE

PLOIDY ANALYSIS, BLADDER CANCER
DESCRIPTION Ploidcy is a variation in the number of chromosomes in a cell. Aneuploidcy is a variation in the number of chromosomes in a cell that is other than a single multiple of the number of chromosomes. In a prostate specimen, flow cytometry is used to measure the DNA content of the cells. DNA ploidy in addition to the histologic grading may improve the ability to predict the pathologic stage and ultimately the prognosis of any given lesion. The frequency of aneuploidy increases with advancing tumor stage. Inherent problems with ploidcy analysis include heterogeneity of DNA cell sampling, as well as whether it will change clinical management.

PNEUMOSCROTUM
DESCRIPTION Pneumoscrotum, the presence of air within the scrotum, can result from both pathologic and iatrogenic etiologies. This term includes both scrotal emphysema, which is subcutaneous air palpated as crepitis, and pneumatocele, where air is present within the tunica vaginalis and not directly palpable. Air may come from extraperitoneal (lytic pneumatocele, intraperitoneal (perforated viscus), or local self-producing (microorganisms) sources. The underlying cause must be recognized early, as certain conditions may be life-threatening (pneumothorax, fourner gangrene, intestinal perforation) and treatment of the underlying cause allows the pneumoscorpoum to resolve. Today, pneumoscorpoum is sometimes seen after laparoscopic or robotic peritoneal or extraperitoneal procedures and resolves spontaneously.

POLYARTERITIS NODOSA (PAN), UROLGIC CONSIDERATIONS

PNEUMOSCROTUM
DESCRIPTION Air may affect many organ systems. It usually presents with a systemic illness characterized by malaise, weight loss, myalgia, arthralgia and signs of end-organ damage. PAN is not well understood, but is believed to be caused by the deposition of immune complexes on the walls of primarily medium-sized arteries, causing inflammatory changes in these walls. This may lead to thickening and neointimal changes, causing acute renal hemorhage and often leading to chronic renal failure. When left untreated, the 5-yr survival rate of PAN is 13% with some renal features being associated with poor prognosis: Renal insufficiency (serum creatinine > 1.58 mg/dL and proteinuria > 1 g/dL).

When left untreated, the 5-yr survival rate of PAN is 13% with some renal features being associated with poor prognosis: Renal insufficiency (serum creatinine > 1.58 mg/dL and proteinuria > 1 g/dL). Corticosteroids and azathioprine are used in the treatment of PAN. The majority of patients with PAN have renal involvement. Flank pain is sometimes present and splenomegaly (ischemic changes, and renal atery vasculitis can cause renal failure) (a small percentage of patients may require dialysis), hypertension, or both. Infrequently patients may develop pain over the testicular or ovarian area with testicular infarction reported. Renal spontaneous renal hemorrhage is also reported. Steroids with or without cyclophosphamide is the standard treatment.

REFERENCES
POLYEMBRYOMA

DESCRIPTION A mixed germ cell tumor (SGT) of the testis, containing embryonal carcinoma and yolk sac tumor. Histologic analysis reveals a distinctive, well-differentiated pattern of endodermal bodies in a mesenchymal stroma, which resembles extraterritorial mesothelioma. Due to the yolk sac component there may be substantial alpha fetoprotein (AFP) elevation. Treatment mirrors that for OCT.

POLYOMA VIRUS (BK, JC), UROLOGIC CONSIDERATIONS

DESCRIPTION The polyoma viruses may cause transplant renal nephropathy, unilateral obstruction or stricture, and hemorrhagic cysts. BK virus may cause transplant renal nephropathy in up to 6% of transplant recipients, and may cause unilateral obstruction secondary to fibrosis. It is also thought to be the causative agent in the majority of patients with hemorrhagic cysts following immunosuppression for bone marrow or solid organ transplantation.BK virus causes clinical disease of the genitourinary tract, due in part to its tropism for genitourinary epithelium. The JC virus causes a similar disease pattern but is less common. BK nephropathy occurs in up to 10% of kidney transplant recipients and causes graft failure in as many as 50% of individuals affected. BK and JC viruses can be diagnosed with PCR of the urine or blood. Urine cytology may demonstrate the so-called “decoy cells.” Most renal transplant programs employ posttransplant screening programs. Decreasing immunosuppressive medications is essential. Additional therapies include agents such as ciprofloxin and ivig. (See also Section I: “Immunocompromised Patients, Urologic Considerations” and Section II: “BK Virus, Urologic Considerations.”)

POLYORCHIDISM

DESCRIPTION This is a very rare condition characterized by multiple (>2) testicles. It may be the result of transverse division of the urogenital ridge. The majority of cases are asymptomatic and associated with inguinal hernia, torsion, or cryptorchidism. It is most often discovered as an asymptomatic swelling in the scrotum; the supernumerary testes usually occur with its own separate epididymis and vas deferens. If a testicular tumor can be ruled out using US or MRI, and if surveillance indicates no other associated disorders, surgical exploration is not necessary.

TREATMENT Surgery, exploration, biopsy, if indicated

A test that evaluates the interaction between sperm and cervical mucus. It determines the adequacy of sperm and the receptivity of cervical mucus. Testing consists of retrieving specimens from the posterior vaginal fornix, excervix, and endocervical canal —6–8 hr after intercourse. The test should be performed close to the time of ovulation, and couples are asked to abstain from sex for 48 hr prior to the test. These specimens are examined to determine the number of motile sperm, with 10 sperm/field considered adequate and excluding the cervical mucus as cause of infertility. When these test results are poor, the specimen may be repeated on another occasion, 1–3 hr after coitus.

SYNONYM
Sims–Frunieri Test

REFERENCE

POSTTRANSPLANT LYMPHOPROLIFERATIVE DISORDER

DESCRIPTION
Posttransplant lymphoproliferative disorder (PTLD) is a heterogeneous disease that may occur in recipients of solid organ transplants and hematopoietic stem cell transplants. The risk of lymphoma is increased 20–100% compared with the general population. Epstein–Barr virus infection at the time of transplantation appears to be a significant risk factor. Based on morphologic, immunophenotypic, and molecular criteria, PTLD is classified into four pathologic categories: Early lesions, polymorphic, monomorphic, and classical Hodgkin lymphoma. A mainstay of therapy is reduction of immune suppression but often single agent rituximab or even combination chemotherapy is needed.

REFERENCE

POSTVOD DRIBBLING

DESCRIPTION
Urine that leaks out or the urethra at the end of micturition. It may be caused by bladder outlet obstruction, an urethral diverticulum, or vesicovaginal reflux of urine. Recent data suggests it may also be seen in the median lobe hypertrophy.

REFERENCE

POTASSIUM SENSITIVITY TESTING

DESCRIPTION

REFERENCE
Precocious puberty

DESCRIPTION

Precocious puberty is sexual development at an earlier age than expected. In general, signs of secondary sexual development in boys <9 and in girls <10 are not precocious. In white girls <7 or in black girls <6 is precocious. Common causes include medications (illegitimate estrogens or testosterone), idiopathic causes, pituitary and CNS tumors (harmatogenous), CSH, adrenal tumors, ovarian cysts and tumors, McCune-Albright syndrome, Leydig cell tumors, HCG-secreting GCT, neuroblastoma, or pseudopseudohyponadism.

REFERENCE

PREGNANCY, BACTERIURIA, PYURIA, AND URINARY TRACT INFECTION

DESCRIPTION

Pregnant women with asymptomatic bacteriuria have a higher likelihood of developing a UTI and should be treated to reduce the incidence of pyelonephritis, sepsis, and fetal complications (low birth weight, prematurity, death). Pyuria in the presence of bacteriuria indicates UTI. Pyuria in the absence of bacteriuria should raise suspicion for nephrolithiasis, TB, or less commonly, malignancy of the urinary tract. Pericystitis and cholelithiasis (FDA category B) are generally agreed to be safe in pregnancy. Drugs with high protein binding (eg, Ceftazidime) may be inappropriate the day before birth as a result of the placental barrier. Because of the likelihood of bilateral displacement and herniation risk, fluoropyrimidines should be avoided in pregnancy. (See also Section II: “Bacteriuria and Pyuria” and “Pregnancy, Obstetrics.”)

TREATMENT

The following regimens have been reported in treating cystitis in pregnancy modified based on urine culture results:

- Nitrofurantoin 100 mg orally every 12 hr for 5 days
- Ceftriaxone: 1 g every 24 hr
- Cefazolin: 1 g orally every 12 hr for 3–7 days
- Fosfuromycin: 3 g orally as a single dose

The following regimens have been reported in treating pyelonephritis in pregnancy modified based on urine culture results:

- Nitrofurantoin 100 mg orally every 12 hr for 5 days
- Ceftriaxone: 1 g every 24 hr
- Cefazolin: 1 g orally every 12 hr for 3–7 days
- Fosfuromycin: 3 g orally as a single dose

The following regimens are reported for mild to moderate pyelonephritis in pregnancy:

- Cephalexin: 500 mg PO every 8 hr
- Amoxicillin: 500 mg PO every 8 hr
- Cefprozil: 250 mg PO every 12 hr

The following regimens are reported for severe pyelonephritis with intra-abdominal and/or incomplete urinary drainage:

- Trimethoprim-sulfamethoxazole: 1.975 g every 6 hr
- Meropenem: 500 mg every 8 hr
- Daptomycin: 600 mg every 8 hr
- Vancomycin: 1 g every 8 hr

The following regimens are reported for severe pyelonephritis with intra-abdominal and/or incomplete urinary drainage:

- Trimethoprim-sulfamethoxazole: 1.975 g every 6 hr
- Meropenem: 500 mg every 8 hr
- Daptomycin: 600 mg every 8 hr
- Vancomycin: 1 g every 8 hr

REFERENCES

PREGNANCY, URINARY DIVERSION

DESCRIPTION Pressure after urinary diversion has not been well studied, and only 210 cases have been reported in the literature thus far. Patients have more difficulty getting pregnant because of their inherent underlying disease process, metabolic changes from urinary diversion, and because of the fixed position of the uterus from prior surgery. These patients have special ureteral considerations from decreased perfusion of the bowel segment from compression of the conduit or neobladder by the uterus, malabsorption of food due to use of the terminal ileum, stoma prolapse from increased intra-abdominal pressure, sternal stenosis from impaired blood flow, difficulty catheterizing continent pouches from stretching of the urethra, and an increased risk of UTI from the presence of bacteria. Unique postpartum issues include adhesions of the small intestine that may complicate cesarean section, increased residual urine volumes from stretching of conduits or neobladders, and an increased risk of pelvic organ prolapse.

PREGNANCY, URINARY TRACT OBSTRUCTION

DESCRIPTION Urinary tract obstruction during pregnancy most commonly occurs from a urinary stone or extrinsic compression from the gravid uterus. Patients will commonly present with flank pain, UI, magnetic resonance urography, or low-dose CT may be used to evaluate for a ureteral stone and evidence of obstruction. Hydronephrosis is a common finding in pregnancy and may be found in 15%, 20%, and 50% of patients in their 1st, 2nd, and 3rd trimesters, respectively. It is more common on the right side, and is commonly thought to occur from progesterone-mediated ureteral dilatation and extrinsic compression. See also Section II: "Pregnancy, Urothology" and Section III: "Pregnancy, Radiologic Considerations."

TREATMENT
- Initially, conservative with IV hydration and analgesic therapy.
- Patients who fail may require stent or nephrostomy tube placement. Stones can rapidly erode due to increased urinary calcium excretion and should be changed in a timely fashion.
- Lithotripsy and laser lithotripsy.

PREGNANCY, UROLOGIC MALIGNANCY

DESCRIPTION Urologic malignancies are rare in pregnancy but often misdiagnosed due to overlapping signs and symptoms with pre eclampsia and eclampsia. The most common tumor is RCC, which may present as flank pain, hematuria, and a palpable mass. It is often identified incidentally on imaging. Pheochromocytomas have been reported to occur in 1 of 50,000 term pregnancies. They present with severe hypertension, headaches, palpitations, vomiting, visual changes, and without proteinuria unlike preeclampsia. Adrenal adenomas may present with Cushing syndrome. Renal angiomyolipomas may present with flank pain, hematuria, and retropitoneal hematuria, although it is sometimes incidentally diagnosed on imaging. Urolithiasis of the upper or lower tracts is rare and presents with hematuria. If urine analysis reveals hematuria and the culture is negative, cystoscopy, and upper tract imaging are warranted.

TREATMENT
- Removal of pheochromocytomas is controversial, but medical therapy may be used until the 3rd trimester or delivery of the fetus.
- The size and type of tumor should dictate management for RCC, and laparoscopic nephrectomy has been shown to be safe in pregnant women.
- Angiomyolipoma (AML) with hematuria may be managed with embolization or partial or total nephrectomy.
- Urolithal cancer should be managed endoscopically given its propensity for aggressive growth and lymphatic invasion. Mitomycin should be avoided, and only 1 case report exists of using RCC.

PREGNANCY, UROLGIC MEDICATIONS

DESCRIPTION Medications in pregnancy have not been well studied or documented. Urologic issues include antibiotics for UTI and anesthesia for surgical procedures. Macrobid is a safe, well-tolerated antibiotic classified as a category B (no evidence of harm to human fetus) drug by the FDA. There is a recommendation against using this in the 3rd trimester because of the risk of hemolytic anemia in patients with G6PD deficiency. Fluoroquinolones are considered category D medications, but multiple studies have failed to demonstrate any evidence of harm. Penicillins are category B drugs, and often the medication of choice in pregnancy. General anesthesia may carry a slightly higher risk of maternal infections and premature labor; this effect is directly related to the complexity and length of the procedure but the overall increased risk is thought to be minimal. See also Section II: "Pregnancy, Urothology, Fyuna, and UI."

PREHN SIGN

DESCRIPTION Prehn sign is a clinical test used to aid in distinguishing epididymitis from testicular torsion although it is not always reliable. The physical lifting of the testicle is said to relieve the pain of epididymitis (positive Prehn sign), but does not relieve the pain of testicular torsion (negative Prehn sign). It is important to note that Prehn sign is not always reliable and Doppler ultrasonography is a valuable tool in confirming the diagnosis.

PRENTISS MANEUVER

DESCRIPTION Additional curl in an orchiopexy operation can be gained by fixing the inguinal floor and lifting the inferior epididymal vessels. The internal ring and transversalis fascia are then closed lateral to the cord.

PREPUTIAL STONES

DESCRIPTION Preputial stones (preputial calculus) are rare occurrences, generally found in adults and associated with poor penile hygiene, low socioeconomic status, and phimosis. Factors in preputial stone formation include obstruction, stress, foreign body, nodule formation, and infection. Removal of stone and elimination of the predisposing condition is the treatment.

PRESSURE-FLOW STUDIES

DESCRIPTION The simultaneous measurement of bladder pressure and urethral flow through the entire voiding cycle. Performed as part of urodynamic study, these studies improve on some of the limitations of uniflowmetry alone. Measurements for this study can include the variables that affect the study. Intravesical pressure, rectal pressure, intrarenal pressure, urothelial electromyogram, and urine flow rates. A small catheter is placed to fill the bladder and measure the flow. All variables are plotted and recorded simultaneously to compare the various readings during various points in the micturition study.

PREGNANCY, STUTTERING (INTERMITTENT PRIAPISM)

PRIMITIVE NEUROECTODERMAL TUMORS (PNET) (EXTRASKELETAL EWING SARCOMA)

TREATMENT
- Hormonal therapy (bupropion, busulamide, bicalutamide)
- Self-injection therapy with phenylephrine

REFERENCE

PRIMITIVE NEUROECTODERMAL TUMORS (PNET) (EXTRASKELETAL EWING SARCOMA)

DESCRIPTION
Primitive neuroectodermal tumors are part of the Ewing family of tumors (EFT) that include Ewing’s sarcoma of the bone. Peripheral PNETs are a very aggressive neoplasm that predominantly affects children and adolescents. Renal PNET is the most reported PNET of the genitourinary tract, however bladder, prostate, ureter, and seminal cord PNETs have also been reported. PNETs are often diagnosed as metastatic disease (20–50%) and the outcome is often poor, with a 5-yr survival rate of 6%.5

TREATMENT
Multimodal therapy including surgical resection, chemotherapy, and radiation.

REFERENCE

PRINCETON III CONSENSUS RECOMMENDATIONS: ERECTILE DYSFUNCTION (ED) AND CARDIOVASCULAR DISEASE

DESCRIPTION
The recommendations of the 3rd Princeton Consensus Conference focus on (1) evaluation and management of cardiovascular risk in men with and/or no known CV disease, (2) reevaluation and modification of the 2nd conference recommendation for evaluation of cardiac risk associated with sexual activity in men with known CV disease, and (3) the role of testosterone replacement therapy (TRT) in ED and CV disease management (Image Q).

REFERENCE

PROLACTIN, SERUM LEVEL

DESCRIPTION
Elevated prolactin levels (>50 ng/mL) suggest a prolactinoma. Renal failure, stress, medications, and hypothyroidism have serum prolactin value <50 ng/mL.

TREATMENT
- Cabergoline
- Bromocriptine
- Surgical resection

REFERENCE

PROLAPSE, STAGING SYSTEMS

DESCRIPTION
Since the early 1960s multiple practitioners including Porge, Baden, Walker, and Beecham have attempted to standardize pelvic organ prolapse. Then in 1996 the American Urogynecologic Society, the Society of Gynecologic Surgeons, and the ICS adopted the Pelvic Organ Prolapse Quantitation (POP-Q) exam. The POP-Q exam, in which 9 specific points of measurement are obtained in relation to the hymenal ring, has been demonstrated to be learned easily and performed quickly with highly reproducible exam findings. The most widely used classification systems used today are the Baden-Walker and POP-Q systems. (See also Section II: “Cystocele Grading: Baden-Walker. Pelvic Organ Prolapse Quantification (POP-Q).”

REFERENCE

PROPRANOTHINE STIMULATION TEST

DESCRIPTION
This test is used when involuntary detrusor contractions are demonstrated during cystometry to predict the outcome of pharmacologic treatment with anticholinergic. Propranolol bromide is an anticholinergic with side effects that include dry mouth and blurred vision. Since involuntary detrusor contractions have been confirmed, 15 mg of propranolol bromide are administered parenterally. Once effects of the drug are noted, cystometry is repeated. A positive response is defined as the complete abolition of involuntary detrusor contractions, or a 20% increase in the bladder volume at which they occur. If the parenteral dosage is effective, a tolerable clinical response to the orally administered dose can be expected in most patients.

REFERENCE

PROPHYLACTIC ANTIBIOTICS, AUA GUIDELINES

DESCRIPTION
Recommendations include limiting antibiotic prophylaxis to a maximum of 24 hr, no prophylaxis solely to prevent infectious endocarditis, and defining characteristics for patients at higher risk. These characteristics include advanced age, prostatic anomalies of the urethral tract, poor nutritional status, smoking, chronic corticosteroid use, immunodeficiency, external catheters, colored endogenous/exogenous material, distant cancer infection, and prolonged hospitalization. Recommendations for specific procedures and agents are found in Section VII. “Reference Tables: Antibiotic Prophylaxis: AUA guidelines.”

REFERENCE

PROSTASCINT SCAN

DESCRIPTION
A nuclear medicine imaging study designed to localize prostate cancer cells using a radiolabeled monoclonal antibody to PSMA (prostate-specific membrane antigen) called indium 111 capromab pendetide. Patients are injected, and single photon emission computed tomography is performed immediately after scan and 4–5 days later. This allows for washout of antibody from the blood and bowel. The test was initially designed to identify extraprostatic disease, and current applications include identifying the location of cancer recurrence following definitive therapy for prostate cancer. It has traditionally suffered from poor specificity and interobserver reliability and issues concerning uptake of mid abdominal lymph nodes. Recent data suggest that there may be renewed interest in integrating the Prostascint scan in clinical decision making for deciding between local vs. systemic salvage therapy for PSA recurrence following definitive management of prostate cancer (Image H).

REFERENCE

PROSTATE CANCER SCREENING GUIDELINES

DESCRIPTION
Screening asymptomatic men for prostate cancer is controversial. Concerns about over diagnosis and overtreatment of clinically important cancers are part of this reason. Many professional organizations have developed guidelines concerning prostate cancer screening that are summarized in the table. (See also Section II: “AUA, General Considerations” and Section VII: Reference Tables: Prostate Cancer Screening Guidelines.)

REFERENCES

Several 1st degree relatives diagnosed with PCa at age 50-70 with normal DRE & PSA

American Cancer Society (ACS) 2010

American College of Physicians (2013)

American Urological Association (2013)

National Comprehensive Cancer Network (NCCN)2014

USPSTF (2012)

a African-American or have a 1st degree relative diagnosed with PCA ≤ 65 yr of age

b Several 1st degree relatives diagnosed with PCA ≤ 50 yr of age

DESCRIPTION

As screening for prostate cancer can result in the diagnosis of prostate cancer in many men who are not likely to suffer any consequences or die from the disease. This often results in over-treatment of many men with prostate cancer. Deferred therapy for those with prostate cancer generally involves 2 different approaches although the terms are often used interchangeably. They are not completely identical:

- Active surveillance is a strategy aiming to individualize the management of early prostate cancer by selecting only those men with significant cancers for active therapy. This involves actively monitoring the course of prostate cancer with the intent of intervention with definitive local therapy (eg, radiation therapy, RP) if cancer progression is documented.

- Watchful waiting uses less aggressive follow-up until the patient develops symptomatic disease progression, at which time he is often placed on hormonal treatment. (See also Prostate Cancer, General and “Prostate Cancer, Very Low Risk and Active Surveillance.” Section 8: “Surgical Options.”)

PROSTATE CANCER, BASAL CELL CARCINOMA

DESCRIPTION

A very rare variant of prostate cancer comprising ≤ 0.1% of malignant tumors. Lesions exist in 2 distinct forms, adenoid cystic carcinoma (ACC), and basal cell carcinoma (BCC), that occur clinically separate or as mixed tumors with 1 dominant pattern. Immunohistochemical analysis reveals strongly positive results for both 34 βE12 and p63. OncotypeDX is a more reliable form of prostate cancer current evidence supports the potential for local recurrence and metastasis and therefore suggests radical surgery with life-long follow-up as 1st-line management.

PROSTATE CANCER, CIRCULATING TUMOR CELLS (CTC’S)

DESCRIPTION

Circulating tumor cells (CTC’S) can be detected using molecular techniques such as RT-PCR. An identification assay for actual circulating cells (CellSearch) is commercially available for use in patients with hormone-refractory prostate cancer. In patients with advanced prostate cancer, men with ≥5 CTC’s per 7.5 mL blood prior to chemotherapy had a significantly shorter median survival (10 vs. 21 mo in those with <5 CTC’s). The role of the CTC assay continues to evolve in the management of prostate cancer. It appears to be only valid at present for men with advanced, castrate resistant prostate cancer disease and is not used for earlier stages of disease. (See also Section 8: “PSA, BT-PSA.”

REFERENCES

PROSTATE CANCER, DUCTAL ADENOCARCINOMA

DESCRIPTION

These terms have been replaced by ductal adenocarcinoma of the prostate. It accounts for 1-2% of all prostate adenocarcinomas. Due to its appearance, ductal adenocarcinoma was previously thought to arise from mesothelial remnants and possess unique clinical features related to its origin. While further analyses have shown that these tumors do in fact arise from prostatic tissue. The disease originates from perineural ductal prostate ducts and may grow into an exophytic seminal vesicle around the verumontanum. A mixture of cribriform and papillary structures is seen on microscopy, resembling endometrial adenocarcinoma of the uterus and hence the earlier descriptive terms. Histologically, these tumors are composed of tall columnar cells with clear to eosinophilic cytoplasm and large nuclei. The cells form glands with scant intervening stroma. Prostatic ductal adenocarcinoma cells express PSA. Prostate adenocarcinoma is also present in 17% of cases. Early presentation is hematuria, irritative and obstructive symptoms and it tends to occur in older men (>60-80 yr). Serum PSA levels and DRE at the time of diagnosis tend to underestimate disease.

Cytoscopically it may appear multiple polyloid friable protrusion from near the notch of the prostate. Often these are not as easily endoscopic findings. Sources are conflicting concerning the clinical presentation of ductal adenocarcinoma. Due to the early symptom presentation most are organ confined and others more likely to present with advanced stage cancer. The behavior has been compared to behave similar to adenocarcinoma (4-4-4) prostate adenocarcinoma.

SYNONYMS

- Ductal carcinoma of the prostate
- Endometrioid carcinoma, prostate
- Endometrial carcinoma of the prostate
- Papillary adenocarcinoma of the prostate

TREATMENT

Similar to high-grade urothelial adenocarcinomas of prostate. Most of the literature has been managed by local prostatectomy. Ductal carcinoma of the prostate tends to be hormone sensitive and advanced disease is initially responsive to androgen deprivation. The overall mortality was significantly worse in men with ductal adenocarcinoma, almost 3-fold higher rate of death, as compared to prostate adenocarcinoma.

757
PROSTATE CANCER, FAMILIAL

DESCRIPTION
The risk of prostate cancer is directly dependent upon the number of affected 1st-degree relatives, the age of the relative when diagnosed, and whether the relative is a father or brother. Risk is also associated with a family history of breast cancer.

REFERENCES

PROSTATE CANCER, LEIOMYSARCOMA, AND OTHER UNCOMMON SARCOMAS

DESCRIPTION
Leiomyosarcoma of the prostate is extremely rare and a highly aggressive neoplasm, accounting for <0.1% of primary prostate malignancies. It is the most common primary prostatic sarcoma of the prostate in adults, and comprises 38–52% of adult prostatic sarcomas. Rhadomyosarcoma is most common in pediatric patients and can be seen in adults. Other less common prostatic sarcomas include MPNST and prostatic chondromalacia. Presentation can include urinary obstruction frequency, urgency, hematuria, pelvic pain, rectal pain, constipation, burning on ejaculation, and frequency, urgency, hematuria, perineal and/or rectal pain, clumping.

REFERENCES

PROSTATE CANCER, PREVENTION (CHEMOPREVENTION)

DESCRIPTION
Numerous medications and nutraceuticals, including selenium, statins, and green tea, have been evaluated for the prevention of prostate cancer, with the most notable being the 5α-reductase inhibitors (5 ARIs) finasteride and dutasteride. The Prostate Cancer Prevention Trial (PCPT) using finasteride demonstrated an almost 25% reduction in the incidence of prostate cancer but a slightly increased incidence of higher Gleason score prostate cancer. Some have hypothesized this may be due to selection inhibition of low-grade cancers along with a smaller prostate size resulting in less sampling error and better detection of higher grade cancers already present. This is supported by whole-mount correlation from RP specimens. The Reduction of Prostate Cancer (REDUCE) trial using dutasteride (a dual 5α-reductase inhibitor) reported a 23% reduction in prostate cancer in high-risk men with a slight increase in high-grade cancers. The large SELECT trial using selenium and vitamin E was stopped prematurely because it did not appear that either agent alone or in combination reduced the risk of prostate cancer. In 2011, updated trial data showed that the men taking vitamin E had a 17% increased risk of prostate cancer compared to men taking placebo. Trial sponsors recommended that men avoid supplementation with these agents.

PROSTATE CANCER, RISK STRATIFICATION (D’AMICO CLASSIFICATION)

DESCRIPTION

One challenge presented by prostate cancer is choosing the appropriate therapy based on the risk of disease progression. It is often useful to assign a relative risk to an individual. These risk groups were established from literature and based on known prognostic factors: PSA level, biopsy Gleason score, and 1993 AJCC staging. A typical system, commonly referred to as the D’Amico classification, is described here. Note that this is risk of PSA progression posttherapy and not overall or disease-specific survival:

- Low risk: Stages T1c and T2a, PSA level of ≤10 ng/mL, and biopsy Gleason score of ≤6 (25% PSA progression at 5 yr posttherapy)
- Intermediate risk: PSA levels of 10–20 ng/mL, biopsy Gleason score of 7, or AJCC clinical stage T2b (25–50% PSA progression at 5 yr posttherapy)
- High risk: T2c disease or a PSA level >20 ng/mL or a Biopsy Gleason score of ≥8–10 (50–100% PSA progression at 5 yr posttherapy)

REFERENCE

PROSTATE CANCER, SMALL CELL (NEUROENDOCRINE)

DESCRIPTION

A rare subtype of prostate malignancy that has a rapid fatal course. Considered to be a variant of Gleason's adenocarcinoma of the prostate, it is identical to small cell carcinoma of the lung and has neuroendocrine (small cell, oat cell) differentiation. In 50% of the cases, the tumors are mixed small cell carcinoma with adenocarcinoma. Histopathologically, prostate SCCs of the prostate are part of a spectrum of anaplastic tumors of the prostate and are similar to SCCs of the lung. Neuroendocrine cells are identified by special staining (ie, neuro-specific enolase [NSE] or other markers). It should be noted that the normal prostate does have some neuroendocrine positivity, but it is limited and can only be detected by staining. About 10% of adenocarcinomas of the prostate can have Paneth-like cells (large eosinophilic cells) that are neuroendocrine, and it is recognized that adenocarcinoma of the prostate that is not classified as neuroendocrine can have some pathy cells that stain as neuroendocrine cells. Large numbers of these cells in a prostate sample should prompt a neuroendocrine staining workup of the sample. Tumors can exhibit a spectrum of differentiation, with a carcinoid-like pattern (low-grade neuroendocrine carcinoma) to the small cell undifferentiated type (oat cell), the highest grade of neuroendocrine tumor. Immunohistochemically, these cells can stain for serotonin, calcitonin, ACTH, HCG, and other markers. Most of these small cell tumors do not produce detectable levels of hormones but sometimes can produce detectable levels in the serum. They may also express and stain for PSA and acid phosphatase, but pure small cell carcinoma usually does not stain for PSA. The clinical behavior of small cell prostate carcinoma is characterized by extensive local disease, visceral disease, and low PSA levels despite large metabolic burden. At diagnosis, 70% of patients have metastatic disease, and visceral metastases are common (ie, liver). The average survival is <1 yr. Androgen receptor-positive tumors have a worse prognosis than do tumors that do not express the receptor (median survival 10 mo vs. 30 mo). Diagnosis is made by TRUS biopsy, symptoms associated with metastasis, and elevated LFTs and CEA.

SYNONYMS

- Small cell anaplastic carcinoma of the prostate (SCCP)
- Oat cell carcinoma of the prostate
- Neuroendocrine prostate cancer
- Carcinoid of the prostate

TREATMENT

- These tumors respond poorly to androgen ablation, but this should be attempted.
- Surgery and/or radiation therapy may provide local control.
- Chemotherapy with agents such as VP-16 and cisplatin have some activity.

REFERENCE

PROSTATE CANCER, SQUAMOUS AND ADENOSQUAMOUS

DESCRIPTION

A rare lesion that can arise in patients infected with Schistosoma haematobium. It can be confused with more common conditions, such as squamous metaplasia of the prostate due to infection, radiation, and hormonal therapy. Pure primary SCC of the prostate does not respond to estrogen therapy, and it does not develop elevated serum PSA or NET levels with metastatic disease. Bone metastases are osteolytic instead of osteoblastic. Median survival is about 14 mo.

REFERENCE

PROSTATE HEALTH INDEX (PHI) AND [–2] proPSA

PHI

The Prostate Health Index (PHI) is a mathematical combination of total PSA (tPSA), free PSA (fPSA) and [–2] proPSA (Ostenson et al. 2013). The mathematical equation is: PHI = (tPSA) × (fPSA). The PHI has been shown to have a higher PSA predictivity value than both total PSA and free PSA. The measurement of %[–2] proPSA improves the accuracy of prostate cancer detection in comparison with PSA or fPSA, particularly in the group of prostate cancer patients between 3 μg/L and 10 μg/L. The PHI may also be able to reduce the number of unnecessary biopsies, maintaining a high cancer detection rate. Published results also showed that %–2 proPSA and PHI are related to the aggressiveness of the tumor.

REFERENCES

PROSTATE URETHRAL ANGLE

DESCRIPTION
The prostatic urethral angle is the angle formed between the prostate from the base to the apex, making an anterior angle of ≈35° at the proximal verumontanum. In men with prostate hypertrophy, this angle tends to be >75°. However, men without hypertrophy have a more uniform prostatic urethral angle. A high bladder neck in men without prostatic enlargement, and in preliminary clinical studies, the PUA was inversely associated with the urinary flow rate.

REFERENCE

PROSTATE, BASAL CELL HYPERPLASIA

DESCRIPTION
Basal cell hyperplasia is important in that it is commonly associated with BPH and may sometimes be mistaken for prostate cancer. The prostate epithelium consists of 3 major cell types: epithelial, basal, and neuroendocrine cells. The basal cells are small and round with a scant cytoplasm and dark nuclei. These cells are less differentiated and almost devoid of secretory products; they are located between the secretory cells and rest on the basement membrane. Basal cells are negative for PSA and PAP.

Typical basal cell hyperplasia consists of a proliferation of basal cells ≥2 cell layers thick at the periphery of prostatic glands and acini. Basal cell proliferation in the prostatic gland is highlighted from focal basal cell hyperplasia in the setting of nodular hyperplasia to a florid adenoid basal cell tumor. Many confusing names have been used in the literature. Totallization of prostate, embolial hyperplasia, basal cell tumor, basal cell adenoma, BC adenoid carcinoma. The differential diagnosis includes transitional cell hyperplasia, squamous metaplasia, urothelial carcinoma (TCC) of the prostate, and adenocarcinoma of prostate.

REFERENCE

PROSTATE, BENIGN ENLARGEMENT (BPE)

DESCRIPTION
Benign prostatic enlargement is used when there is gland enlargement and is usually a prescriptive diagnosis based on the size of the prostate. This term differs from BPH which is reserved for the histological pattern it describes. A patient may have LUTS with or without BPE. (See also Section I: “Bladder Outlet Obstruction [BDO].” Prostate, Benign Obstruction [BPO]) and “Section II: “Prostate, Benign Obstruction [BPH].”"

REFERENCE

PROSTATE, BENIGN OBSTRUCTION (BENIGN PROSTATIC OBSTRUCTION [BPO])

DESCRIPTION
BPO is used when obstruction has been proven by pressure-flow studies, or is highly suspected from flow rates and if the gland is enlarged. This is different from bladder outlet obstruction, the generic term for all forms of obstruction to the bladder outlet (e.g., urethral stricture including BPO). (See also Section I: “Bladder Outlet Obstruction (BDO).” Prostate, Benign Hypertrophy/Hyperplasia [BPH]."

REFERENCE

PROSTATE CALCULI

DESCRIPTION
Calculi are more common in older males and are rarely found in children. They usually occur in clusters and are associated with other disease processes. Often found in a dilated prostatic urethre. They are generally asymptomatic but may cause symptoms such as decreased urinary stream, prostatism, and lower back pain; they are a rare source of chronic bacterial prostatitis. Calculi may form secondary to calcification of the corpora amylacea and simple precipitation of prostatic secretions.

TREATMENT
 generally none
• Transurethral resection with laser lithotripsy as needed if markedly symptomatic

REFERENCE

PROSTATE, FEMALE

DESCRIPTION
A cored radiographic expression that refers to an impression at the base of the female bladder seen on cystography or ultrasonography. The impression resembles an enlarged prostate in the male and can be caused by urinary diverticulism, benign and malignant tumors of the anterior vaginal wall, urethral neoplasm, and repair of UI. Anatomically, the paraurethral glands and ducts are considered homologous to the male prostate and immunohistochemical studies demonstrate expression of PSA and prostate-specific acid phosphatase (PSAP) in these paraurethral glands and ducts.

REFERENCE

PROSTATE, HEMATURIA

DESCRIPTION
Hematuria attributed to bleeding from the prostate is a diagnosis of exclusion. Patients should have an appropriate workup according to the guidelines provided by the AUA. Older patients with larger, more vascular prostates are more susceptible and can be managed with finasteride, KIR/MIBI or transurethral resection if bleeding is refractory to medical therapy. Most often urothelial, Kawada can also be iatrogenic after prostate biopsy and endoscopic/evacuated resection or due to locally advanced prostate cancer late manifestation.

TREATMENT
• Prostatectomy (1st line therapy for troublesome benign prostatic hyperplasia bleeding)
• Intravesical alum, silver nitrate, and formalin
• Cold-line therapy
• Transurethral resection or vaporization of the prostate

REFERENCE

PROSTATE, INFARCTION

DESCRIPTION
The etiology of prostatic infarction is still unclear, although it has been linked to prostatic hyperplasia. Histologic findings include infarction of prostatic epithelium, with hemosiderin and neutrophils in the intervening stroma. Recent infarcts generally do not have squamous metaplasia, whereas older ones do. Typically, the infarction is multiple and located in the central and middle zones of the middle 1/3 of the prostate. Prostatic infarction may elevate PSA levels.

REFERENCE

PROSTATE, MASSAGE

DESCRIPTION
Repetitive prostate massage is not a new tool in the urologists’ armamentarium. It can be used to locate lower UTIs or as a therapeutic modality. Once the most popular therapeutic maneuver used to treat prostatitis, it was abandoned as primary therapy almost 30 yr ago. Based on experience reported outside North America and anecdotal experiences of some patients and their physicians, some believe it has a role in certain forms of prostatitis, such as chronic non-bacterial prostatitis or chronic pelvic pain syndrome (CPPS). The prostate is massaged from the lateral border to the medial aspect on each side, from base to apex. Firm pressure is necessary to express prostatic fluid into the urethra. A sterile container should be held by the patient or the measles to capture the expressed prostatic fluid. The test is commonly performed in acute bacterial prostatitis. (See also Section II: “Attentive Digital Rectal Exam (DRE).”"

REFERENCE
“Afferent Digital Rectal Exam (DRE):” Expressed Prostatic Secretions (EPS)."

Stamey Test (Three glass test, Four glass tests, Nilsson-Stamey Test):"
**PHOSPHATASE (PAP)**

**SYNONYMS**

Duct Syndrome [PMDS] and Prostatic Utricle

DESCRIPTION

A type of granulomatous prostatitis. Its activity is much greater in the prostate than in any other tissue. PAP is not prostate-specific, and can be found in other tissues. Historically, PAP was used as a serum marker for the staging and detection of prostatic cancer before the discovery of prostate-specific antigen (PSA). Although enzymatic activity of PAP is associated with advanced prostate cancer, other causes of an elevated PAP are possible, including liver, skeletal, and renal disease. PAP is the primary target for the prostate cancer immunotherapy sipuleucel-t.

**REFERENCES**

**PROSTATIC URETHRAL POLYPS**

DESCRIPTION

Urethral polyps are rare abnormalities in male children who present with hematuria or obstructive symptoms. Strangury (strenuous and painful urination) may be seen, with large lesions on a long stalk. The diagnosis is best confirmed by voiding cystourethrography. These polyps are nearly always in the prostatic fossa, although anterior urethral polyps have been reported. These are benign lesions and are not related to the polypidoma masses of sarcoma botryoids.

**TREATMENT**

Transurethral excision of the polyps

**REFERENCE**

**PROSTATIC URETHRAL ANOMALIES**

**DESCRIPTION**

The prostatic utricle is a small utilelne orifice found at the apex of the verumontanum. The utricle has been considered by most to be a remnant of the fused caudal ends of the mullerian ducts while others propose the origin is from the urogenital sinus. The most common anomaly associated with the prostatic utricle is a prostatic utricle cyst. Can be associated with unilaterial renal agenesis, hypogonadism, and cryptorchidism. Prostatic utricle cysts are within the level of the verumontanum and are always in the midline.

**REFERENCE**

**PROSTATIC UTRICLE CALCIFICATION**

**DESCRIPTION**

The prostatic utricle is a remnant of the mullerian ducts. It is a small indentation located at the apex of the verumontanum. Enlargement of the prostatic utricle (EPU) is a rare anomaly which is associated with hypertrophy and is the result of insufficient androgenic stimulation. The incidence of stones in EPU is unknown. 1 study found stones in 8 patients out of 46(18%). Their size ranged from 3–18 mm and they were all composed of hydroxyapatite (HAP) crystal. Treatment includes transurethral utricle fenestration and stone removal. (See also Section II: “Prostatic Utricle Anomalies” and “Calcification, Prostate.”)

**REFERENCE**

**PROSTATITIS, MYCOTIC (FUNgal PROSTATITIS)**

**DESCRIPTION**

A type of nonbacterial prostatitis that is not associated with any specific symptom but is seen as inflammation on prostate biopsy. No specific treatment is necessary. (See Section II: “Prostatitis: Inflammatory (NIH IV).”)

**REFERENCES**

**PROSTATITIS, MYCOTIC (Fungal PROSTATITIS)**

**DESCRIPTION**

A type of prostatitis its caused by fungi and typically associated with systemic mycosis or immunocompromised hosts. Fungal infections can include blastomycosis, coccidiomycosis, cryptococcosis, histoplasmosis, and candida. Diagnosis is based on prostate histology and culture results. For systemic therapy, see the specific invasive agent. (See Section I: “Fungal Infections.”)

**SYNONYM**

Fungal prostatitis

761
PROSTATITIS, NIH CLASSIFICATION SYSTEM

REFERENCE

PROSTATITIS, NIH CLASSIFICATION SYSTEM
DESCRIPTION
A classification proposed by an NIH working group that clearly defines the different types of prostatitis in order to improve the diagnosis and management of the disease. See Section I: “Prostatitis, Acute, Bacterial (NIH I).” “Prostatitis, Chronic, Bacterial (NIH II).” “Prostatitis, Chronic, Nonbacterial, Inflammatory & Noninflammatory (NIH CVCPPS I & II-B)” and Section II: “Prostatitis, Asymptomatic Inflammatory (NIH III).” For an explanation of EPS (expressed prostatic secretion) and V8 (voided bladder urine) see Section II: Startney Test (Three-glass Test, Four-glass Test, Monti-Startney Test).

• Category I: Acute bacterial prostatitis; acute infection of the prostate gland
• Category II: Chronic bacterial prostatitis; recurrent infection of the prostate
• Category III: Chronic non-bacterial prostatitis/CPPS; no demonstrable infection – Category IIIA: Inflammatory CPPS; WBCs in semen/EPS VB3 and/or semen/EPS VB3
• Category IV: Asymptomatic inflammatory prostatitis; no symptoms.

REFERENCE

PROSTATITIS, STRESS
DESCRIPTION
Classically defined as a subset of chronic abacterial non-inflammatory prostatitis/prostatodynia in which a pattern of excessive tension could be identified as a trigger of the syndrome. Symptoms usually responded to anxiolytic agents or behavioral modifications. No longer considered an appropriate term in the NIH Prostatitis classification system.

REFERENCE

PROSTATITIS, TUBERCULOUS
DESCRIPTION
TB of the prostate is rare, and in many cases, it is diagnosed incidentally after a transurethral resection in the prostate chips. Tuberculous prostatitis results from hematogenous dissemination, with an incidence of 10% with men in TB. Symptoms are nonspecific, and the diagnostic evaluation is usually not definitive. On exam, the prostate may be hard, irregular, and nodule. On labs, urine analysis can demonstrate microscopic hematuria or sterile pyuria. Acid-fast bacilli staining of urine and smear has a sensitivity of only 52%; however, culture can take up to 8 wk. A transrectal ultrasound can demonstrate collections or abscess, and an intravenous urogram (IVU) and/or an intravenous urogram (CTU) can be diagnostic. The incidence of TB in patients with obstructive uropathy is approximately 72% of patients with prostatic TB have renal TB.

TREATMENT
• Hospitalization is usually necessary.
• Transurethral resection of the prostate in patients with obstructive uropathy is reasonable.
• Medication includes a 3-drug regimen of sulfamethoxazole/trimethoprim and either ethambutol or streptomycin.
• In complicated cases, 9–12 mo therapy may be required. A negative prostatic biopsy to document successful treatment is recommended.

REFERENCE

PROSTATODYNIA
DESCRIPTION
Classically described as a syndrome complex of multiple complaints including pain in the perineum, lower back, or upon ejaculation; slow stream; and hysteresis. Patients exhibit no evidence of prostatic inflammation. Dysuria, frequency, and systemic signs are usually absent. This term is no longer currently considered to be appropriate and has been replaced by the designation chronic pelvic pain syndrome or CPPS NIH Category II Chronic Abacterial Prostatitis. (See also Section I: “Prostatitis, Chronic, Bacterial, Inflammatory & Noninflammatory (NIH CVCPPS I & II-B).”)

REFERENCE

PROSTITIS, INFECTED PENILE
DESCRIPTION
A dreaded complication of penile prosthesis implantation. Rates of infection range from 1–8%; risk factors include spinal cord injury (SCI), diabetes mellitus especially (if poorly controlled with insulin—<11.5%), history of UTI, and multiple sensitizers must be eliminated and cleansing and toilet habits should be addressed. Treatment of the specific sensitizers is essential. A short course of a cephalosporin is recommended.

REFERENCE

TREATMENT
• Surgical removal
• Irrigation and antibiotic treatment
• Immediate salvage procedures with surgical removal
• Without and immediate replacement have reported good results: Vynnyk intraoperative irrigation with 4 different solutions, including vancomycin,

immediate reimplantation of a new inflatable penile prosthesis, and postoperative outpatient antibiotics, with oral discontinuation or IV vancomycin or oralised.

REFERENCE

PRURITUS, EXTERNAL GENITAILA, MALE
DESCRIPTION
The anogenital area is a common location for pruritic complaints in men and women. Itching can precede the appearance of a rash or other lesion. When the itching results in red, weeping skin with crusts, it is often called “eczematous dermatitis.” Pruritus scroti is a historic term for scrotal itching. The differential diagnosis of itching of the male external genitalia includes:
• Allergic reactions (algae; dermatitis)
• Cancer: Perineal, scrotal, extra-mammary Paget disease (metaplastic adenocarcinoma, found in areas with apocrine sweat glands).
• Candid infection
• Chemical irritants; Detergents, fabric softeners, soaps, creams, ointments, and sexual lubricants
• Dermatologic conditions: Seborrheic dermatitis, psoriasis, eczema (atopic dermatitis), lichen simplex chronicus (LSC)
• Fixed drug reaction
• HIV: Pruritus is 1 of the most frequent symptoms encountered in HIV infection and can even be the 1st clinical symptom
• Infections; Pubic lice (“lice”), scabies
• Nutritional deficiencies; Malnutrition, vitamin deficiencies
• Red scrotum syndrome possibly due to steroid abuse
• Sexually transmitted infections: Genital herpes
• Sunburn/toxicity
• Systemic illnesses: Diabetes mellitus, renal failure
• Testa crisis: Also known as “ringworm of the groin”
• Fixed drug reaction

Some patients manifest itching with or without a demonstrable rash. The skin may appear normal or demonstrate excoriation (lichenification skin thickening) from rubbing, or both. The skin may be subject to mechanical trauma (drying of the skin, scratching, any rubbing of the skin). Sealing antihistamines may limit night symptoms. Some patients may require psychiatric agents for adequate sedation. Antidepressants may be required in patients refractory to standard treatment or those who are experiencing psychiatric disorders. (See also Section II: “Scabies, Urologic Considerations.”)

REFERENCES

762
DESCRIPTION

- Active PSA can also enter the bloodstream where it is rapidly bound and inactivated (completely by prostate inhibitory alpha-1-antichymotrypsin (ACT) and alpha-2-macroglobulin). Most of the PSA in serum exists as a complex with ACT.

- With prostate cancer the disrupted basal membrane allows proPSA and several truncated PSA isoforms direct access to the circulation. This PSA "leaking" into the blood has a larger fraction of the PSA produced by malignant tissue escaping proteolytic processing (ie, activation of proPSA to active PSA and degradation of active PSA to inactive PSA).

- In men with a normal prostate (no cancer or infection), the majority of free PSA in the serum reflects protein inactivated by internal proteolytic cleavage. In contrast, the cleaved fraction is relatively decreased in prostate cancer. Thus, the percentage of free or unbound PSA is lower in the serum of men with prostate cancer (and, conversely, the amount of complexed PSA is higher) compared with those without cancer.

- These observations have resulted in the use of the ratio of free to total PSA and complexed PSA (cPSA) as a means of distinguishing prostate cancer and BPH.

- PSA Collection: The PSA blood sample should be centrifuged, and the serum separated in 2–3 hr. If the assay is not performed within the next 2–3 hr, the serum should be frozen.

- PSA Basic Clinical Considerations: There is a vast amount of clinical data available to guide the clinicians in the use of PSA in patient care. This section highlights some of the published PSA clinical data in a highly annotated form.

- Routine PSA blood testing refers to Total PSA and accounts for increases in prostate volume with age.

- Positive bone scan and PSA: 2.3% PSA bounce (SEE SECTION II, “PSA, GENERAL CONSIDERATIONS”)

- PSA, AGE-ADJUSTED (SEE SECTION II, “PSA, GENERAL CONSIDERATIONS”)
PSA, GENERAL CONSIDERATIONS AND PSA DERIVATIVES

- If measured during external beam radiation therapy for prostate cancer, PSA shows a progressive decline.
- Since prostatic glandular tissue remains after radiation, PSA levels are unlikely to fall to undetectable following radiation therapy unless androgen ablation is also followed. The PSA increases are generally small (0.8 ng/mL) but can sometimes reach 10 ng/mL and may last 6–18 mo. Ironically, bounces may predict a good outcome.
- PSA should fall to a low level after high intensity focused ultrasound (HIFU) and cryotherapy and should not rise on successive occasions. Data is limited using other.
- Salvage radiation following RP, especially those with positive surgical margins receiving treatment when the PSA is low (2.0–1.5 ng/mL) and slowly rising, appear to have best outcomes.
- With metastatic disease or androgen depletion, failure to radiate PSA >4.0 ng/mL. 7 mo after initiation of therapy is associated with a poor prognosis. Median survival >1 yr. With PSA nadir of <0.2 ng/mL, median survival is 6 yr. PSA increase after RP is no radiologic evidence of metastases, a PSA nadir of <0.75 ng/mL/yr in the year prior to diagnosis: Associated with an increased risk of prostate cancer death after RP or radiation. Very high PSA V (≥3.0 ng/mL/yr) is often associated with prostate infiltration as the cause of the elevated PSA.

- PSA doubling time (PSA-DO)
- PSA bounce:
- PSA should fall to an undetectable following radiation therapy unless androgen ablation is also followed. The PSA increases are generally small (0.8 ng/mL) but can sometimes reach 10 ng/mL and may last 6–18 months. Ironically, bounces may predict a good outcome.
- PSA doubling time (PSA-DO):
- PSA bounce:
- PSAV < 2.0–3.9 ng/mL 18.7%
- PSAV > 2.0–3.9 ng/mL 21.3%
- PSAV < 6–7.9 ng/mL 28.6%
- PSAV > 6–7.9 ng/mL 31.7%
- PSAV > 10.0 ng/mL 56.5%
PSA ABCCESS, UROLOGIC CONSIDERATIONS

• Based on the following data there is some support for 1.5 ng/mL being the new “normal” PSA in mid-life.
• In one longitudinal PSA biopsy study baseline PSA level >1.5 ng/mL, the risk of developing prostate cancer increased from 12.3–78.4% at 7 yr.
• PSA >1.5 ng/mL between the ages of 45 and 49 yr accounted for nearly 1/2 of the prostate cancer deaths over the next 30 yr.
• PSA level at age 44–50 yr was very strongly associated with the likelihood of developing prostate cancer during the 20 yr study, the odds ratio for a PCA diagnosis:
  - PSA <0.50 ng/mL, (population average = Odds Ratio 1.0)
  - PSA 0.51–1.0 ng/mL, Odds ratio 2.57
  - PSA 1.0–1.5 ng/mL, Odds ratio 7.02
  - PSA 2.01–3.0 ng/mL, Odds ratio 9.01

REFERENCES

Catriona WJ, Parvin AM, Sanda MG, et al. Multicenter study of Uro-Pro PSA combined with PSA and free PSA for prostate cancer detection in the 2.0 to 10.0 ng/mL PSA range. J Urol 2011;185:1695

PSA, RACE-ADJUSTED (SEE SECTION II “PSA, GENERAL CONSIDERATIONS AND PSA DERIVATIVES”) PSA, RT-PCR

DESCRIPTION: First clinically reported in 1982, RT-PCR is used to amplify mRNA transcripts of PSA. These tiny crib-like species should theoretically only be present in prostate tissues. Extraprostatic tissue of patients with biopsy-proven cancer tissue is tested, including peripheral blood, lymph nodes, and bone marrow, to detect PSA mRNA transcripts and presumably prostate cells in extraprostatic sites. It is being investigated as an assay to detect micrometastasis of prostate cancer before clinical presentation or evidence of disease spread (molecular staging). Its clinical utility as a diagnostic assay remains uncertain and is generally replaced by CTC assays.

REFERENCE

PSA VELOCITY (PSAV) AND PSA DOUBLING TIME (PSADT) (SEE SECTION II “PSA, GENERAL CONSIDERATIONS AND PSA DERIVATIVES”) PSEUDODYSSYNERGIA (HINMAN SYNDROME) DESCRIPTION: A form of detrusor external sphincter dyssynergia in which voluntary contraction of external sphincter occurs during detrusor contraction. It produces the functional voiding dysfunction seen in children with intractable voiding symptoms, men with chronic prostatitis or prostatodynia, and women with urethral syndrome. It may sometimes be a cause of urinary incontinence. This condition is thought to be a learned behavioral abnormality, possibly an uncorrected compensatory mechanism. Diagnosis is based on urodynamic evidence of increased or uncoordinated external sphincter activity during detrusor contraction, usually with simultaneous elevation of intra-abdominal pressure indicating voluntary nature of contraction, without clinical evidence of neurologic deficit. (See also Section II: “Hinman Syndrome” [Hinman–Allen Syndrome, Nonneurogenic Neurogenic Bladder; Ousch Neurogenic Bladder]”)

SYNONYM:
Nonneurogenic neurogenic bladder
Hinman syndrome/Hinman–Allen syndrome in children
Dysfunctional voiding syndrome
Ousch Neuropathic Bladder

TREATMENT:
Children must be motivated to participate in the therapy.
Teach how to void and defer properly.
Timed voiding, voiding diary, double voiding, psychotherapy, and biofeedback may all be appropriate in select children.
Anticholinergics may correct instability.
α-adrenergics may improve outlet resistance.
Psychotherapy, with a change in parental attitude, can greatly improve the situation.
Intermittent catheterization may be necessary in more difficult cases (e.g., with upper tract changes, failure to respond to less invasive measures).
Rhabdovirus

REFERENCE

PSUEDOMYXOMA OVARI-LIKE POSTTHERAPEUTIC ALTERATION IN PROSTATE ADENOCARCINOMA DESCRIPTION: Pseudomyxoma ovarii-like posttherapeutic alteration in prostate adenocarcinoma refers to histologic alterations observed in prostate cancer foci after exposure to total androgen blockade. Changes in neoplastic glands exposed to total androgen blockade characteristically display disorganized acinar atrophy, basal cell hyperplasia, squamous or transitional cell metaplasia, and stromal hypercellularity. Conversely, tumor glands may shrink in size and exhibit mucin. This extravasated mucin resembles pseudomyxoma ovarii. This is an important distinction, as this appearance can be easily confused with mucinous carcinoma. It is important to recognize these posttreatment effects, as they may be the sole histologic evidence of therapeutic response and may guide definitive treatment after neoadjuvant hormone deprivation.

REFERENCE

PSMA (PROSTATE-SPECIFIC MEMBRANE ANTIGEN) DESCRIPTION: A protein with intracellular, transmembrane, and extracellular components of prostatic epithelial cells. PSMA levels are reported to be elevated in hormone refractory prostate cancer and with metastatic disease. Its use as a tumor marker is not as useful in screening as PSA. PSMA is highly sensitive and specific immunomarker for the detection of metastatic prostate carcinoma; however, cells of the small intestine, prostatic renal tubules, and salivary glands also can express PSMA. PSMA may be an in vivo target for imaging utilizing radiolabeled mAb 7E11 (C7T356, capozolid), the Prostate Stem. PSMA is currently being targeted as a therapeutic intervention for advanced prostate cancer including novel AB-directed therapy (PSMA- Specific Membrane Antigen Antibody Drug Conjugate (PSMA ADC)), radiolabeled and anti PSMA vaccines and other immunotherapies.

REFERENCE

PSA ABCCESS, UROLOGIC CONSIDERATIONS

DESCRIPTION: A psa abscess is a discrete abscess or phlegmon in the retroperitoneum, adjacent to the prostate muscle. Usually the consequence of direct spread of infection from an adjacent structure; primary psa abscesses are rare and are a result of hemorrhagic spread. A wide variety of etiologies are reported in the literature, including perirectal abscess; pyelonephritis; postoperative infection following renal, ureteral, or bladder surgery; complications from EIVAS, and urethral carcinoma.
PSOAS HITCH PROCEDURE

metastasis. Clinical presentation includes fever, lower abdominal or back pain, referred lower extremity pain, dyspnea, delirium, altered mental status, and frank hoarseness, and a psoas sign. Rarely, a psoas abscess can directly obstruct the psoas muscle or cause a retroperitoneal inflammatory response. Treatment can initially be medical using antibiotic therapy; however, failure to resolve requires drainage. (See also Section I “Retroperitoneal Abscess, Retroperitoneal Masses and Cysts.”) (Image 0)

REFERENCE

PSOAS HITCH PROCEDURE
DESCRIPTION
A surgical procedure used to replace short segments of distal ureteral loss or in combination with a ureteral reimplantation to provide a fixed posterior bladder wall. The bladder is mobilized and stretched superiorly along the axis of the ureteral defect. The stretched bladder is then sutured to the fascia of the ilio-psoas muscle (Image 0).

REFERENCE

PSORIASIS, EXTERNAL GENITALIA
DESCRIPTION
A chronic papulosquamous skin disease frequently affecting external genitalia, more commonly in males. Generalized involvement is rare. 25–40% of patients with psoriasis. The lesions characteristically are sharply demarcated plaques with silvery, scaly patches. Psoriasis most frequently involves the penis in males and the mons pubis, labia majora, and inguinal crease in females. It is reported to increase the risk of squamous cell carcinoma (SCC) genitale. Treatment includes topical steroids, carprofen and maintaining good hygiene. (See also Section II: “Pruritus, External Genitalia.”)

REFERENCES

PSYCHOGENIC POLYDIPSIA
DESCRIPTION
Psychogenic polydipsia (PPD) is a clinical disorder characterized by polyphagia and polyuria, and is a common occurrence in patients with psychiatric disorders. The underlying pathophysiology of this syndrome is unclear, but multiple factors have been implicated, including a hypothalamic defect and adverse medication effects. Workup for PPD includes a comprehensive evaluation for other medical causes of polydipsia, polyuria, hyponatremia, and the syndrome of inappropriate secretion of antidiuretic hormone. Workup should include plasma and urine osmolality and plasma and urine sodium. Other tests may include a complete metabolic panel, urinary osm, unen, chest x-ray, and CT scan of the head.

TREATMENT
- Treatment for hypovolemia: Fluid restriction, furosemide (diuretics), intravenous normal saline, or hypertonic saline
- Behavioral Treatments: Fluid restriction, therapy, including cognitive techniques
- Drug treatments: Tricyclic antidepressants, chlophedian, risperidone, olanzapine, quetiapine, demerol/lotec, clonidine, ACE inhibitors, conivaptan

REFERENCE

PURPLE URINE BAG SYNDROME
DESCRIPTION
Purple urine bag syndrome (PUBS) is an uncommon disorder in which the urine bags of catheterized patients turn purple or blue. Most patients are bedridden, cognitively impaired, and constipated. The disposition is attributed to indigo and indirubin pigments, which appear purple when combined. The pigments are created when infected tryptophan is exposed to intestinal flora in patients with altered gut motility. PUBS is usually associated with organisms that have indoxyl phosphatase/putrefactive activity (Klebsiella pneumonia, Providencia stuartii, Enterobacter, Proteus mirabilis, Morganella morganii, and E. coli).

TREATMENT
- Antibiotics to treat urinary tract infection
- Catheter change

REFERENCE

PYELITIS CYSTICA
DESCRIPTION
Hypertrophy of urothelial cells into the lamina propria with subsequent fibrosis, giving a cystic appearance. Identical to cystic dysplasia, this lesion occurs in the renal pelvis and calyces. It is a rare condition, usually associated with chronic infection, and is more common in females, usually >50 yr of age. Presenting symptoms are variable, including infections, including fever, dysuria, hematuria, and flank pain. Identified on radiographic studies as multiple small cysts up to 10 mm in diameter in the renal pelvis and calyces, and confirmed by endoscopic biopsy. Not thought to be a premalignant condition, but rare neoplastic conditions. See also Section I “Filling Defect, Upper Urinary Tract [Renal Pelvis and Ureter].”

REFERENCE

PYELITIS GLANDULARIS
DESCRIPTION
In this condition, combined urothelial hyperplasia and metabolic changes of the renal pelvis occur and characteristic glandular structures are seen haphazardly arranged within the lamina propria. These glands are lined by mucin-secreting columnar epithelial cells, which differentiate them from other forms of urothelial hyperplasia such as Von Brunn nests and pyelitis.

766
Cystitis. It is not uncommon to see late hyperplastic changes and pyloric glandularis in a single specimen. Intermittent and luminal mucin can be demonstrated by mucicarmine stain. Most commonly, the overlying surface epithelium remains of the transitional cell type, although metaplastic squamous epithelium or mucous secreting columnar cells may be seen. Pyloric glandularis is commonly focal. Extensive lesions with columnar cell metaplasia of the surface urothelium bear a high resemblance to colonic mucosa. However, the absence of muscularis mucosa helps distinguish these 2 entities. (See also Section I: “Filling Defect, the absence of muscularis mucosa helps distinguish these 2 entities. (See also Section I: “Filling Defect, "Filling Defect, Upper Urinary Tract [Renal Pelvis and Ureter").")

**REFERENCE**

**PYELOGENIC CYST**

**DESCRIPTION** A pyeogenic cyst is a smooth intrarenal diverticulum that communicates directly with the renal pelvis through a calyx or infundibulum. Pyeogenic cysts are lined with transitional cell epithelium. Diagnosis is best made by CT urography or delayed phase or retrograde pyelography showing contrast pooling in the cyst. Asymptomatic pyeogenic cysts do not require treatment. Pain, persistent or recurrent infections, stones, and milk of calcium warrant surgical intervention through uroendoscopic, percutaneous, laparoscopic, or open surgical techniques.

**REFERENCE**

**PYOCYSTIS**

**DESCRIPTION** Pyocystis is a severe UTI of the bladder associated with a nonfunctioning bladder or in patients with chronic colonic anemia. Also called vesical enpermia. Commonly seen (20–30%) in patients with a neurogenic bladder treated with urotherapy. Pyocystis should be suspected in patients with a nonfunctioning bladder or in those who are oligo- or amenorrheic with persistent signs of infection. Bladder catheterization should be performed and the urine cultured. A positive culture is diagnostic; however, imaging studies such as CT may reveal diagnostic signs such as bladder wall thickening. Conservative medical therapy is often adequate, comprised of specific antibiotics and bladder drainage. Some advocate periodic bladder irrigations and instillations with antibiotic solutions therapy are directed by the specific organisms isolated. Bladder irrigation with either saline or an antibiotic solution benefit is not clear. Cystectomy is reserved for refractory pyocystis.

**REFERENCE**

**PYONEPHROSIS**

**DESCRIPTION** Infected, obstructed collecting system with grossly purulent drainage and suppurative necrosis of renal parenchyma. This can be a chronic, indolent infection, but it usually presents acutely with sepsis, flank pain, and ipsilateral loss of renal function. Immediate aspiration with retrograde or percutaneous puncture is essential.

**REFERENCE**

**PYOSPERMIA**

**DESCRIPTION** The World Health Organization defines pyospermia as >1 x 10^9 WBCs/cell (either peroxidase or by immunohistologic methods). Pyospermia (also referred to as leukospermia) has multifactorial causes, including infection, inflammation, and autoimmunity, and is considered to be 1 of the causes of male infertility. The short half-life of polymorphonuclear neutrophils (PMNs) in semen makes them a major source for factors that can be harmful to sperm. The differential diagnosis of symptomatic pyospermia includes infection, autoimmune disease, and inflammation of the accessory sex glands and lower male urogenital tract. Urogenital infections include acute and chronic prostatitis, seminal vesiculitis, epididymitis, orchitis, urethritis, urethral strictures, stone disease, foreign bodies, upper UTI, retrograde ejaculation, localized sepsis of the adjacent lower UT tract, and asymptomatic bacteriuria. The chronic infections that may result in pyospermia include fungal, mycobacterial, and conjunctival lesions causing infection of the urogenital tract. Autoimmune diseases that affect the urogenital tract include Behçet syndrome and Reiter syndrome (Reactive arthritis/mucocutaneous arthritis triad). There is no defined medical management of pyospermia once the specific cause cannot be reliably identified. Options include antibiotic treatment (doxycycline, trimethoprim-sulfamethoxazole, ciprofloxacin) and other medications such as calcium dibromide, propylidione, n-acetyl-c-cysteine, glutathione, and vitamins C and E. Removal of cause and primary predisposing factors include the correction of any congenital or acquired defect in the GU tract, harboring infection and inflammation, se颠覆ous reflux, prostatitis obstructive and infection, retrograde ejaculation, and urethral valves. Although antibiotics are a commonly used empiric therapy, studies have not confirmed their benefit, and a high risk of spontaneous resolution occurs without specific therapy. (See also Section II: “Semen Analysis, Abnormal Findings and Technology.” "Semen Leukocytes.")

**REFERENCE**

**Q-TIP TEST**

**DESCRIPTION** The Q-tip test is useful to evaluate the vesical neck and evidence of hypermobility in the evaluation of urinary incontinence in the female. A cotton-tipped applicator is advanced per urethra to the level of the bladder neck and observed for changes in angle during straining maneuvers. Hypermobility suggests that a bladder neck suspension may restore continence.

**REFERENCE**

**QUAKEL CORPUSAL SHUNT**

**DESCRIPTION** Used for the treatment of priapism. Through a crural-perineal approach, a longitudinal incision is made in the corpus spongiosum urethrae (making sure not to completely traverse and injure the urethra), and a parallel incision is made in the corporal body. After irrigating stagnant corporal blood, these 2 incisions are anastomosed.

**REFERENCE**

**RADIATION EXPOSURE GUIDELINES**

**DESCRIPTION** The National Council on Radiation Protection and Measurements has recommended maximum permissible dose limits for occupational exposure to members of the public, which apply to the sum of the effective doses from external radiation and the committed effective doses from internal exposures. Occupational exposure

- The individual worker’s Lifetime effective dose should not exceed 0.5 mSv in any 1 yr.
- An annual effective dose limit of 50 mSv.
- An annual dose limit of 150 mSv for the lens of the eye.
- An annual dose limit of 500 mSv for localized areas of the skin and the hands and feet.
- A monthly dose limit of 0.5 mSv to the fetus once a pregnancy is declared.
- No occupational exposures should be permitted until age 18 yr.

Public exposure

- An annual effective dose limit of 1 mSv for continuous exposure and 5 mSv for infrequent exposure.
- An annual dose limit of 50 mSv for the hands and feet and localized areas of the skin and 15 mSv for the lens of the eye.
- For educational and training purposes involving people aged >18 yr, an annual effective dose limit of 1 mSv.

**REFERENCE**

Radiation Proctitis, Urologic Considerations

Radiation proctitis refers to radiation-induced injury to the rectal mucosa beginning 3 mo after treatment has ended. The incidence varies from 5–20%. Predisposing factors include prior lower abdominal surgery, diabetes, hypertension and possibly chemotherapy. Symptoms of radiation proctitis include tenesmus, bleeding, low-volume diarrhea, rectal pain, and loss of continence. Treatment is made with sigmoidostomy.

**TREATMENT**
- Correction of fistula
- Sacrouterine enemas
- Argon laser
- Bipolar electrocoagulation
- Sucralfate enemas
- Corticosteroids
- Surgery

**REFERENCE**

**Radiation, Renal and Retroperitoneal, Urologic Considerations**

**DESCRIPTION**
Radiation therapy (RT) for RCC as primary therapy is ineffective, but it is useful for palliation of bone metastases. It can be utilized for renal carcinomas or lymphoma. Retroperitoneal radiation is used for seminoma but not for nonseminomatous tumors. Nonseminomatous germ cell tumors (NSGCT) are generally less radiosensitive, and RT is typically not used. Side effects of renal and retroperitoneal RT include retroperitoneal fibrosis, ureteral stricture or obstruction, hydronephrosis, enteritis, cardiovascular complications, and secondary malignancy.

**REFERENCE**

**Radioisotopes, Urologic Considerations (Strontium-90, Samarium-153, Radium-223)**

**DESCRIPTION**
Strontium-90 and Samarium-153 are ε-emitters which can emit high linear energy transfer; may be halted by an aluminum plate. 100-1000 hits to kill cells; single strand breaks that are more easily repaired.

**REFERENCES**

**Rapid Plasma Reagin (RPR) Blood Test**

**DESCRIPTION**
The RPR test is a screening test for syphilis (T. pallidum infection). RPR detects serum antibodies to substances released by cells damaged by T. pallidum. It is 78%, 100%, and 95% sensitive in screening for primary, secondary, and tertiary syphilis, respectively. If a patient tests positive, a confirmatory treponemal antibody test should be ordered. False positives can be seen in viral infections, and HIV can cause a false negative reaction.

**REFERENCES**

**Raz Bladder Neck Suspension (Urethroplasty)**

**DESCRIPTION**
This is 1 of many surgical bladder neck suspension techniques aiming to fix the vesicourethral junction in a physiologic position to correct genuine stress incontinence in females. It is a modification of the Pereyra needle suspension. Through an inverted U-shaped incision in the anterior vaginal wall, the operator performs (1) retropubic urethropexy, (2) fundopexy guidance of a double- stranded suture carrier placed through a suprapubic opening, and (3) placement of helical reabsorbable sutures through the urethropexic ligament, otherwise known as the endopelvic fascia. Cystoscopy is performed after the sutures are placed. Best suited for patients with urethral and bladder neck hypermobility and no cystocele.

**REFERENCE**

**Raz Vaginal Wall Slung**

**DESCRIPTION**
Technique to treat urinary incontinence due to intrinsic sphincter dysfunction or anatomic incontinence, this is a modification of the original Raz bladder neck suspension. This technique provides support for both the bladder neck and mid-urethra. In addition to the principal maneuvers described in the Raz urethrolysis, the author incorporates a patch of anterior vaginal wall with the suspension sutures at the level of the bladder neck, which, in effect, creates a hammock that supports a backboard to the bladder neck and mid-urethra.

**REFERENCE**

**Reactive Arthritis/ Reactive Arthritis Triad (Formerly Reiter Syndrome)**

**DESCRIPTION**
The preferred term today is reactive arthritis, a classic triad of polyarthritides, conjunctivitis, and nongonococcal urethritis; in women, cervicitis. Anterior uveitis and skin or genital rash may be seen. Thought to be a systemic inflammatory response triggered by microbial infection in the GI or GU tracts, the condition is a member of the spondyloarthritic family of disorders. The arthritis is usually asymmetric, with predominately lower extremity involvement. Joint aspiration is typically sterile. Association with HLA-B27 is noted, and may confer susceptibility. 2 forms exist: Sexually transmitted, in which symptoms emerge 10-14 days after exposure. Causes include C. trachomatis, Ureaplasma urealyticum. The overall prognosis is good, with spontaneous remission or relapse following NSAID therapy within 6-9 mos of onset. A small proportion have chronic persistent arthritis, a few will develop ankylosing spondylitis more frequent if HLA-B27 positive. Clinical treatment includes supportive care, NSAIDs, intra-articular or systemic corticosteroids for polyarthritides. Antibiotic treatment is initiated for identified organisms, if possible, such as C. trachomatis doxycycline 100 mg PO bid for 7-14 days. (Note: The name change from Reiter syndrome to reactive arthritis is based in part on allegations that Dr. Reiter was an un-convicted war criminal.)

RENOLOGY, NORMAL RADILOGRAPHIC FINDINGS (SIZES, CALYCES)

RECTOCELE, UROLOGIC CONSIDERATIONS

DESCRIPTION Recesses generally presents as a posterior bulge in the perineum in the setting of proteus. It can present with urological symptoms including sexual dysfunction and voiding symptoms, as well as constipation. If a patient presents with voiding dysfunction, a urodynami study should be performed with the recessed redundant to confirm the patient’s underlying urodynamic parameters. Prior to repair, it is important to determine if there is a deviation of enterocoe or cystal, to determine the appropriate reconstructive procedure. Treatment can be conservative using a vaginal pessary or surgical fixing of 1 or several techniques, including open or laparoscopic, transvaginal, or endoscopic. (See reference “Pelvic Organ Prolapse (Cystocoele and Entocoele”).)

REFERENCE Hall GM, Shanmugan S, Nobel T, et al. Symptomatic muscle tumors and renal cell cancer as a result of the mutations in the fumarate hydratase gene. The term muscle tumors (leiomyomas) in the skin and uterus increased predisposition to develop benign smooth leiomyomatosis, also known as Reed syndrome, is an initial with gabapentin a 2nd-line therapy. (See also Section II: “Scrotal Skin Lesion.”)

RED SCROTUM SYNDROME

DESCRIPTION The external genitalia can be affected by many inflammatory processes such as atopic and irritant dermatitis, psoriasis, or syphilis. A common disease Red Scrotum Syndrome (RSS) affects makes in their 2nd half of life and typically runs a chronic course. It may represent a localized phenotypical expression of erythromelalgia. RSS is characterized by persistent redness of the anterior 1/2 of the scrotum and may also involve the base of the penis. Symptoms include itching, burning, and pain sensations. It can develop after prolonged use of topical corticosteroids. It is often mistaken for eczema but itching is not common in RSS. Burning and hyperesthesia are typical in RSS and are not usual with eczema. The pain is aggravated by warmth, relieved by cold. Differential diagnosis includes atopic dermatitis, contact dermatitis, psoriasis, lichen simplex, and Langerhans cell histiocytosis among others. Oral dicyclomine is used initially with gabapentin a 2nd-line therapy. (See reference “Rectocele: Urologic Considerations.”)

REED SYNDROME

DESCRIPTION Multiple cutaneous and uterine leiomyomas, also known as Reed’s syndrome, is an autosomal dominant condition. Individuals have an increased predisposition to develop benign smooth muscle tumors (leiomyomas) in the skin and uterus. Survivors of these patients are at risk for renal cell cancer and have been determined to have mutations in the Fumarate hydratase gene. The term hereditary leiomyomatosis and renal cell cancer refers to tumors with an increased prevalence of smooth muscle tumors and renal cell cancer as a result of the fumarate hydratase genetic defect. (See also Section II: “Uterine Leiomyomas, Hereditary” and “Renal Cell Carcinoma, Familial.”)

REFLUX NEPHROPATHY

DESCRIPTION Racial scarring secondary to reflux of urine or infected urine from the bladder to the kidneys. Girls are at increased risk of developing reflux nephropathy because of the increased incidence of UTIs. Most cases are associated with vesicoureteral reflux, and children are usually asymptomatic or may present with infection, hypertension, or renal failure in cases of severe scarring. Usually a radiographic diagnosis, US and voiding cystourethrography identify the reflux, and renal scarring is detected radiographically by a conical imaging agent such as DMSA technetium99m (dimercaptosuccinic-acid). Treatment is directed at the cause (such as vesicoureteral reflux antibiotic suppression or surgical correction). (See also Section I: “Vesicoureteral Reflux,” and Image 60.)

REIFENSTEIN SYNDROME

DESCRIPTION A form of incomplete male pseudohernphroditism, usually presenting with penoscrotal hypoplasia and frequently cryptorchidism at birth, azoospermia and incomplete virilization at puberty, and infertility and gynecomastia at or after puberty. Causation by mutations in the SFRS5 binding domain of androgen receptor, with varying degrees of androgen receptor dysfunction. Patients are usually assigned to male sex at birth, and they exhibit elevated levels of testosterone and inhibin B. Surgical repair of hypospadias and cryptorchidism as the treatment and supplemental testosterone is not beneficial. (See also Section II: “Androgen Insensitivity Syndrome (AIS or Androgen Resistance Syndrome), Complete and Partial.”)

SYNONYMS

- Isolated Mildly-Deferens Syndrome
- Type 1 incomplete male pseudohernphroditism

REINKE CRYSTALS

DESCRIPTION Cryotopically crystallized inclusions found in human leydig cells. The crystals are large, distinctive, and easily visible under light microscopy. It has been noted that their numbers increase with age, their function or significance is unknown.

RENAL ANATOMY, NORMAL RADILOGRAPHIC FINDINGS (SIZES, CALYCES)

REFERENCE The most common renal epithelial neoplasms and found in 1.6–7% of autopsies. Controversial if these are small adenocarcinomas. Stenosis diagnostic criterion include papillary, sclerotic, or tubulopapillary architecture, <5 mm and no resemblance to any renal malignancy.

REFERENCE This condition is defined by the cephalic absence of 1 or both kidneys.

REFERENCES

- Bilateral renal agenesis. Incompatible with life as kidney function in utero is necessary in development of the lungs, infants born with bilateral agenesis have hypoplastic lungs, oligohydramnios, anuria, and renal failure, as well as a well-described group of physical findings such as a flattened nose, low-set ears, bowed knees, and a small chest collectively referred to as Potter syndrome. Bilateral agenesis is reported in 1 in 3,000 births but the actual incidence is unknown since many fetuses are believed to spontaneously abort without a diagnosis.

- Unilateral renal agenesis. In contrast, unilateral agenesis is usually asymptomatic and is often undiagnosed throughout life. It occurs in 1 in 1,100 births, and is more common in males (1.8:1); the left kidney is more commonly missing. Commonly associated with mullerian duct, Wolffian duct, and urogenital system anomalies. The most common anomalies are uterine anomalies, renal anomalies (cystic kidneys, horseshoe kidney), and female sex reversal. Bilateral renal agenesis is also associated with anomalies of other systems (such as cardiovascular in 30% valvular or septal cardiac anomalies, GO in 20%, imperforate anus or absence of anus or esophagus, and vertebro or pharyngeal anomalies. If diagnosed, some clinicians propose yearly screening of BP and urinary protein levels because of the risk of hypertension, renal insufficiency, and proteinuria found in some adult studies. (See also Section I: “Potter Syndrome/Potter Facies.” and Image 29.)

REFERENCE The kidney can be imaged by plain film, US, CT, MRI, radionuclide scanning, or angiography, either by venography, arteriography, or retrograde. A normal adult kidney should measure 10–15 cm vertically, 5–7 cm transversely, and 3 cm vertically.
**RENAL ARTERY ANEURYSM**

DESCRIPTION: A renal artery aneurysm is defined as a dilated segment of renal artery that exceeds twice the diameter of a normal renal artery. Although rare, the diagnosis and incidence of this entity have been steadily increasing due to the routine use of cross-sectional imaging. Incidence ranges from 0.3–1.0% on radiographic studies, accounting for 1% of all arterial aneurysms and 10% of renal aneurysms. They are commonly bilateral or multiple and occur typically in the 5th–6th decades of life, slightly more frequently on the right. They are associated with hypertension, HTN, flank pain, hematuria, or an incidental finding on imaging. Presentation is usually secondary to occlusion of aneurysmal segments is reserved for high-risk surgical candidates. Occlusion of aneurysmal segments is reserved for high-risk surgical candidates. Occlusion of aneurysmal segments is reserved for high-risk surgical candidates. Occlusion of aneurysmal segments is reserved for high-risk surgical candidates.

**TREATMENT**
- Microsurgical repair or percutaneous embolization is recommended for repair of renal artery aneurysms (RAAs) >2 cm. Spontaneous rupture, or asymptomatic rupture in high-risk patients is not recommended.
- Aneurysms associated with pheochromocytoma, ectopic adrenocortical neoplasia, paraganglionic, renal pelvic clear cell RCC or testicular germ cell neoplasia may be more aggressive.
- Unruptured aneurysms greater than 2 cm can be observed if symptomatic.
- Angioplasty and stenting for aneurysms greater than 4 mm in size should be considered for high-flow lesions.
- Aneurysms >5 mm in diameter require surgical intervention.
- Intrarenal aneurysms: Surgical intervention.
- REFERENCES

**RENTAL ARTERY FIBROMUSCULAR DYSPLASIA**

DESCRIPTION: Fibromuscular diseases of the renal arteries account for 1/3 of cases of renovascular hypertension. Treatment consists of antihypertensive therapy for asymptomatic individuals and percutaneous balloon angioplasty for patients with indications for intervention. Patients with macroaneurysms should be treated with either a covered stent or surgery. BP control with ACE inhibitor or angiotensin II receptor blocker. 4 pathologic entities have been described:
- Intimal fibroplasia
- Medial fibroplasia
- Perimedial fibroplasia
- Intimal hyperplasia

- Angioplasty is the treatment of choice.
- Spontaneous rupture is rare, but risk is increased during pregnancy.
- Prompt repair is advised because of the progressive nature of the disease.

**TREATMENT**
- Repair includes primary repair with excision of the aneurysmal segment, or aortorenal bypass with autologous or bypass with a bypass.
- Aneurysms >2 cm can be observed if symptomatic.
- Angioplasty is the treatment of choice.
- REFERENCES

**RENAL CANCERINOID TUMOR**

DESCRIPTION: Rare tumor derived from enterochromaffin or atrial precursor uptake and decarboxylation (APUD) cells, occurring most commonly in the GI tract and lung, but also in ovaries, testes, thyroids, parotis, and hepatobiliary system. Primary renal lesions are extremely rare, with only 32 cases reported. The lesions are thought to originate in renal collecting cells undergoing intestinal metaplasia or from renomedullary epithelial cells within the kidney. Hormones (62) are secreted and may have a markedly elevated risk of carcinoid tumor, although still very rare, and may have a more benign course.

**TREATMENT**
- Primary renal lesions are extremely rare, with only 32 cases reported. The lesions are thought to originate in renal collecting cells undergoing intestinal metaplasia or from renomedullary epithelial cells within the kidney. Hormones (62) are secreted and may have a markedly elevated risk of carcinoid tumor, although still very rare, and may have a more benign course.

**RENAL CELL CARCINOMA, CLEAR CELL**

DESCRIPTION: This represents up to 85% of renal tumors. It is thought to arise from the proximal renal tubule unit and is characterized by a lipid content in over 90% of cases. It has a better prognosis than other RCC histologies. Chromophobe RCC is difficult to distinguish from oncocytoma on biopsy, making definitive diagnostic difficult without a complete pathologic exam. C-kit and epithelial-related antigen (MOC31) may be helpful in the distinction between chromophobe RCC and renal oncocytoma. (See also Section “Renal Cell Carcinoma, General” and Image 42.)

**SYNONYMS**
- Hypernephroma (once thought to be adrenal origin)
- Grawitz tumor

**REFERENCES**

**RENAL CELL CARCINOMA, FAMILIAL**

DESCRIPTION: Approximately 2% of renal cell carcinomas (RCC’s) can be inherited. Familial renal cancers are characterized by an early onset compared with sporadic cases and frequently comprise bilateral and multifocal tumors. Moreover, extrarenal features suggestive of a described familial renal cancer syndrome might be present. See table for common renal familial syndromes. (See also Section “Renal Cell Carcinoma, General.”)

**SYNONYMS**
- Hereditary cancer syndrome

**REFERENCES**

**REFERENCES**
- Molecular data suggests that many of these patients with RAs >2 cm can be observed if symptomatic.
- Angioplasty and stenting for aneurysms greater than 4 mm in size should be considered for high-flow lesions.
- Aneurysms >5 mm in diameter require surgical intervention.
- Intrarenal aneurysms: Surgical intervention.

RENAL CHELSTEROL EMBOLISM SYNDROME

DESCRIPTION: The syndromic features of cholesterol embolism are usually the result of severe hypertension. It is increasingly associated with thrombolytic therapy. Clinical findings include severe hypertension, digital gangrene, livedo reticularis, cerebrovascular accidents, GI hemorrhage or infarction, bowel perforation, retinal ischemia, and mental retardation.

RENAL CHELSTEROL EMBOLISM SYNDROME

DESCRIPTION: Cholesterol microembolism (also called choleterol embol and cholesterol crystal embol of the kidney) is an uncommon cause of hypertensive emergencies, affecting primarily elderly men with atherosclerotic vascular disease. It is increasingly associated with thrombolytic therapy. Clinical findings include severe hypertension, digital gangrene, livedo reticularis, cerebrovascular accidents, GI hemorrhage or infarction, bowel perforation, retinal ischemia, and mental retardation. Diagnosis is most often made from clinical history, physical exam, labs findings, and imaging studies.

DESCRIPTION
These benign vascular neoplasms are most frequently affected. Treatment is supportive and preventative with management of hypertension and albuminuria through control of the underlying pathology.

CAUSES
- Angiographic manipulation
- Anticoagulant medications
- Cardiovascular surgery
- Traumatic
- Spontaneous

RENALE MEDULLARY CARCINOMA

DESCRIPTION
This is an aggressive renal malignancy limited almost exclusively to young black patients with sickle cell trait and, less commonly, sickle cell disease. Typical age of presentation is 21–24 yr of age with a peak prevalence of 75% occurring in the right kidney. Genetic testing has suggested a potential association with various chromosomal anomalies. It is considered a variant of collecting duct carcinoma. Patients usually present with gross hematuria, flank pain, an abdominal mass, and/or weight loss. Metastases in the central nodes to brain are often the initial finding. Therapy in the senior population should prompt evaluation for renal medullary carcinoma. Excludes an abdominal mass at a centrally located infrarenal lesion resembling the renal sinus with peripheral calcifications. tumor ranges from 4–12 cm (averaging 7 cm) and usually associated with hemorrhage and necrosis. Metastatic disease is commonly present at diagnosis. Surgical resection is not usually curative. There is a limited experience in the treatment of metastatic disease. Survival after diagnosis is usually 6–12 mo (Image No. 94).

REFERENCE

RENALE OSTEODYSTROPHY

DESCRIPTION
Renal osteodystrophy is defined by the National Kidney Foundation as bone morphology abnormalities observed in chronic kidney disease. Several changes can occur, including osteitis fibrosa cystica due to secondary hyperparathyroidism, osteomalacia, or low bone turnover. The most common presenting symptoms are bone fracture and pain, and usually occurring once lower is on dialysis. Treatment may include treating hyperparathyroidism, calcitriol, vitamin D analogs, calcimimetics, or parathyroidectomy.

REFERENCE

RENALE PSEUDOTUMOR

DESCRIPTION
A bizarre condition of the kidney mimicking a renal neoplasm on radiographic studies. Most commonly a hyperintense column of Adenoma hypertrophy (adenoma) a prominent medullary column usually located between the upper and middle pole calyces that can appear as a renal mass but is homogeneous with surrounding renal parenchyma, with normal appearing calyces. Other conditions giving appearance of renal tumor include persistent fetal lobulation, medullary dysplasia, and renal dysplasia. Metastases in the central nodes to brain are often the initial finding. Therapy in the senior population should prompt evaluation for renal medullary carcinoma. Excludes an abdominal mass at a centrally located infrarenal lesion resembling the renal sinus with peripheral calcifications. tumor ranges from 4–12 cm (averaging 7 cm) and usually associated with hemorrhage and necrosis. Metastatic disease is commonly present at diagnosis. Surgical resection is not usually curative. There is a limited experience in the treatment of metastatic disease. Survival after diagnosis is usually 6–12 mo (Image No. 94).

REFERENCE

RENALE SINUS ABNORMALITIES

DESCRIPTION
The renal sinus is a central space usually located in the renal pelvis. It is usually filled with adipose tissue, lymphatic channels, nerve fibers, and fibrous tissue. Lesions that may develop in the sinus could be benign, including parapelic simple cysts, lipomatosis, cysts, urinomas, and various lesions such as renal artery aneurysm or AV fistula. Malignant tumors originating in renal pelvis or pararenchyma, such as TCC and RCC, may develop in the renal sinus. Primary tumors, such as hemangioma, fibroma, kystoma, and MRH are rare but may develop in the space.

REFERENCE

RENALE TRANSPLANT TYPES (STANDARD/EXTENDED/ DONOR AFTER DEATH)

DESCRIPTION
Renal transplant donors can be by living donors or deceased donors. Decreased donors are individuals who meet the criteria for brain death, but whose organs are being perfused by life support methods, allowing adequate time for procurement. Donor after cardiac death is an expanded criteria donor. Nonheart beating donor (NHBD) death is characterized by irreversible absence of circulation. NHBDs are less than ideal because organ function is impaired because organ function is impaired during prolonged periods of circulatory arrest. Nearly 70% of all renal transplants are from deceased donors. Living donors can be either related or unrelated. On prospective evaluation, normal renal function after donation is the goal. In line with this, the better functioning kidney is left with the donor. RAH-identical siblings have the highest graft survival rates followed by 1-haplogene siblings. In paired donor exchange, also known as kidney swap, 2 kidney recipients exchange willing donors whom they are willing to receive. This allows the donors to provide 2 recipients with grafts where previously no transplant would have been possible. Overall, living donor grafts have higher survival rates, with 80% surviving at the 5-yr mark compared to 67% of deceased-donor grafts (Image 49).

REFERENCE

RENALE TRANSPLANTATION AND NEOPLASIA

DESCRIPTION
The transplant recipient has an elevated risk of cancer. There is a very small risk of primary malignancy harbored in the graft being transplanted to the recipient. The most common malignancies that form after transplantation are de novo malignancies. They are thought to occur secondary to chronic use of immunosuppressive drugs. After 10 yr of immunosuppressive therapy, kidney transplant recipients have a cumulative incidence of cancer as high as 20%. The most common are Kaposi’s sarcoma

de novo cancers after transplantation: Results from
a cohort of 7217 kidney transplant recipients, Italy

smooth muscle element of the renal vein, occurring
most commonly on the left side. The highest incidence
is seen in 60–69 year olds and is twice as common in
women. Only 32 cases of renal vein leiomyosarcoma
have been reported in the literature. The renal vein is
the most common site of venous leiomyosarcoma
outside of the vena cava. Presenting symptoms include
flank or abdominal pain, weight loss, and a palpable
abdominal mass. 3-dimensional abdominal imaging
imaging reveals a homogeneous, well-circumscribed
mass at or near the renal hilum, commonly encasing
the renal vein. Mean survival is 28 mo, with an
aggressive malignant pattern to distant sites, including
lung, liver, bone, skin and soft tissue, and brain.

RENAL TUMORS, WHO 2004
CLASSIFICATION
DESCRIPTION The 2004 World Health
Organization (WHO) classification of the adult renal
epithelial neoplasms replaced the previous 1998 WHO
classification. It incorporates other classifications
(Mainz, Heidelberg) and describes entities based on
both pathologic and genetic analyses. (See table)

WHO (2004) Classification of All Renal Tumors
Renal cell tumors
Clear cell renal cell carcinoma
Multilocular clear cell renal cell carcinoma
Papillary renal cell carcinoma
Chromophobe renal cell carcinoma

RENAL–RETINAL SYNDROME
DESCRIPTION Also called juvenile
nephronophthisis with retinal disease or Senior-Loken
syndrome (SLS) it is a subtype of juvenile
nephronophthisis. (See Section II: “Juvenile
Nephronophthisis.”) It is an autosomal recessive
disease characterized by development of retinitis
pigmentosa- or Leber congenital amaurosis-like retinal
dystrophy and a medullary cystic kidney disease. These
patients have concomitant retinitis pigmentosa, which
is slowly progressive and bilateral, with retinal
degeneration. Rods are affected, leading to defective
night vision that becomes symptomatic in early
childhood. The disc may look yellow and waxy.
Treatment is supportive, with renal replacement
therapy as needed.

SYNONYMS

r Juvenile nephronophthisis with retinal disease
r Senior–Loken syndrome

syndrome: A syndromic form of retinal dystrophy
associated with nephronophthisis. Vision Res.

RENIN, PLASMA AND RENAL
VEIN
DESCRIPTION In suspected renovascular

hypertension, an elevated renin level of >50% in the
renal vein compared to the renal artery plasma level
(estimated from the IVC renin level) of the affected
kidney is diagnostic. Individual renal veins can be
sampled to isolate ischemic individual renal segments
using this same technique. Normal, morning plasma
renin activity for seated subjects ranges from about
1– 4 ng/mL/h (0.8–3.0 nmol/L/h). Corresponding
active renin concentrations are 8–35 mU/L. Renin is
increased with diuretics (including spironolactone),
dihydropyridine calcium channel blockers, angiotensin
converting enzyme inhibitors and angiotensin receptor
antagonists. Levels are decreased by β-blockers,
clonidine, or α-methyldopa (all of which reduce
β-sympathetic stimulation of renin release), or
nonsteroidal anti-inflammatory agents (which promote
salt retention and also inhibit renal prostaglandin
production).
r Normal renin: Secondary adrenal insufficiency (ie,
hypopituitarism or isolated ACTH deficiency);
Cushing syndrome, but they can be low when there
is a marked degree of hypercortisolism.
r Low renin: Primary aldosteronism; with
11β-hydroxylase or 17α-hydroxylase deficiency (due
to mutations in CYP11B1 and CYP17, respectively),
which are hypertensive forms of CAH; primary
glucocorticoid resistance; DOC-producing adrenal
tumors; ectopic ACTH syndrome.


REFERENCES

RENO-ALIMENTARY FISTULA
DESCRIPTION
A broad group of nonanatomic communications between the upper urinary collecting system and the alimentary canal, with nephrocolic and nephrobronchial fistulas being the most common presentations. Symptoms vary from GI symptoms such as nausea, vomiting, and diarrhea, to recurrent UTIs with flank pain and fever. Retrograde ureterography is generally needed to visualize the fistula. (See also Section II: “Fistula, Enterovesical.”)

CAUSES
• Renal inflammatory disease (acute or chronic)
• Malposition of other intestinal or visceral organs
• Iatrogenic (eg, percutaneous surgery)
• Trauma
• Urol disease

TREATMENT
• Conservative: Stenting or nephrostomy tube
• Nephrectomy with removal of fistula tract and bowel resection

REFERENCE

RENO-BRONCHIAL FISTULA
DESCRIPTION
Fistulas communicating between pleural cavity and kidney, associated with pyelonephritics and perirenal abscesses. Usually presents with flank or abdominal pain with an (isolated) pneumonia. Patients commonly have a history of pyelonephritis or abdominal abscess. Fistulas involving the kidney are most commonly caused by iatrogenic trauma. These may include perirenal nephrostomy or nephrothoracostomy tract placement. Renobronchial fistulas usually develop from an upper pole approach to the kidney, where the pleural cavity may be traversed. It can involve pleural space alone or one into lung parenchyma and bronchial tree. Diagnosis is made with CT.

SYNONYMS
• Nephrobronchial fistula
• Renal, bronchopulmonary fistula

CAUSES
• Pyelonephritis with peripheric abscess
• Xanthogranulomatous pyelonephritis
• Most common pathogens: E. coli and Proteus sp account for 1/3 of cases
• Tubercular infections also reported
• Urinogenital trauma: Perrenostasis nephrostomy, nephrotomy tract placement

TREATMENT
• Percutaneous or open drainage and antibiotic therapy usually required

REFERENCE

RENO-MEDULLARY INTERSTITIAL CELL TUMOR
(ADENOCARCINOMA)
DESCRIPTION
Also referred to as medullary fibroma and renal hamartoma, this is a benign renal interstitial cell neoplasm. Rarely they are large and symptomatic. It is a common incidental finding in as many as 5% of adults at autopsy. Renomedullary interstitial cell tumor arises from interstitial cells of the medulla. They do not appear to have any effect on blood pressure. At gross exam, medullary fibromas are white or gray nodules within the renal pyramids. At histologic exam, this tumor is characterized by variable-sized spindle cells in the background of a lymphocytic stroma. It can be seen on CT as a well demarcated noncalcified hypoattenuating cold mass within the renal medulla. Although it is a benign tumor, it is difficult to differentiate this lesion from other malignancies of the kidney on radiologic basis and heroic many patients undergo radical nephrectomy (Stuart OS).

REFERENCES

REPERFUSION INJURY, RENAL (RENAL ISCHEMIA AND REPERFUSION INJURY)
DESCRIPTION
Ischemic acute kidney injury (AKI) is a syndrome that develops following a transient drop in total renal blood flow to the kidney. Although reperfusion is essential for the survival of ischemic tissue, there is evidence that reperfusion itself causes additional cellular injury after a period of ischemia. Therefore, strategies that can provide protection against ischemic injury may be beneficial to such patients. Studies comparing partial nephrectomy with and without clamping show that ischemia is associated with an increase in proteinuria and albuminuria in patients with ischemia. However, advanced protection and reperfusion strategies have proven beneficial. Clamping decreases the incidence of renal failure by decreasing the amount of renal ischemia. Although a minority of patients may experience serious complications from clamping, many patients also experience relatively mild complications, such as hypertension, hypotension, and tachycardia. Therefore, clamping may be a useful tool in managing AKI.

REFERENCES

RETE TESTIS, ADENOCARCINOMA
DESCRIPTION
Adenocarcinoma arising from the rete testis is an extremely rare tumor, typically occurring in older men. The majority of patients present with a painless mass in the testis, often mistaken for a spermatic cord cyst or epididymal cyst. On rare occasions, a patient may present with a testicular mass and an elevated hCG level. The tumor most commonly affects the rete testis, which is the epididymal portion of the testis. It is a highly malignant tumor arising from the rete testis, which is composed of a network of capillaries and lymphatics that drain the testis. It is also known as testicular adenocarcinoma. The tumor is typically unilateral and may present with symptoms such as pain, swelling, and a mass. It is important to note that rete testis adenocarcinoma has a more aggressive behavior compared to other testicular tumors. It is important to diagnose and treat this tumor promptly to improve the outcome for the patient.
commonly presents with a painless scrotal mass or symptoms related to metastasis. Pathology reveals papillary adenocarcinoma in the rete testis, commonly with local invasion. May be associated with maldeveloped testes or adenomatous hyperplasia of the rete testis. Prognosis is poor, with ~10% survival at 5 yr. Malignant carcinoid include retroperitoneal lymph nodes, lungs, bone, and liver. The diagnostic criteria include:

- Tumor in mediastinum separate from the body of testis
- Transition in rete testis from normal gynadenium to neoplastic cells
- No evidence of teratoma
- No primary tumor elsewhere
- Intact pial arterial tumor

**TREATMENT**
- Radical orchectomy is the mainstay of treatment.
- XRT and chemotherapy have limited efficacy for metastatic disease.
- Retroperitoneal lymph node dissection may have a role in the absence of metastasis.

**REFERENCE**

---

**RETROCEVAL/CIRCUMCEVAL URETER**

**DESCRIPTION**
A rare congenital anomaly in which the intrapelvic ureters (IVU) are derived from the right subarcuate or preaortic vein, anterior to the vena cava. The term circumcaval ureter refers to the ureter emerging medial to IV, after running behind it. While the term retroceval applies to those ureters that only belong to the IV (but re-erune normally. Nodules are affected at times more often than are females. Not all retroceval/circumcaval ureters are obstructed, but if obstruction exists, surgical repair is typically warranted. CT is the best imaging modality for identification. Despite its congenital origin, symptoms are usually absent in childhood and present later in life. Less commonly, patients present with hematuria or UI.

**REFERENCE**

---

**RETROGRADE URETHROGRAM (RUG), TECHNIQUE**

**DESCRIPTION**
RUG is used to radiographically evaluate the urethra. It is most commonly used to evaluate urethral stricture disease or trauma. It is commonly performed by inserting a Foley catheter or Broden’s clamp into the Fossa Navicularis. The balloon is inflated with a few milliliters of water to create a seal. Then 50 cc of contrast solution is injected into the urethra under low pressures while obtaining a series of x-rays. An oblique view allows best visualization of the entire urethra (Image 1).

**REFERENCE**

---

**RETROPERITONEAL NEPHROMATOSIS**

**DESCRIPTION**
A retroperitoneal hematoma is hemorrhage contained within the retroperitoneum. Etiologies include disruption of the kidney or renal pedicle from trauma, postoperative hemorrhage, spontaneous hemorrhage of a renal mass typically angiomylipoma (or RCC), or abdominopelvic visceral hemorrhage. Echocardiomy may be observed around the umbilicus (Lumen sign) or flank (Loin-Turner sign). Management is primarily conservative, including frequent hemoglobin levels, resuscitation, and transfusion, as necessary. However, if the patient is hemodynamically unstable and the bleeding is from a renal source, and they have an expanding pelvic hematoma, or renal hematoma cannot be stopped with selective embolization, then surgical exploration is indicated. Further evaluation of the underlying pathology and follow-up imaging for resolution is warranted. (See also Section I. Renal Angiomyolipoma; “Retroperitoneal Abcess,” “Retroperitoneal Masses and Cysts,” and Image 2.)

**REFERENCE**

---

**RETROPERITONEAL LIPOSARCOMA**

**DESCRIPTION**
Retroperitoneal liposarcoma is the most common retroperitoneal sarcoma arising from adipose tissue. However retroperitoneal sarcomas are rare, with just 2-3 new cases per 1 million persons reported annually. They are usually identified incidentally or at a locally advanced stage when they cause symptoms from adjacent tissue invasion or compression. Compression of ureters can cause obstructive uropathy. Metastatic disease includes bone, lung, skin, and liver. If the mass is visualized on CT or MRI, abdominal mass containing variable amount of fat (<20 Hounsfield units) and soft tissue components. A germ cell tumor (GCT) must be ruled out by tumor markers, and a biopsy is necessary if there is diagnostic uncertainty. Complete resection is the only curative treatment. Radiotherapy can be used preoperatively for local control. (See also Section I. “Retroperitoneal Masses and Cysts,” and Image 2.)

**REFERENCE**

---

**RETROPERITONEAL LIPOMATOSIS**

**DESCRIPTION**
Lymphoma involving retroperitoneal lymph nodes: it can be the primary site of involvement or a site of metastasis. The lesion can cause extrinsic compression of ureters with obstructive uropathy. Positive diagnosis is made when a mass is visualized on CT or MRI. Differential diagnosis may include retroperitoneal fibrosis, retroperitoneal fat necrosis, lipoblastoma, sarcocoma, metastasis from other tumors such as prostate, or bladder or germ cell tumor metastasis. (See also Section I. “Retroperitoneal Masses and Cysts,” and Image 2.)

**TREATMENT**
- CHOP chemotherapy (cyclophosphamide, Adriamycin, vincristine, prednisone) and radiation therapy
- Obstructive uropathy may require ureteral stenting or percutaneous decompression prior to chemotherapy

**REFERENCE**

---

**RETROPERITONEAL RHEUMATOID NODULES**

**DESCRIPTION**
Rheumatoid nodules (necrobiotic granulomas) are a common extra-articular manifestation of rheumatoid arthritis, usually found in subcutaneous tissue. They have been reported in numerous other locations, including blood vessels, skin, eye, and extraspinal space. GU involvement is rare and can include renal tumor and bladder. Retroperitoneal occurrence has been reported and can cause extrinsic compression or obstruction requiring ureterolysis and repair. (See also Section I. “Retroperitoneal Masses and Cysts.”)
The most lethal renal neoplasm, Ewing’s sarcoma, comprises 2% of all renal tumors and primarily affects children under the age of 15. The incidence has increased from 1976 to 1996, Volume 3, Journal of Cancer Control.

**RETROPERITONEAL SARCMA**

DESCRIPTION Retroperitoneal sarcomas are mesenchymal neoplasms. Approximately 1/2 of retroperitoneal sarcomas are high-grade tumors, with the most common type being liposarcoma, followed by leiomyosarcoma. Median age at presentation is 50, although they can occur at any age. At the time of diagnosis, more than 50% are ≥ 2 cm in size. They are typically incidentally diagnosed but when patients do present with symptoms they are abdominal or back pain and increased abdominal girth. Differential diagnosis of a retroperitoneal mass includes neoplasm from a retroperitoneal viscerial structure, lymphoma, or a metastatic lesion. Retroperitoneal sarcomas carry a worse prognosis than extrarenal sarcomas due to the difficulty of complete resection, involvement of critical structures, and delay of diagnosis. CT is the imaging modality of choice. In patients with systemic therapy; or radiation therapy should be based on optimizing the patient for surgical resection. (See also Section 1: "Retroperitoneal Masses and Cysts.)" REFERENCES Mullins R, Zager JS, Gonzalez RJ. Current diagnosis and management of retroperitoneal sarcoma. Cancer Control. 2011;18(3):177–187.

**RETROPERITONEAL FAT NECROSIS**

DESCRIPTION Retroperitoneal fat necrosis is a pathology syndrome characterized by the histologic hallmarks of coalescence of fat cells into fat cysts bordered by foreign body giant cell granulomas. Local injury to fat cells from trauma appears to be the initiating event of fat necrosis in the retroperitoneum. In addition, an inflammatory trigger such as acute pancreatitis can result in the inflammatory syndrome. In patients with systemic therapy; or radiation therapy should be based on optimizing the patient for surgical resection. (See also Section 1: "Retroperitoneal Masses and Cysts.)" REFERENCES Ross JS, Plotz MR. Retroperitoneal fat necrosis producing severe obstruction. J Urol. 1974;113(5):524–529.

**RHABDOMYOID TUMOR, MALIGNANT**

DESCRIPTION The most lethal renal neoplasm, termed a “tumor of Wilms,” is comprised of 2% of all renal tumors and primarily affects children under the age of 15. The incidence has increased from 0.1 per million in 1986 to 1.4 per million in 2005. It has a tendency to early metastatic spread. The most common presentation is an abdominal mass detected in these young patients. Extrarenal sites include central nervous system (35%), liver, and gastrointestinal tract. Presence of mutations in the HOX11 gene on chromosome 12 is the hallmark. The lack of staining of the RKI gene product is diagnostic. Younger patients have a worse prognosis compared with older patients. Radiation therapy is an essential part of multimodality therapy. REFERENCES Zhuge Y, Cheung MC, Yang R, et al. Pediatric rhabdomyosarcoma: update on etiology, pathology, and management of rhabdomyosarcoma. J Surg Res. 2010;163(2):257–269.

**RIEGER SYNDROME**

DESCRIPTION Also known as the Axenfeld-Rieger Syndrome, this is an autosomal dominant syndrome affecting multiple organ systems. It is manifested by ocular anomalies such as glaucoma, cardiovascular defects, and malformations of craniofacial structures, which can result in severe endodermal stenosis. Genitourinary anomalies occur in the form of hypoplasia. In most cases, there has been identified as FTOX2 and FOXC1 on chromosome 25. REFERENCES Chang HC, Simmons CG, Schimmenti LA, et al. Axenfeld-Rieger syndrome: new perspectives. Br J Ophthalmol. 2012;96(3):318–322.

**RIFLE CRITERION FOR ACUTE RENAL INJURY**

DESCRIPTION Also referred to as the RIFLE Classification system for AKI, it assesses levels of renal injury (Risk, Injury, and Failure) based on the degree of elevation in serum creatinine or urine output, and 2 outcome measures (Loss and End stage renal disease):• Risk: 1.5× increase in creatinine or 25% GFR decrease by 25% or urine output <0.5 mL/kg/h for 6 hr• Injury: 2× increase in creatinine or 50% GFR decrease or urine output <0.5 mL/kg/h for 12 hr• Failure: 3× increase in creatinine or 75% GFR decrease or urine output <0.25 mL/kg/h for 12 hr or urine output <0.5 mL/kg/h for 4 hr or anuria for 12 hr• Loss: Complete loss of kidney function (eg, renal replacement therapy necessary) for >4 wk• End stage renal disease (ESRD): Complete loss of kidney function (eg, renal replacement therapy necessary) for >3 moThe RIFLE criteria correlate with prognosis, with a stepwise increase in the risk of death in patients who meet the RIFLE criteria for various stages of AKI. Compared to patients without AKI, patients in the RIFLE stages of risk, injury, and failure had increased mortality risks of 2.4, 4.13, and 6.37, respectively. (See also Section 1: “Acute Kidney Injury, Adrenal (Renal Failure, Acute)."

**RIM SIGN (RIM NEPHROGRAM)**

**ROBINOW SYNDROME**

DESCRIPTION A skeletal dysplasia with both autosomal dominant and recessive inheritance pattern. It is characterized by short stature, limbs shortening, genital hypoplasia (micropenis), and craniofacial abnormalities. The more phenotypically severe autosomal recessive form has been associated with mutations in the ROR2 gene on the long arm of chromosome 10. REFERENCES Penson AD, Beiraghi S, Sieben CM, et al. WNT3A mutations in patients with autolosomal dominant Robinow syndrome. Dev Dyn. 2010;239(1):327–337.

**ROBSON STAGING SYSTEM**

DESCRIPTION Robson’s modification of Flocks and Kadow’s staging system for renal cell carcinoma (RCC) was the most commonly used in the United States. The fact that long-term evaluation of patients with stage IIIA lesions, without disease extension into perinephric fat and lymph nodes, has shown survival comparable to those at stage II and III, has currently led many investigators to prefer the TNM system proposed by UICC. (See Section 2: “Renal Cell Carcinoma, General”; Section VII: “Tumors.”) Stage I: Tumor is confined within the kidney parenchyma (no involvement of perinephric fat, renal vein, or regional nodes). Stage II: Tumor involves the perinephric fat but is confined within Gerota fascia (including adrenal). Stage III: Tumor involves the renal vein or inferior vena cava. Stage IV: Tumor involves regional lymph nodes. Stage IVB: Tumor involves both local vessels and regional lymph nodes. Stage IVc: Tumor involves adjacent organs other than the adrenals (colon, pancreas, etc.). Stage IVf: Distant metastases. REFERENCES Robson CJ, Churchill BM, Anderson W. The results of radical nephrectomy for renal cell carcinoma. Trans Am Assoc Genitourin Surg. 1968;90:122–129.
ROKITSKY–KUSTER–HAUSER SYNDROME

DESCRIPTION Pathologic condition characterized by the presence of ovaries and infertility and by a congenital aplasia of the uterus and upper 2/3 of the vagina. Also referred to in the literature as Mayer–Rokitansky–Kuster–Hauser Syndrome. The condition is usually discovered during evaluation of a normal-appearing girl who presents with failure of menstruation at the time of expected puberty. They have a normal female karyotype 46, XX and do not develop normal secondary sexual characteristics. The syndrome may be caused by the lack of development of the Müllerian ducts between the 5th and 6th wk of gestation. In some patients, cyclic abdominal pain suggestive of some functional endometriosis is noted. Vaginal reconstruction with bowel or skin grafting is performed. It can also be associated with renal and skeletal abnormalities.

ROSEWATER SYNDROME

DESCRIPTION Rosewater syndrome is an infertility disorder associated with germ cell aplasia. On histologic biopsy, the seminiferous tubules contain only Sertoli cells. This is considered irreversible and precludes germ cell restoration. Not infrequently, tubular and peritubular fibrosis is associated with germ cell aplasia.

ROVING POLYCYSTIC KIDNEY OPERATION

DESCRIPTION A historically important surgical procedure that entails unroofing multiple renal cysts. The procedure of implantation occurs in usually 2 stages. Stage I consists of percutaneous placement of temporary wire leads into the 53 tumor. It can either be performed in the office or in the operating room. A 1–2 wk trial period occurs with the leads in place and voiding symptoms are monitored. If >50% improvement in symptoms occur, the patient moves on to Stage II which is always performed in the operating room. Permanent leads are placed as well an implantable pulse generator. The most commonly used device is the implantable® (Medtronic, Minneapolis, Minnesota) (FDA-approved since 1997 for urge incontinence and since 1999 for urinary retention and significant symptoms of urge-frequency) (Stage I).

SANI SCORE

DESCRIPTION The Sani Score (Survival after Nephrectomy and Immunotherapy) score is a tool for predicting survival for patients with metastatic RCC in response to the multimodality treatment of aggressive surgical resection and systemic immunotherapy. The regional lymph node status, the presence or absence of constitutional symptoms, the location of metastases, the presence or absence of sarcomatoid pathologic features, and TSH levels are incorporated into the scoring algorithm. Patients are stratified based on predicted survival into low-risk, intermediate-risk, and high-risk groups for appropriate treatment regimens and for prospective trials of new therapies.

SCABIES, UROLOGIC CONSIDERATIONS

DESCRIPTION An intensely pruritic parasitic infection that affects superficial areas of the body, including the genitalia, anus, legs, hands, umbilicus, and axilla. Diagnosis can be made by identifying the mite (Sarcoptes scabiei), expressed from the papular (FDA-approved since 1997 for urge incontinence and decrease in available sex hormone-binding globulin) or papule. In females, the presence or absence of sarcomatoid pathologic features, and TSH levels are incorporated into the scoring algorithm. Patients are stratified based on predicted survival into low-risk, intermediate-risk, and high-risk groups for appropriate treatment regimens and for prospective trials of new therapies.

SCROTAL SKIN LESIONS

SCROMISTOSOMIASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION A parasitic infection by the blood fluke Schistosoma haematobium. This condition has a broad spectrum of urologic manifestations due to the parasite’s life cycle. Infection across the skin-hematuria migration to pelvis/vesical venous plexus, transmural migration into bladder, and shedding into urine. Typically, patients will exhibit polypoid urethral mucosal lesions (active infection) or “sandy patch” flat, tan lesions (inactive infectious). Significant upper urinary tract obstruction is possible with chronic disease. Classic symptoms are hematuria and terminal dysuria. Infection has been linked to bladder cancer, occurring earlier in life (40–50 yr); this is most common squamous cell carcinoma (SCC) (80–90%) and adenocarcinoma (5–15%). The presence of fluke eggs in urinary sediment is diagnostic of schistosomiasis. (See also Section 1: “Bladder Cancer, Squamous Cell Carcinoma” and Image 90.)

TREATMENT

Medical management: Metrifonate and praziquantel

SCHWANNOMA, RENAL

DESCRIPTION Also called neurinoma or neurolemmoma, a tumor arising from Schwann cell neural elements of the kidney. Schwannomas of renal origin are very rare with only 20 reported cases in the literature. They present in middle-aged patients with a male-to-female ratio of 2:1. They typically appear as spherical, solid, and well-circumscribed encapsulated lesions. The vast majority are benign, and the malignant degeneration is very rare. Partial or radical nephrectomy (open or laparoscopic technique) is the treatment of choice as there are no reliable preoperative diagnostic methods.

REFERENCES

SCROTAL PEARLS (SCRUTOLITHS)

DESCRIPTION Benign calcifications within the scrotum, usually non-fungating. Usually diagnosed by ultrasound, these are described as a hypoechoic density in the scrotal wall that demonstrates acoustic shadowing. Scrotal pearls can occur from infection or trauma and themselves are rarely symptomatic. They may also be noted as artifacts after torsion of the scrotum.

REFERENCES

SCROTAL SKIN LESIONS

DESCRIPTION Scrotal skin lesions may be localized or a manifestation of more systemic diseases.

- Benign
  - Amyloidosis (rare)
  - Angiokeratoma of Fordyce: Small, 1–2 mm red, vascular elevations seen predominantly in male non-smokers
  - Atopic dermatitis: Involves the scrotum or scratch cycle with lichenification with or without excoriation. The posterior scrotum is a common site.
- Calcinosis, idiopathic scrotal
SCROTAL TONGUE

- Contact dermatitis: Allergic or irritant. Pruritus, burning, and itching.
- Eczema: frequently affects the genital region, particularly the scrotum. Patients present with intense, itchy, erythematous plaques on the lateral scrotum. The eruption may develop into Lichen simplex chronicus (LSC) (also referred to as “Neurodermatitis”) characterized by extensive lichenification and hyper trophy of the affected skin due to excessive scratching and rubbing.
- Epithelioid hemangioendothelioma, penis, and scrotum
- Fixed drug eruption: Erythematous, well-demarcated “bump-like” area, may evolve from erythema to vesicles or blisters.
- Folliculitis: Usually caused by Staphylococcus aureus.
- Gential lichen: Hyperpigmented macules that may be confused with melanoma.
- Gental warts (condyloma): Uncommon on the scrotum
- Ichthyosis: excessive amounts of dry surface scales; inherited or acquired.
- Insect bite
- Kaposi sarcoma: A purple, papular, plaque-like, or ulcerated lesion.
- Lichen simplex chronicus (LSC): Reaction to irritants, particularly the scrotum. Patients present with lichenified erythematous plaques on the lateral scrotum, which drain the testis that can be palpated through the scrotal skin. Overall, they are present in 15% of the male population. Varicocele is the most common etiology of male factor infertility, being present in 35% of males with primary infertility and 81% with secondary infertility. They most commonly occur on the left scrotum and the testis. If the gonad is dysplastic and associated with other GU anomalies (upper tract), this is termed scrotal tongue, with the condition representing a spectrum of penoscrotal transposition abnormalities. Surgical repair is recommended management. (See Section II: “Scrotum, Engulfment (Penscrotal Transposition),” and Image 6).

REFERENCES

SCROTAL TONGUE

DESCRIPTION

Scrotal tongue is not a urticarial condition. It refers to a deeply fissured tongue.

TREATMENT

- If the varicocele is not associated with infertility, decreases testicular volume or pain, it is considered subclinical and surgical correction is not indicated.
- The scrotum is repositioned around the scrotal skin and the base of the penis. This allows placement of the scrotal flaps beneath the penis. Malignant tumors may evolve into the scrotal skin and the testis. If the gonad is dysplastic and associated with other GU anomalies (upper tract), this is termed scrotal tongue, with the condition representing a spectrum of penoscrotal transposition abnormalities. Surgical repair is recommended management. (See Section II: “Scrotum, Engulfment (Penscrotal Transposition),” and Image 6).

REFERENCES

SCROTUM, EPIDERMAL INCLUSION CYST

DESCRIPTION

Epidemidial inclusion cysts are benign tumors. They result from the implantation of epidermal tissue into the dermis or subcutis, from trauma or abnormal embryologic closure of the median raphe and urethral groove. These lesions appear solid on imaging and often contain a material that is a combination of keratin and cholesterol, often in a laminated configuration arising from a straddled squamous epithelial wall. They can be asymptomatic or more commonly rupture or become infected. Local excision is the treatment, since epidemidial inclusion cysts can mimic rare malignant
tumors such as liposarcoma, fibrosarcoma, and even metastatic disease.

REFERENCE

SCROTUM, FAT NECROSIS
DESCRIPTION
An uncommon lesion that is seen in prepubertal boys and can be a cause of acute scrotal pain. Typical presentation is an obese prepubertal child with recent exposure to cold, such as during swimming. Bilateral intrascrotal masses are present inferior to the testes. If the diagnosis is made with US and shows the classic presentation, conservative management can be employed.

REFERENCE

SCROTUM, GIANT NEUROLEMMOMA
DESCRIPTION
Well-encapsulated tumors of neural elements (also called neurinoma or Schwannoma) within the scrotum. Most such tumors are benign, with malignant transformation as an extremely rare occurrence. Surgical removal of the lesion is the definitive treatment.

REFERENCE

SCROTUM, HEMANGIOMA
DESCRIPTION
These lesions should be differentiated from angiokarstoma of Fournier that appear in older men (see Section II). “Angiokarstoma of Fournier (Perineal and Scrotal Angiokarstoma)” Hemangiomas represent 7% of all nonmalignant tumors and are the most common benign tumor of infancy; however, they invade the penis and scrotum only 1% of the time. Cutaneous hemangiomas also called (strawberry angiomas) are the most common benign tumor of infancy and are usually present at birth. Although such skin lesions are usually painless, they may cause functional impairment in infants. Laser therapy is necessary unless recurrent episodes of infection occur; then surgical excision may help.

REFERENCE

SEAPI INCONTINENCE CLASSIFICATION SYSTEM
DESCRIPTION
SEAPI is an acronym for stress incontinence, emptying ability, anxiety, protection, and instability. It is a useful and uniform method of following the short- and long-term outcome of stress urinary incontinence (SUI) surgery. This system is similar to the TNM tumor staging classification system in that each component is graded on a scale from 0 to 3 (normal to severe symptoms). After completion of the evaluation of the incontinent patient, a prospective subjective and objective SEAPI score is determined. These scores are then compared with postoperative SEAPI scores to assess treatment outcomes. It has been found to have a high degree of reliability and internal consistency across a wide age range in both genders.

REFERENCE

SEBORRHEIC DERMATITIS
DESCRIPTION
Commonly referred to as dandruff, this condition can be seen on the penis, anus, or pubic hair. Pruritus is the rule, with the lesions in hair-bearing areas having a red base and scaly yellow crust. While the organism Pityrosporon orbiculare is suspected, the exact agent is unknown. Standard antifungal shampoos are usually effective. Shampoo containing ketoconazole may be needed. Steroids should be used with caution, if at all, because this tends to be a lifelong problem. (See also Section II: “Pruritus, External Genitalia, Male.”)

REFERENCE

SEMIN ANALYSIS, ABNORMAL FINDINGS AND TERMINOLOGY
REFERENCE
ABNORMAL FINDINGS AND TERMINOLOGY
A significant overlap exists between fertile, subfertile, and infertile populations; therefore, absolute parameters for infertility (easest for aspermia or azoospermia) are difficult to measure precisely. In general, fertile populations demonstrate mean sperm densities of 70–80 million/mL. Assisted reproduction techniques (ART) are now able to overcome many of these abnormalities. (See also Section I: “Infertility.” Section II: “Semen Analysis, Technique, and Normal Values.” and “Semen Analysis, Abnormal Findings and Terminology.”)

Aspermia: No semen ejaculated

Azoospermia: <150 spermatozoa with forward progression of 3 or 4

Hypospermia: Poor motility and/or poor forward progression

Necrozoospermia: No live sperm in ejaculated semen

Normozoospermia(Men): Refer to a normal semen analysis

Oligoasthenospermia: Very generalized abnormalities in sperm concentration, motility, and morphology; often associated with varicocele

Oligocentrozoospermia: Significant disturbance of all 3 variables (combinations of 2 profiles may also be used)

Oligozoospermia: Low concentration of sperm (500,000–1 million/mL)

Polyospermia: Abnormally high density sperm >250 x 10^6/mL

Polyospermia: Excess number of sperm in ejaculate sample

Pycnosis/leukocytes: Excess white cells >1 white cell = 10^6/mL in semen

Teratozoospermia: Reduced percentage of morphologically normal sperm, usually <10% spermatozoa with normal morphology

REFERENCES

871
SEMEN ANALYSIS, TECHNIQUE, NORMAL VALUES

DESCRIPTION: Normozoospermia/normospermia are terms sometimes used to refer to a normal semen analysis. After 48–72 hr of abstinence, a semen specimen is collected in a wide-mouth polypropylene container with a screw top through masturbation without the use of any lubricants that could contaminate the sample. Care must be taken to capture all of the ejaculate. The sample is kept at close to body temperature as possible and delivered to the lab within 1.5 hr. Analysis includes (may vary slightly by lab) total seminal volume, sperm concentration, sperm mobility, sperm morphology, fructose content, coagulation time, liquefaction time, viscosity, and leukocyte count. Newer computer-assisted systems (CASA) can also evaluate curvilinear velocity, straight-line velocity, linearity, and amplitude of lateral head displacement. Antisperm antibodies may be considered a secondary test. Normal parameters are established by most labs. The following are general reference parameters and are typically determined on at least 2 specimens. (See also Section II: "Infertility"); and Section II: "Semen Analysis, Abnormal"; also see Section II for topics on specific semen abnormalities.

SEMEN LEUKOCYTES

DESCRIPTION: The leukocyte is the most common nonsemen cell seen in a semen analysis, and it may be confused with immature spermatozoa on microscopy. Leukocytospermia and pyospermia are terms used to describe excess white cells in the semen specimen (> 10³/mL). Elevations usually are associated with infection, but may be linked to reactive oxygen species and may be present when there is no finding of infection or immune response. Leukocytospermia is often found in patients with unexplained infertility. Semen cultures are prone to contamination, and the use of antibiotics to treat pyospermia is controversial. (See also Section II: "Infertility"; Section II: "Semen Analysis, Abnormal Findings and Terminology"); "Semen Analysis, Technique, Normal Values"; and "Pyospermia.""

SEMEN PLASMA HYPERSENSITIVITY (SEMINAL PLASMA ALLERGY) AND HYPERSENSITIVITY TO HUMAN SEMEN (HHS)

DESCRIPTION: An allergic reaction to human semen that presents as a systemic reaction (ranging from mild to anaphylaxis) in a localized vaginal symptoms shortly after ejaculation into the vagina. Two types described in the literature the more common reaction to human seminal plasma (allergic reactions to human seminal plasma [HSP] proteins) or a response to spermatozoa (hyperreactivity to human semen [HHS]). These conditions are likely underestimated and may not be discussed or accepted in-gynecology or urology. These are seen exclusively in women (usually from 20–30 yr of age) and can be avoided through the use of condoms or less commonly through anti-allergy medications or allergen desensitization. Once established, it usually occurs with other male partners. In addition to the potential symptoms infertility is an issue.

SEMINAL VESICLE AGENESIS

DESCRIPTION: Can be unilateral or bilateral (very rare). Unilateral agenesis results from an embryologic insult before separation of the seminal bud from the mesonephric ducts. Unilateral agenesis is associated with (possibility) agenesis of the ductus deferens and with renal agenesis in 79%, (possibility) renal abnormalities in 12%, and only 8% had normal kidney bilaterally. The contralateral seminal vesicle is often hypoplastic.

SEMENAL VESICLE CALCULI AND CALCIFICATIONS

DESCRIPTION: Calcium of via deferens seems to be specific to diabetes mellitus and may be associated with calcification of the seminal vesicles. Other causes include TB, chlamydia, gonorrhea, and ureaplasma with secondary hyperparathyroidism. Intraluminal seminal vesicle calculation can be seen (Image 42).

SEMENAL VESICLE, CARCINOMA

DESCRIPTION: Primary tumors of the seminal vesicles extremely rare as there are no more than 60 historically confirmed reported cases. The seminal vesicles are often secondarily involved by cancer of surrounding structures such as prostate, bladder, or rectal carcinoma. Lymphoma of the seminal vesicles has been reported. Primary adenocarcinoma of the seminal vesicle (the most common primary type) occurs in patients ~ 50. Immunohistochemistry is helpful in diagnosis. They are PSA and PSAP negative. RF and/or cyclosporine treatment including pelvic lymph node dissection, offers curative treatment. Adjacent or neoadjuvant chemotherapy is of unproven worth, but a combination of hormonal deprivation and radiation therapy seems to be more effective than any chemotherapy.

kidney bilaterally.
SEMINAL VESICLE, CYSTS

DESCRIPTION
Cysts, of either congenital or acquired origin, located in the seminal vesicles. Many studies in the past have linked cysts to other GU issues, including renal agenesis, infertility, hematopoeisia, GU infection, and adult polycystic kidney disease. Cysts are congenital, ejaculatory duct obstruction (EDO), or a basement membrane defect, especially associated with adult polycystic kidney disease. (See also Section I: “Seminal Vesicle Masses and Cysts” and Image 2D)

TREATMENT
• No treatment is necessary if asymptomatic.
• Aquisation, manipulation, or excision, if symptomatic

REFERENCE

SEMINAL VESICULITIS

DESCRIPTION
Inflammation of the seminal vesicles that often occurs secondary to bacterial infection, causing prostatitis or epididymitis. Older literature referred to this condition as pyospermia. Symptoms are often vague and may include pain, scrotal, or perineal, painful ejaculation, hematopoeisia, lower abdominal or back pain; and LUTS. Diagnosis is often 1 of exclusion of other more common causes made with positive cultures from the ejaculate as well as imaging via transrectal US, CT, or MR. Pyospermia/leukocysteorrhea is prominent on semen analysis. Abscess formation is a complication of seminal vesiculitis and can be an initial presentation of the disease. Treatment includes culture-sensitive antibiotics, transrectal aspiration, or excision (open or laparoscopic seminal vesiculectomy) for severe cases. Tumoral seminal vesiculocystic with irrigation has been described. (See also Section II: “Pyospermia.”)

REFERENCES

SEXUAL ANHEDONIA/EJACULATORY ANHEDONIA

SEMINALOMA, CLASSIC

DESCRIPTION
The most common histologic subtype of seminomatous germ cell tumor (GCT). It accounts for ~80% of cases. Typically presents in males in the 30–50th decades of life. Syncytiotrophoblastic elements are seen in 10% of cases. These elements produce δ-hCG, which can be used as a tumor marker to help assesses prognosis or recurrence of disease after treatment. Unlike all other testicular tumors, treatment depends on tumor stage. Radical orchectomy followed by either surveillance, radiation therapy, and/or chemotherapy are performed, depending on the extent of disease. (See also Section I: “Testis, Seminoma.”)

REFERENCE

SEMINOMA, SPERMATOCYTIC

DESCRIPTION
Accounts for ~2% of all seminomatous germ cell tumor (GCT). Patients present later in life, usually in their 5th–6th decades. Unlike classic and anaplastic subtypes, spermatocytic seminoma rarely metastasizes. It is believed that this subtype arises from a different, more mature germ cell, which likely contributes to its more favorable presentation. Due to its low metastatic potential, no further treatment is often recommended after radical orchectomy. (See also Section I: “Testis, Seminoma.”)

REFERENCE

SEX REVERSAL SYNDROME (XX MALE)

DESCRIPTION
These patients demonstrate small, firm testes. Frequent gynaecomastia, a small to normal penis, and azoospermia. Testicular biopsy may demonstrate seminiferous tubuli scarring, causing elevated gonadotropins and decreased testosterone levels. Individuals are shorter than average height.

TREATMENT
• No treatment is necessary if asymptomatic.
• Further treatment is often recommended after radical orchectomy. (See also Section I: “Testis, Seminoma.”)

REFERENCE

REFERENCES

SEX-HORMONE BINDING GLOBULIN (SHBG)

DEFINITION
Testosterone (T) circulates bound to either SHBG, albumin (A), or sex-hormone binding globulin (SBG), or in an unbound form (free). SHBG-bound T is about 44% of the total T and is unavailable to cells. Albumin-bound T is about 50% of the total. Conditions that increase SHBG, include aging, hyperthyroidism, estrogen, HIV disease, anticonvulsants, heparin and heparin citrate. Conditions that decrease SHBG, include obesity, diabetes mellitus, hyperthyroidism, androgentic steroids, nephrotic syndrome, anorexia and glucocorticoids. The age-related SHBG increase means that older men may have a normal T-levels even if they are hypogonadal, as they will have low levels of free or bioavailable T. Obesity, on the other hand, decreases SHBG and T, even when the available T may be normal.

REFERENCE

SEXSOMNIA

DESCRIPTION
Sексsomnia, also known as somnambulistic sexual behavior or sleep sex is a particular form of parasomnia (disruptive sleep disorder) characterized by atypical sexual behavior during sleep. The repetition of sexual behavior during sleep can vary from explicit vocalizations with sexual content, violent masturbation, and complex sexual activities including oral sex, vaginal or anal intercourse. The exact etiology is unknown, but precipitating factors are stress, sleep deprivation/fragmentation, alcohol or drug consumption, excessive fatigue and physical overactivity in the evening.

TREATMENT
• Medications such as benzodiazepines are 1st-line therapy.
• Sleep hygiene and safety precautions should be implemented.

REFERENCE

SEXUAL ANHEDONIA/ EJACULATORY ANHEDONIA

DESCRIPTION
Lack of appropriate pleasure from sexual activity. Patients typically report a failure of genital response. Men have difficulty initiating or sustaining an erection, pre-menopausal women have difficulty with lubrication. Ejaculatory anhedonia describes lack of pleasure during ejaculation. Although a psychogenic etiology is often present, the clinician must rule-out hormonal influences. Medications such as...
SEXUAL FUNCTION SURVEY (SFS) (INTERNATIONAL INDEX OF ERECTILE FUNCTION (IIEF))

DESCRIPTION: The IIEF is a 15-item, self-administered questionnaire scale for the assessment of erectile function that has been linguistically validated in 10 languages. It addresses the relevant domains of male sexual function: erectile function (EF), organic function (OF), sexual desire (SD), intercourse satisfaction (IS), and overall satisfaction. EF is represented in items 1 and 5 of the questionnaire, with a score range of 0–5, a minimum score of 0, and a maximum score of 30. IS is represented in items 9 and 10, with a score range of 0–5, a minimum score of 0, and a maximum score of 30. SD is represented in items 1 and 2, with a score range of 0–6, a minimum score of 0, and a maximum score of 30. EF, IS, and SD are each represented in 1 item of the questionnaire, with a score range of 0–15, a minimum score of 0, and a maximum score of 45. The questionnaire consists of 5 questions pertaining to the relevant domains of male sexual function: Erectile Function [IIEF] [Sexual Function Survey]."

REFERENCES

An extremely rare primary urethral malignancy that may become infected and present as a tender, fluctuant perineal nodule. Infection or inflammation of the Skene glands can cause exquisite tenderness and may be associated with dyspareunia and vulvar vestibulitis. The most common pathogens is Klebsiella pneumoniae. Treatment includes cultures of infected area along with surgical incision and drainage if abscess formation is present. Appropriate antibiotic therapy is administered. Other causes of vestibulitis or vulvodynia should be assessed and evaluated.

SKIN TAGS, EXTERNAL GENITALIA (ACROCHORDON, PEDUNCULATED PAPILLOMA, VESTIBULITIS)

DESCRIPTION: Benign, flesh-colored, soft pedunculated benign lesions that may occur anywhere on the body and generally are < 5 mm, although larger lesions can be seen. They may be pinkish, skin-colored, or hypopigmented and are more common on obese individuals. Usually asymptomatic, these lesions are often found in skin folds (neck, armpit, and labia), and rarely involve the external genitalia. They may accompany hamartomatous skin lesions in tuberous sclerosis complex or neurofibromatosis. Birt–Hogg–Dubé syndrome. Irritation and possibly HPV types 6/11 are possible causes. No treatment is necessary, and they are usually considered clinically insignificant. If treatment is desired for cosmetic reasons, then the tags may be treated by electrocautery, simple incision or excision, suture ligation of the base, or cryotherapy.

REFERENCES

SLEEP APNEA, UROLOGIC CONSIDERATIONS

DESCRIPTION: Patients with obstructive sleep apnea may have their condition exacerbated by testosterone replacement therapy (TRT), their sleep apnea status should be monitored closely and treated if possible. Sleep apnea also may cause nocturnal hypoxia and may be a factor for erectile dysfunction (ED). Obstructive sleep apnea may also be involved with nocturnal and daytime erectile bladders in women.

REFERENCES

SHY DRAGER SYNDROME, UROLOGIC CONSIDERATIONS

DESCRIPTION: Shy Drager syndrome, also known as multiple system atrophy, is a progressive neurodegenerative disease in which the etiology is unknown. Bladder dysfunction causing urinary incontinence and erectile dysfunction (ED) are early features. Urinary urgency, frequency, incomplete bladder emptying as well as urinary retention or any combination are seen as urologic manifestations of the Shy Drager syndrome. In addition, weakness of the strained urethral sphincter contributes to incontinence. DO is seen on urodynamic evaluation.

Bladder dysfunction causing urinary incontinence and erectile dysfunction (ED) are early features. Urinary urgency, frequency, incomplete bladder emptying as well as urinary retention or any combination are seen as urologic manifestations of the Shy Drager syndrome. In addition, weakness of the strained urethral sphincter contributes to incontinence. DO is seen on urodynamic evaluation.

SMELLY GLANDS
DESCRIPTION
Smells, usually mid-urethral, are a common complaint for the treatment of intrinsic sphincteric deficiency. Smell materials are either autologous, allografts, xenografts, or synthetic. (See also Section I: “Urology, Female.”)

REFERENCE

SMITH-LEMLI–OPITZ SYNDROME
DESCRIPTION
An autosomal recessive multisystemic disease found in newborns that present with hypospadias and cryptorchidism. Anomalies in other systems include perinatal asphyxia, mental retardation, syndactyly, renal abnormalities, and microcephaly. These patients have an inborn error of cholesterol (biosynthesis defect of 3-hydroxy-3-methylglutaryl-CoA reductase), which results in deficiency of cholesterol and elevation of 7-dehydrocholesterol, a cholesterol precursor. Patients can take cholesterol with or without bile acids.

REFERENCE

SMOKING, UROLOGIC CONSIDERATIONS
DESCRIPTION
Smoking is a modifiable behavioral risk factor with an array of impact on urologic disorders. The smoking population attributable risk of bladder cancer is 50% in men and 52% in women. The relative risk of developing both renal parenchymal cancer as well as upper tract carcinoma ranged in men from 27–37% and 10–24% in women. In addition, there is a dose-response relationship as the risk of developing RCC is increased in lifelong smokers who smoke >20 cigarettes a day compared those who smoke less. Smoking may cause irreversible damage to neuromuscular and uro-endothelial mechanisms of erectile function as though only 20% of the population are smokers, 40% of men with ED are currently smokers. Smoking has also been associated with increased risk of acquiring HIV and HPV (both high and low-risk strains). The semen parameters in men who smoke have been found to be significantly decreased, especially sperm motility.

REFERENCE

SNODGRASS HYPOSPADIAS REPAIR
DESCRIPTION
Snodgrass hypospadias repair, also known as the Snodgrass method, is the most commonly performed operation to repair distal hypospadias. The key step in the procedure is a midline incision of the urethral plate. The urethral plate is then tubularized beginning at the neomeatus, which results in a slight overhang. Because sperm is highly antigenic, the inflammatory reaction creates a granuloma, which is usually asymptomatic. Some studies have shown that men who undergo vasectomy reversal have higher success rates if they have a sperm granuloma at the vasectomy site. A mass in the scrotum, often tender postvasectomy, is diagnostic.

REFERENCE

SODIUM CYANIDE NITROPRUSSIDE TEST
DESCRIPTION
A qualitative test for cystine. The assay involves the conversion by cyanide of cystine to cysteine and nitric oxide. Nitric oxide binds cysteine resulting in a purple color in 2–10 min. The test detects cystine levels above 75 mg/ml creatinine. If positive a quantitative 24-hr collection should be performed.

REFERENCE

SOLID TUMORS, RENAL
DESCRIPTION
Solitary fibrous tumors (SFTs) are mesenchymal tumors arising at any site. When involving the kidney, they arise from the capsule, renal pelvis, or hilar fatty tissue. They present similar to those with RCC. On gross appearance, the tumor is solid with a pseudocapsule. Microscopically, it shows a spindle cell proliferation. Controversy exists concerning the diagnosis of SFT and hemangiopericytoma because of overlapping immunohistochemical features. No cases of metastasis from renal SFTs has been described.

TREATMENT
Radical nephrectomy with complete excision including negative margins is needed for a favorable prognosis.

REFERENCE

SPERM GRANULOMA
DESCRIPTION
Sperm granulomas form from the injection of sperm into the scrotum and the vas deferens after vasectomy. Because sperm is highly antigenic, the inflammatory reaction creates a granuloma, which is usually asymptomatic. Some studies have shown that men who undergo vasectomy reversal have higher success rates if they have a sperm granuloma at the vasectomy site. A mass in the scrotum, often tender postvasectomy, is diagnostic.

TREATMENT
When chronic post-vasectomy pain is localized to the sperm granuloma, the lesion should be excised and occluded with electrocautery.

REFERENCES
Sperm Penetration Assay (Spa, Hamster Test)

REFERENCE

Sperm Penetration Assay (Spa, Hamster Test)

DESCRIPTION
Also called hamster ovocyte penetration assay test and in some publications (Hamster test), a test for infertility that assesses the ability of sperm to penetrate the ovum. The zona pellucida from hamster oocytes is removed, which allows capacitated human sperm to penetrate it. A test for sperm to be able to undergo capacitation, the acrosome reaction, fusion with the oocyte, and incorporation into the ooplasm. If sperm penetration is 10–30%, the sample is considered normal, but this estimation is not standardized. Some studies have shown that IVF success is correlated with a positive SPA, while others have not. These inconsistencies require that the physician become familiar with the lab performing this test. Although there are controversies surrounding SPA, it is a test that should be performed for unexplained infertility.

REFERENCE

Sperm Vitality

DESCRIPTION
Also referred to as sperm viability or sperm motility, this is 1 parameter in semen analysis during workup of male infertility. Determination of the percentage of viable and motile sperm in semen samples is helpful to determine if the sperm could be of therapeutic use for various fertilization techniques. (See also Section 1: “Infertility”, Section II: “Semen Analysis, Technique, and Normal Values.”)

REFERENCE

Spermatocord, Liposarcoma

DESCRIPTION
A low soft tissue malignancy derived from mesenchymal tissue. It is often mistaken for hydrocele, cord lipoma, or incarcerated hernia and preoperative diagnosis is rare. Most malignant paratesticular tumors are sarcomas, but 5–7% are liposarcomas. High-resolution ultrasound, CT, and MRI have become imaging of choice. Tumors in the literature have been reported to range from 0.4 cm to as large as 50 cm. The majority of tumors are low grade and well differentiated. Late recurrences and metastases may be seen, particularly with high-grade tumors. Radical orchidectomy with local excision and high ligation of the spermatocord is the treatment. Liposarcomas are radiosensitive and radiotherapy can be used to prevent local recurrence. The majority of tumors are low grade and well differentiated. The parallel tubular arrays have a spindle cell configuration. There are also rare case reports of spindle cell tumors involving the bladder and penis. The histologic features are characterized by elongated tubules and stromal changes. The stromal tumors are benign, although rare case reports of spindle cell neoplasms involving the bladder and penis. These neoplasms have been classified as leiomyosarcomas, which are benign. (See also Section 1: “Spermatocord and Torsion.”)

REFERENCE

Spina Bifida/Spina Bifida Occulta, Urologic Considerations

DESCRIPTION
Spina bifida is a brain defect that results in the incomplete closure of the embryologic neural tube, leading to incomplete development of the spinal cord and vertebral column. This usually involves the lumbar and sacral areas. As a result, many patients develop a neurogenic bladder dysfunction requiring long-term urogynecologic care. Although 90% of patients born with spina bifida have normal upper urinary tracts, over 1/3 of these patients will show signs of vesical dysfunction if no urologic intervention is performed. Spina bifida occulta is the milder form of spina bifida. The vertebrae may not fuse together, although the spinal cord and nerves are intact. Patients with spina bifida occulta may have no neurologic deficits at birth. Neurologic deficits that are present are usually mild compared to patients with spina bifida, and may develop later in life. Treatment involves appropriate urologic surveillance to preserve renal and bladder function. A neonatal renal US and voiding cystourethrography are obtained to assess for hydronephrosis and vesicoureteral reflux. Up to 20% of patients with spina bifida will have reflux. A urodynamics study (UDS) is also performed during this period to evaluate bladder compliance, detrusor pressures, capacity, leak pressures, contractions, and sphincter dysfunction. Some institutions recommend prophylactic antibiotics and CIU until the neonate’s 1st US. Patients with poorly compliant bladders with elevated filling pressures (typically above 40 cm H2O) are in danger of upper tract deterioration and are typically started on clean intermittent catheterization (CIC) and anticholinergic therapy. If the patient fails conservative medical therapy, surgical procedures such as intravesical bulking agent injection, vesicostomy, augmentation cystoplasty, or urinary diversion (continent or incontinent) may be appropriate treatment options. It should be stressed to patients and their families to have strict routine follow-up visits to evaluate bladder or upper tract deterioration. (See also Section 1: “Myelodysplasia Spinal Dysraphism, Urologic Considerations.” and Image D.)

REFERENCE

Spinal Cord Compression, Urologic Considerations

DESCRIPTION
Epidural spinal cord compression, due to a urologic etiology, is most likely bone metastasis from prostate cancer. Other types of cancer (eg, breast, lung, kidney, GI) must also be kept in mind. Venereal body metastases are present in the majority of patients dying from metastatic prostate cancer. Compression of the cord causes edema, venous congestion, and demyelination. Symptoms include back pain, progressive weakness, sensory loss, and paraparesis. Bowel and bladder dysfunction are late findings. Neurologic impairment can progress overnight, so patients must be followed carefully. Survival of patients with spinal cord compression due to metastasis is relatively poor. 40% of patients survive <6 mo, and 20–30% <2 mo. Diagnosis is based on findings of CT and MRI. (See also Section 1: “Spinal Cord Injury, Urologic Considerations.”)

REFERENCE

Spinal Shock

DESCRIPTION
After acute spinal cord injury (SCI), a period of areflexia and flaccid paralysis usually occurs below the level of injury. This period of spinal shock is variable; reflex detrusor activity usually returns after 2–12 wk, although it may take up to 1 yr. Urodynamic studies assessing bladder function are postponed until spinal shock resolve. Treatment is supportive during this period of detrusor areflexia. CIU is the recommended means of emptying the bladder, although an indwelling Foley catheter may be another alternative. (See also Section 1: “Spinal Cord Injury, Urologic Considerations.”)

REFERENCE

Spindle Cell Neoplasm, Urologic Considerations

DESCRIPTION
Mucinous tubular and spindle cell carcinoma (MUTC) is a rare neoplasm of the kidney and is distinct from the WHO as a variant of RCC. It is considered a low-grade carcinoma with a favorable prognosis. It typically presents in adult women in a 4:1 ratio. It is believed to be derived from the epithelial cells of the loop of Henle or possibly the collecting duct. There are also rare case reports of spindle cell neoplasm of the bladder and penis. The histologic features are characterized by elongated tubules and stromal arrangements, which are separated by mucinous stroma. The parallel tubular arrays have a spindle cell configuration. There are also rare case reports of spindle cell neoplasm involving the bladder and penis. These are considered low-grade carcinomas with a favorable prognosis. (See also Section 1: “Urologic Considerations.”)

STAMEY PROCEDURE (URETHROPEXY)

REFERENCE

SPINNING TOP URETHRA
DESCRIPTION Spinning top urethra (STU) is a widened posterior urethra seen mainly in girls that is seen on videourodynamic studies. The most common mechanism for dilatation of the posterior urethra is unstable bladder contractions are resisted by a voluntary increase in the tension of the external urethral sphincters. The increased pressure results in a dilatation of the posterior urethra. It is seen in patients with voiding dysfunction.

REFERENCE

SPLENIC INJURY DURING RADICAL NEPHRECTOMY
DESCRIPTION Of cases involving iatrogenic injury to the spleen, up to 12% have been reported to occur during nephrectomy. Splenic injuries usually tend to occur from excessive traction rather than direct injury or scalpel laceration; adequate exposure starting from an appropriate incision is essential. Capsular tears are the most common encountered event. The inferior portion of the spleen is typically involved, since the spleen has ligamentous associations (splenicocolic, splenorenal, splenophrenic) with the kidney and other nearby structures. The spleen has a rather loose texture and can be found crossing the upper pole of the left kidney, dividing into subcapsular branches. Optimal treatment first involves recognizing splenic injury in a timely fashion intraoperatively. Depending on the extent of injury and condition of the patient, the decision is made to proceed with either salvage of the spleen or splenectomy. Splenic salvage techniques depend on severity of injury and includes the use of topical hemostatic agents, primary suture repair, partial segmental resection, or mesh repair. Complications associated with splenic injury repair or splenectomy include subphrenic abscess, injury to the stomach, colon, or tail of the pancreas, pancreatic or pancreatico-facial fistula formation, and pleural effusion.

REFERENCE

SPLENOGONADAL FUSION
DESCRIPTION A rare congenital malformation in which an abnormal fusion exists between the spleen and the gonad or mesonephros derivatives. This fusion occurs in both sexes, but it is more common in males. Half of the cases are reported in children. The 2 types are continuous and discontinuous. In the continuous splenogonadal fusion, the main spleen is connected to the left hypogastric by a strand of tissue. This cord may be fibrous or splenic or contain beads of splenic tissue. The discontinuous type has no cord between the spleen and left gonad. 1/3 of all reported cases are associated with other congenital abnormalities, especially pernix. The majority of cases present with scrotal mass or scrotal tenderness. Some are found incidentally during herniorrhaphy or orchidectomy. Although evaluation is usually done in the operating room, a technetium99m colloid liver spleen scan can easily identify splenic tissue in the scrotum if splenogonadalfusion is suspected preoperatively. Scrotal US does not help to diagnose this entity.

TREATMENT
• Usually involves removing both the testis and adjoining mass.
• If the diagnosis of discontinuous splenogonadal fusion is made before surgery, the splenic nodule can simply be excised.
• For continuous variety, exploratory laparotomy is necessary to identify the anomaly involved and deal with the continuous cord.

REFERENCE

SPLENULES/SPLENOSIS, UROLOGIC CONSIDERATIONS
DESCRIPTION A benign condition associated with splenic rupture, typically during splenic surgery or trauma. Autotransplantation of splenic tissue occurs via seeding of spleen pulp in the abdominal or thoracic cavities. Hemangiomatous spread has also been reported. Patients are asymptomatic, and the discovery of splenules is usually incidentally on imaging studies. Splenosis in the abdominal cavity has been mistaken for primary malignancies, such as primary RCC. Similarly, thoracic splenosis can mimic metastatic uterine malignancies as well. The diagnostic modality of choice is nuclear scintigraphy. Once splenosis is confirmed and malignancy is ruled out, no treatment is necessary due to the benign nature of the condition.

REFERENCE

SPORTS HERNIA (ATHLETIC PUBALGIA, SPORTSMAN’S HERNIA)
DESCRIPTION A sports hernia is a painful, soft tissue injury that occurs in the groin area. It most often occurs during sports that require sudden changes of direction or intense twisting movements and is considered an "overuse" injury. It is a musculo-tendinous injury that involves the insertion of abdominal muscles on the pubis and the upper aponeurotic insertion of the adductor muscles. The pain develops during exercise, is generally unilateral but occasionally bilateral, and is typically located in the suprapubic and lower abdominal lateral to rectus abdominus, sometimes radiating to the testis. Although a sports hernia may lead to a traditional abdominal wall hernia, it is a different injury. A sports hernia is a strain or tear of any soft tissue (muscle, tendon, ligament) in the lower abdomen or groin area. Because different tissues may be affected and a traditional hernia may not exist, the medical community prefers the term athletic pubalgia to refer to this type of injury. The existence, significance and diagnosis of sports hernia are all controversial. The condition needs to be differentiated from a direct, indirect, or femoral groin hernia, adductor longus origin “tendinitis,” or obturator pain based on history and physical exam. The symptoms are nonspecific and can include tenderness on palpation of the medial inguinal floor, tenderness on palpation over the pubic rami, and exacerbated pain with resisted hip adduction. MRI may be useful in the differential. Rest, anti-inflammatory medications (NSAIDs) and physical therapy are beneficial. Rarely surgery may be necessary to repair the torn ligament or tendon.

REFERENCES

SQUAMOUS METAPLASIA, GENITOURINARY
DESCRIPTION The replacement of normal urothelium by metaplastic squamous epithelium. Nonkeratinizing squamous metaplasia is thought to be a normal variant in premalignant women, occurring under hormonal influence. This form is commonly seen in the ectocervix and, occasionally, it appears as a white patch. Keratinizing squamous metaplasia, also known as vesical leukoplakia, is a response to chronic irritation and infection. Some patients go on to develop squamous carcinoma. Keratinizing squamous metaplasia often occurs with long-term urinary catheterization, a bladder stone, vesical schistosomiasis; long-term observation is warranted for the development of squamous carcinoma of the bladder.

SYMPTOMS
• Pseudomembranous trigonitis
• Vesical leukoplakia

TREATMENT
Transurethral resection ablation and biopsy in cases of keratinizing squamous metaplasia.

REFERENCE

**STAMEY TEST (3-GLASS TEST, 4-GLASS TEST, MEARES–STAMEY TEST)***

**DESCRIPTION**

The 3-glass test described by Meares and Stamey is a method of collecting urine, which can provide information on the site of the urinary tract origin of RBCs or bacteria. Although this method is effective in the majority of cases of hematuria, it is more commonly used in diagnosing prostatitis. A specimen is collected from the urethra, midstream urine, and prostatic secretions. The 1st-voided 10 mL of urine is the urethral specimen (VB1). The midstream urine of 10 mL (VB2) is collected after the patient has voided about 200 mL. The patient is then instructed to stop voiding, at which time the physician massages the prostate and collects the prostatic fluid expressed prostatic secretions (EPS). Afterward, the patient voids again, and a 10-mL specimen (VB3) is collected. Cultures are sent on the 4 specimens hence the 3-glass or 4-glass test (nomenclature). When the bladder urine is sterile, vesical, and prostatic infection can be differentiated by comparing the bacterial colony counts of VB1 and prostatic fluid, EPS and VB3 counts. In urinary infections, the VB1 count is much higher than the EPS or VB3 count. The EPS and VB3 counts in prostatic infections significantly exceed the VB1 count. When interpreting bacterial colony counts, the clinician must take into account that the VB3 specimen is a 100-4 dilution of prostatic fluid. When the bladder urine is infected, the infection is localized by localization because all specimens will show heavy growth of organisms. Note that this test is often replaced by the 2-glass test, which collects a more convenient pre-postprostatic massage urine sample. The premassage and postmassage 2-glass test has strong concordance with the 4-glass test and is a reasonable alternative when EPS are not obtained. The technique and diagnostic algorithm are discussed in Section I: “Prostatitis, General” and “Prostatitis, Chronic, Bacterial (NIH VI).”

**REFERENCES**

**STEINER STRASSE**

**DESCRIPTION**

A German expression for “street of stones,” referring to multiple stone fragments in the ureter after extracorporeal shock wave lithotripsy. Characteristically, stone fragments are found in a line within the ureter, which may or may not be obstructed. The condition occasionally presents with renal colic, nausea, or vomiting. Observation is sufficient if symptoms are tolerable or absent; with severe colic or obstruction, treatment is ureteral stent placement, percutaneous nephrostomy, or ureteroscopy lithotripsy (Image 4).

**REFERENCE**

**STING PROCEDURE**

This refers to subureteral transmural injection (“STING”) of bulking agents to correct vesicoureteral reflux. The original coined term was subureteric Teflon injection (STING) using percutaneous Teflon (PTF) particles suspended in glycerol. Due to concern over migration of the Teflon to the brain and lung it was abandoned in favor of other agents. Silicone was also used as a bulking agent (Macroporl) and white effective was also abandoned due to safety concerns. Other materials such as polydilatex (cross-linked bovine collagen Contigen) and vasculocryopiapate (Cryopef) are also no longer used a bulking agents. Bulking agents such as Deflux (cross-linked dextranomer hyaluronic acid copolymer) has been accepted and is currently in widespread use. The basic technique involves the perireteral injection at the 6 o’clock position of the ureteral orifice. A modification is the hydrodistention implantation technique (HIT) where the agent is injected into the ureteral lumen filling the ureter. Overall the success rate is inferior to that of open surgery. About 70-90% have reflux resolution after 1 procedure. With repeat STING procedures, the success rate increases to 90-95%. See also Section I: “Vesicoureteral Reflux, Pediatric”; and Section II: “Bulking Agents, Intractable.”

**REFERENCES**

**STRAIGHTURIA**

**DESCRIPTION**

Slow, painful, spasmic expulsion of urine in a drip-wise fashion, usually occurring at the end of micturition due to spasm of the bladder and urethra. Associated with an irritative process in the GU system, it often refers pain to the perineum. Historically, the pathophysiology has been attributed to a significant inflammatory component. The term is not commonly used in human medicine, but is firmly entrenched in veterinary medicine.

**SYNONYMS**

• Strangury

**REFERENCES**

**STREAK GONAD**

**DESCRIPTION**

Streak gonads are hypoplastic and dysdifferentiating gonads mainly consisting of fibrous tissue. Patients with streak gonad usually present with female phenotype, primary amenorrhea, infantile breast development, sparse pubic and axillary hair, infantile external genitalia and vagina, atrophic vulvar labia, immature ovaries, high serum FSH, low urinary estrogen, and osteoporosis, as well as the streak gonad. Diagnosis is made by measuring FSH and urinary estrogen, and determining karyotype. See Section I: “General Gynecology, Mixed and Pure.”

**TREATMENT**

• Management includes laparoscopy with excision of any intra-abdominal tests or streak gonads. These masses progress to malignancies, which may develop before puberty.

• Femoral vein and reconstructive surgery are advised in cases with severely deficient visualization of the genitals.

**REFERENCES**

**STICKLER URETERAL ANASTOMOSIS**

**DESCRIPTION**

“Through an extravesical approach, a 3.5-cm tunnel encircling the ureter is made in the vagina, and a Small clamp is used to create a submucosal 3–4 cm tunnel extending out of the colon laterally. The ureter is dissected through the tunnel, the spasticity is anastomosed to the vagina, and the tapering of the ureter is closed using a transvaginal platinum wire.”

**REFERENCES**

**STROCULINERAN AMMONIUM PHOSPHATE HEXAHYDRATE**

**DESCRIPTION**

The mineral name for magnesium ammonium phosphate hexahydrate (MgNH4PO4·6H2O) stone. Struvite stones (also sometimes known as triple phosphate stones) are composed of calcium magnesium ammonium phosphate and form only in urine infected by anaerobic bacteria, such as Proteus, Providencia, and sometimes Klebsiella, Pseudomonas, and enterococcus. Because of their potential for rapid growth and substantial morbidity, early detection and eradication are essential (See also Section I: “Urolithiasis, Sheep”).

SUPERNUMERARY KIDNEY
DESCRIPTION
A supernumerary kidney is a rare condition in which a free accessory renal organ exists as a distinct entity, with its own blood supply, with presence of 2 normal kidneys. It is distinguished by its small size and abnormal abnormally-shaped kidney. It is either a component of a bilateral ureteral system or a completely duplicated system. When diagnosed, treatment for a supernumerary kidney should be based on pathologic processes affecting the kidney rather than its redundant appearance or abnormal position. Association of a normal kidney with a 2nd or 3rd (isolated) smaller kidney is an extremely rare anomaly with only a total of 81 cases reported through 2013.

REFERENCE

SUPINE STRESS TEST
DESCRIPTION
Nonurodynamic method to test for intrinsic sphincteric deficiency, it is performed by placing the patient in lithotomy position and tilting the empty bladder with 200 cc saline under gravity. The patient is then asked to cough and perform aValsalva maneuver. A test is deemed positive if fluid is seen leaking from the meatus at time of cough or Valsalva. Studies have shown that it is a relatively quick and inexpensive test that has a sensitivity of 93.5% and specificity of 90.0%.

SYMPTOMATIC UROLOGY CONSIDERATIONS
DESCRIPTION
The kidney (lupus nephritis) is the organ most commonly affected by systemic lupus erythematosus (SLE), a chronic, multisystem autoimmune disease with no known cause. A variety of diseases related to SLE can affect the kidney, with renal biopsies usually necessary to identify the specific type. The renal manifestations of SLE vary from patient to patient. Proteinuria with or without an elevated creatinine is the most common manifestation of renal disease in SLE. Protein excretion typically shows a red and white blood cells per high power field and/or ≥1 cellular cast in more severe forms of disease. Immune complexes result in injury to the glomerulus, and the specific lesion is determined by renal biopsy. International Society of Nephrology classification divides the SLE glomerular disorders into different classes: Classes I and II (minimal mesangial lupus nephritis and mesangial proliferative lupus nephritis) are the mildest forms; classes III and IV (focal proliferative lupus nephritis and diffuse proliferative lupus nephritis) more severe forms; and Classes V and VI (membranous lupus nephritis and advanced sclerosing lupus nephritis) are the most severe forms. These more severe forms of lupus nephritis can cause impaired renal function, proteinuria, and the nephrotic syndrome. In addition to these glomerulopathies, SLE can also result in interstitial nephritis and renal vascular disease. Renal manifestations are dependent on the underlying cause such as infection, antifibrin therapy [infliximab and etanercept], chlorpromazine, diltiazem, hydralazine, interferon-β, isoniazid (INH), minocycline, penicillamine, quinidine, methyldopa, procainamide) can cause drug-induced lupus nephritis. Rarely, certain medications (eg, antifibrin therapy [infliximab and etanercept], chlorpromazine, diltiazem, hydralazine, interferon-β, isoniazid [INH], minocycline, penicillamine, quinidine, methyldopa, procainamide) can cause drug-induced SLE. Mild forms are not treated, but more severe forms are treated with corticosteroids (cyclophosphamide therapy) and prednisone. Renal replacement may be needed in the most severe forms.

TANNER STAGES/CLASSIFICATION OF SEXUAL MATURITY

DESCRIPTION

The Tanner scale defines physical measurements of the onset and development of pubertal changes based on external primary and secondary sex characteristics, such as breast and genitalia development and the growth of pubic hair. It is useful in the evaluation of delayed or precocious puberty.

- Pubic hair (boys and girls) – Stage 1: Prepubertal (none or vellus hair similar to abdomen wall)
- Stage 2: Span of growth of long, slightly pigmented hair, straight or curled, at base of penis or along labia
- Stage 3: Darker, coarser, and more curled hair, spreading sparsely over junction of pubes (male) or spreading to medial surface of thighs (female)
- Stage 4: Adult in type and quantity, with horizontal distribution (feminine type)
- External genitalia (boys) – Stage 1: Prepubertal
- Stage 2: Enlargement of scrotum and testes; scrotal skin reddens and changes in texture
- Stage 3: Enlargement of penis (length at 10°)
- Stage 4: Increased size of penis, with growth in breadth and development of glans; testes and scrotum large, skin darker
- Stage 5: Adult genitalia

- Breast development (girls) – Stage 1: Prepubertal
- Stage 2: Breast bud stage with elevation of breast and papilla; enlargement of areola
- Stage 3: Further enlargement of breast and areola; no separation of their contour
- Stage 4: Areola and papilla form a secondary mound above level of breast
- Stage 5: Mature stage. Projection of papilla only, related to recession of areola

TERATOMA, SACROCOCCEAL, UROLOGIC CONSIDERATIONS

DESCRIPTION

Sacroccgeal teratomas are usually diagnosed in the neonate (1 in 40,000 births) and less often in infants or adults. Females are more affected than males. A clinical presentation is usually in the form of palpable mass, skin discoloration, or halyne hery. Related diseases include bilateral aortoarteritis, neurologic MRI, bladder or bowel dysfunction (obstruction or incontinence), high-output cardiac failure, or fetal hydrops. Sacroccgeal teratomas of the newborn are generally benign, whereas those discovered later have a 50% chance of being malignant. Wide, local excision of the tumor is primary management.

REFERENCE

TESTICULAR BIOPSY, INDICATIONS

DESCRIPTION

Testicular biopsy was once considered a cornerstone in the diagnosis of unexplained male infertility and azoospermia, but its current indications are now limited to a specific subgroup of patients. Current practice guidelines limit biopsy to those with obstructive azoospermia, those who require TESE (testicular sperm extraction), and to confirm the diagnosis of carcinoma in situ (CIS) of the testis. In men with obstructive azoospermia confirmation of the presence of normal spermigenesis is usually helpful before surgical correction of the obstruction. TESE often requires multiple testicular biopsies for sperm harvesting with part of the specimen to be used for histologic exam. In special situations where ultrasonographic abnormalities indicate the potential presence of CIS, namely testicular microcyst, intracyomugly, or a solid testicular mass, a testicular biopsy may prove to be helpful before orchiectomy.

REFERENCE

TESTIS, CARCINOID

DESCRIPTION

Carcinoid tumors of the testes are rare neoplasms that originate from neuroendocrine cells. Most carcinoid tumors are found in the Gi tract, particularly in the ileum or appendix. Because of their neuroendocrine precursors, some tumors elicit endocrine activity. 88% secrete 5-hydroxytryptamine (5-HT), a metabolite of serotonin. Carcinoind syndrome results from the vasoactive substances secreted from the tumor and can cause symptoms such as flushing, sweating, wheezing, diarrhea, abdominal pain, and fibrosis of cardiac valves. Carcinoind tumors of the testes can be divided into 3 groups: Primary metastasis to a primary site, or carcinoind tumor originating from a testicular teratoma. Most patients present with a painless scrotal mass, unlike germ cell tumors (GCT), there is no predilection unlike germ cell tumor (GCT), there is no predilection.

Because of their neuroendocrine precursors, some tumors elicit endocrine activity. 88% secrete 5-hydroxytryptamine (5-HT), a metabolite of serotonin. Carcinoind syndrome results from the vasoactive substances secreted from the tumor and can cause symptoms such as flushing, sweating, wheezing, diarrhea, abdominal pain, and fibrosis of cardiac valves. Carcinoind tumors of the testes can be divided into 3 groups: Primary metastasis to a primary site, or carcinoind tumor originating from a testicular teratoma. Most patients present with a painless scrotal mass, unlike germ cell tumors (GCT), there is no predication for a particular age group (~16% of patients have carcinoid tumors). Tumors localized to the testes have an excellent prognosis; however long-term follow-up is needed, due to risk of late metastasizes.
As with all testicular neoplasms, treatment begins with radical orchiectomy, with high lynage of the spermatic cord. Chemotherapy or radiation therapy has been reported, but these treatment modalities have poor efficacy. Oncocytic analays have been reported to stabilize disease progression, as well as help relieve symptoms of carcinoma. Once discovered, other extratesticular sources of carcinoma should be determined. S-HAA can be measured in the urine and can be a useful adjunct. GI endoscopy, CT scan, MRI scanctigraphy, or sonomography in renatorc scintigraphy can be used to search for GI causes of carcinoma tumor.

REFERENCE

TESTIS, CARCINOMA IN SITU (CIS) / INTRATUBULAR GERM CELL NEOPLASIA (ITGCN)

DESCRIPTION

Testicular CIS is considered to be the precursor to all GCT, except for yolk sac tumors and spermatocytic seminoma. CIS may be present during infancy; however, lesions do not proliferate until adolescence, when hormonal influences come into play. Studies have shown that 50% of males with CIS developed invasive tumor growth within 5 yr. Virtually all patients with CIS will progress to testicular carcinoma. Risk factors for testicular CIS are cryptorchidism, contralateral testes cancer; extratesticular GCT, infertility, and intense patients with a Y chromosome. There is controversy concerning the screening, management, and treatment of testicular CIS. Diagnosis is made through tests biopsy. Treatment options involve surveillance, radiation, and orchiectomy. Capable baseline imaging or CIS has been associated with incomplete treatment and recurrence. High-risk patients may be offered testicular biopsy and orchiectomy, although some physicians would advocate surveillance alone. Surveillance is a viable treatment option due to the long, protracted nature of CIS, the morbidity of treatment options, and the fact that effective treatment of GCT exists. Radiation (14–20 Gy) may be performed in the patient with unilateral CIS and contralateral CIS, or in the patient with bilateral CIS. Orchiectomy is offered to the patient with unilateral CIS and a normal contralateral testis. Extensive counseling regarding the risks and benefits of surveillance vs. biopsy and subsequent treatment is needed. The option to orchiectomy sperm should be offered as well. (See also Section II “Testis, Microtubules.”) [Image 41.]

REFERENCE

TESTIS, CYSTIC LYPHANGIOMAS

DESCRIPTION

Testicular cystic lymphangiomas, benign tumors of unknown etiology, are often misdiagnosed as other conditions like hematoceles, hematoceles, watch, or possible torsion in children. Lymphangiomas are characterized by an extensive overgrowth of lymphatic vessels; 50% are present at birth, 90% are evident by the age of 2 yr. Gradual painless scrotal swelling is the common symptom. On palpation, the mass may be soft and spongy or firm and tense, usually not separable from the scrotal skin. Skin showing bluish/grayish discoloration or erythematous changes is often present. The ultrasound exam usually shows a complex multiloculated septated cystic mass without calcifications. Often, these lesions are more suggestive of hydrocele, hematocele, varicocele, or possible torsion. Ultrasound examination can be used to search for GI causes of carcinoma tumor.

REFERENCE

TESTIS, TUMORS

DESCRIPTION

Testicular hemangioma is a very rare neoplasm, usually 25 cases are in the English literature. Intratesticular tumors of vascular origin are extremely rare. Intratesticular hemangioma can mimic malignant testicular tumors on presentation and imaging. Testicular hemangioma histologically comprises 3 types: Cavernous, capillary, and epithelial. Patients usually present with testicular enlargement with or without tenderness. Although it is impossible to differentiate a hemangioma from a seminoma preoperatively, intraoperative frozen study may be helpful in the differential diagnosis. Frozen section must be performed, if the neoplasm has significant vascular proliferation identified by Doppler sonography. In these cases, testicular conservative surgical treatment by means of tumor enucleation and even radical orchiectomy over concern for malignancy. A more conservative approach with serial ultrasonographic scanning has been advocated if a clear distinction can be made between neoplastic and nonneoplastic testicular cysts. Selecting cases can potentially be managed by intraoperative frozen section to demonstrate no malignancy and enucleation of the tumor performed.

In children, testicular tumors are rare and the majority are benign, especially before puberty. Radiation therapy can be used to treat testicular tumors, although radiation after puberty may be less effective. Pediatric simple testicular cysts are very rare, as most cysts occur in men 60 yr. Most can be treated with testicular-sparing surgery. The diagnostic differential of testis cysts in the pediatric population:

Hydatid cysts are rarely seen, except in the Middle East. These are very rare lesions and are generally clinically interpreted as neoplastic, until proven otherwise at the time of postoperative pathology. Treatment has included excision and even radical orchectomy for concern over concern for malignancy. A more conservative approach with serial ultrasonographic scanning has been advocated if a clear distinction can be made between neoplastic and nonneoplastic testicular cysts. TESTIS, LYMPHOMA

DESCRIPTION
Most common testicular malignancy in men >60, and the most common secondary neoplasms of the testis. Initial presentation is usually painless testicular swelling. Diagnosis is made through orchectomy. Bilateral involvement occurs in ~50% of cases; 10% are synchronous. Treatment is multidisciplinary; orchectomy is performed, followed by systemic chemotherapy (dacarbazine, CHOP prophylaxis), and local radiation. (See also Section II: “Lymphoma, Urologic Considerations” and Image Q5.)

REFERENCES

TESTIS, METASTASIS TO

DESCRIPTION
Due to the nature of the disease, this metastasis usually presents in men >50. Spread to the testis may be hematogenous, lymphatic, or by direct extension. Most primary malignancies are prostate, lung, GI tract, melanoma, and kidney cancer (Image Q5).

REFERENCE

TESTIS, MICROLITHIASIS

DESCRIPTION
Numerous and diffuse calcifications throughout the entire testicle seen on transscrotal ultrasound. Adenocarcinoma in ultrasound technology have led to an increased detection of testicular microlithiasis. It is reported in undescended testes (0.3% incidence), prepubertal Klinefelter syndrome, and male pseudopseudophedrophimoids, and is slightly more common in postpubertal males. Infertility and malignancy have been reported to be associated with the condition, and some consider it possibly premalignant. Both seminomas and nongerm-cell-GCT have been described in association with microlithiasis. Others suggest an association with carcinoma in situ of the testis, but this is not settled. Recent studies have a prevalence of 2% in boys who undergo scrotal US, most commonly bilateral, with increased risk of malignancy. Most advocate close surveillance of patients with testicular microlithiasis, such as yearly testicular ultrasound, physical exam, and judicious tumor marker determinations (Image Qb).

REFERENCES

TESTIS, NORMAL SIZE

DESCRIPTION
Testis size measurements can be made by ultrasound (0.9) (most accurate) or Ponder orchitectometry. At birth, testicular length is ~1.5 cm with a volume of 1.1 cm³. In prepubertal boys, testicular length is usually ~2 cm and volume ~2 cm³.

Normal testicular size after puberty in an adult is about 4.5–6.5 cm with a volume ranging from 15–30 cm³.

REFERENCES

TESTIS, RETRACTILE

DESCRIPTION
A testicle that can ride high in the scrotum or near the external inguinal ring; caused by a lack of cremasteric reflex. The testicle is able to be gently manipulated into the scrotum. Usually considered a variant of normally descended testes; 3% of retractile testes may ultimately become undescended (descending or acquired undescended), and this is seen more frequently in boys <7 yo. Boys with retractile testes should be followed annually until the outcome of descent or nondescence is clear, which in many cases won’t be until puberty.

REFERENCE

TESTIS, SEX CORD STROMAL TUMORS

DESCRIPTION
These tumors arise from the supporting structures of the testes and not the germ cells. They usually present as a mass, are rarely hormonally active, and do not produce tumor markers such as hCG, usually other than the presence of tumors ranging from 15–30 cm³.

REFERENCES

TESTIS, VASOCONGESTION

DESCRIPTION
“Blue balls” is a colloquialism for acute testicular/scrotal pain in such patients. Secondary neoplasms of the testis. Initial presentation may be more common among young male adults and is usually painless testicular swelling. Diagnosis is made through testicular ultrasound, physical exam, and judicious tumor marker determinations (Image Q5).

REFERENCES

TESTIS, TERATOMA, EXTRAGONADAL

DESCRIPTION
Primary tumors of extragonadal origin are rare. In a decreasing order of frequency, the most common sites are the mediastinum, retroperitoneum, sacrococcygeal region, and pineal gland. Theses include a proliferation of primitive germ cells that takes place during early embryonic migration from the yolk sac endoderm, and pluripotent cells that persist in sequestered primitive rests during early somatic development. Histologically, all types of GCT are represented, with pure seminoma accounting for 1/2 of medullary and retroperitoneal tumors. Clinically, males are affected more than females, with the exception of sacrococcygeal tumors, where females predominates. The majority of adults present with advanced local disease and distant metastasis. Patients with mediastinal extragonadal tumors are usually diagnosed in their 20s, with or without symptoms of chest pain, cough, or dyspnea. Patients with primary retroperitoneal tumors may present with abdominal or back pain, a palpable mass, or venous obstruction. Tumors of the pineal gland usually present in children and young adults, with symptoms of increased intracranial pressure, ocular movement defects, hearing loss, hypothalamic dysfunction, or hypothalamic-pituitary disturbances. Five needle aspiration (FNA) can be used to assist in the diagnosis, but carries the risk of insufficient cellular return. When suspicion for teratoma exists, it is important to differentiate between mature and immature teratoma as immature carries the risk of malignant transformation.

TREATMENT

• Intensive chemotherapy regimens have shown some success in primary retroperitoneal seminoma.
  • The nonseminomatous version has done poorly despite surgery, radiotherapy, and chemotherapy.
  • Primary radiation therapy has been much favored for pineal tumors if CSF spread is required.

792
Both prostate cancer and hypogonadism become more prevalent as men age; testosterone levels can be found in complete hypogonadism, sexual dysfunction, osteoporosis, and hepatic cirrhosis.

- Generally accepted normal ranges total testosterone (may vary by lab):
  - Prepubertal children: 2–5 ng/dL.
  - Men (≥17 yr): 300–1,000 ng/dL (10.4–34.7 nmol/L).
  - Women: 20–70 ng/dL (0.7–2.6 nmol/L).
- A total testosterone level (free plus protein-bound) < 200 ng/dL (or 6.9 nmol/L) (American Association of Clinical Endocrinologists) or < 100 ng/dL (or 3.4 nmol/L) (FSH) is associated with hypogonadism and warrants further workup in an adult.
- Free testosterone (adult male range 8.8–27 pg/mL) is a useful diagnostic test as well, as elevated or decreased sex hormone-binding globulin (SHBG) changes the bioavailability of testosterone. It can be used as an adjunct to the patient with low total testosterone levels. For example, obesity is characterized by reduced total testosterone and normal free testosterone due to reduced protein binding.
- Serum SHBG concentrations increase with age. With increasing age, less of the total testosterone is free or biologically active, as SHBG binds testosterone with high affinity.
- Serum T peaks early morning and then declines over the course of the day until the nadir in the evening (10–15% lower than morning values, but may vary up to 50% in younger men).
- Testosterone replacement monitoring: For men on injections. Target T should generally be in the range of 400–700 ng/dL (13.9–27.7 nmol/L). If higher, the patient should be re-evaluated for monitoring.

Methods used to measure T: Radioimmunoassay (RIA), Enzyme-linked Immunoassay (EIA) and Liquid Chromatography-Mass Spectroscopy (LC-MS) with high affinity.

- With high affinity.
- Increasing age, less of the total testosterone is free or biologically active, as SHBG binds testosterone with high affinity.
- Serum T peaks early morning and then declines over the course of the day until the nadir in the evening (10–15% lower than morning values, but may vary up to 50% in younger men).

Testosterone replacement therapy following radical prostatectomy:

- Testosterone replacement therapy, prostate cancer risk

- DESCRIPTION

  Multiple published review articles have shown that testosterone replacement therapy (TRT) does not cause prostate cancer or placebo patients at increased risk for the development of prostate cancer.

  A recent audit of the UK Androgen Study showed that initiating testosterone treatment had no statistically significant effect on the incidence of prostate cancer. These findings from this study show that, with careful monitoring, men with symptoms of testosterone deficiency can be treated safely with TRT without an increased risk of developing or progressing already present prostate cancer. See also Section I: “Testosterone Replacement Therapy, General Principles.”

TREATMENT

Apply antifungal agents on overt lesions. Agents may be used for preoperative surgical planning or may be used intraoperatively as well.

REFERENCES

THORACIC KIDNEY

DESCRIPTION

A type of renal ectopia in which the kidney is found in the posterior mediastinum, partially or completely above the level of the diaphragm. The diaphragm is thin, yet envelops the protruding kidney, keeping it separate from the pleural cavity. Although in some cases they may in fact be in a position more cranially, the vast majority of patients are asymptomatic. (See also Section II: “Renal Ectopia.”)

REFERENCE

TINEA CRURIS (JOCK ITCH)

DESCRIPTION

Dermatophytic infection of the crural areas of the genitalia. Caused by dermatophytes Trichophyton soudanense, Trichophyton megacephalum, and Epidermophyton floccosum. Clinically, reddish brown lesions are seen in the crural areas of the genitalia. Penis involvement is rare. Postinflammatory hyperpigmentation may occur as a result of chronic or recurrent disease. Culture or KOH exam is necessary to confirm diagnosis. Scrupulous should be performed on the active border of the lesion and reveals branching septate hyphae. Differential diagnosis includes erythrasma, psoriasis, and seborrheic dermatitis. Renal function is not unusual, and treatment should be aimed toward active disease rather than postinflammatory hyperpigmentation. (See also Section II: “Erythrasma.”)

TREATMENT

- Prevent skin maceration by keeping skin dry.
- Apply antifungal agents or ointments. Agents include clotrimazole, miconazole, clotrimazole, and miconazole (3% or 4% cream) for 14 days (requires baseline lab monitoring CBC, LFTs).

REFERENCE

TMPRSS2-ERG GENE FUSION, PROSTATE CANCER

DESCRIPTION

Fusion of the transmembrane protease, serine 2 (TMPRSS2) and erythroblastosis virus E26 (ERG) genes is known as the TMPRSS2-ERG gene fusion. It is present in up to 80% of human prostate cancers. This gene fusion contributes to development of androgen independence in prostate cancer through disruption of androgen receptor signaling. TMPRSS2-ERG, in combination with androgen prostate cancer antigen 3 (PCA3), improved the performance of Prostate Cancer Prevention Trial risk calculator in predicting cancer on biopsy. The men were stratified into 3 groups based upon the levels of TMPRSS2:ERG and PCA3 in their urine: low, intermediate and high. Prostate cancer was diagnosed in the groups, respectively: 21%, 43%, and 69%. Grade prostate cancer (>4000 score), was diagnosed 3% in each group, respectively. TMPRSS2:ERG and PCA3 urine analysis appears to enhance the utility of serum PSA for predicting prostate cancer risk and clinically relevant cancer on biopsy. (See also Section II: “PCA3 (Prostate Cancer Gene 3) Urine Assay.”)

REFERENCE

TOILETING PROGRAMS

DESCRIPTION

Type of behavioral training to treat urinary incontinence. The patient is instructed to establish a routine voiding schedule regardless of the sensation to void. Initially, the patient is told to void at frequent intervals (e.g., every 1–2 hr), the time between voids is then increased, usually until the child establishes an acceptable period (usually 2–4 hr) of continence.

REFERENCE

TRANSESOPHAGEAL ECHOCARDIOGRAPHY (TEE), UROLOGIC CONSIDERATIONS

DESCRIPTION

A useful diagnostic tool in the management of renal tumors with tumor thrombus; the TEE is used to identify the extent of tumor thrombus involvement in the inferior vena cava. This may be used for preoperative surgical planning or may be used intraoperatively as well.

**TRICHOMONIASIS**

**DESCRIPTION**
Sexually transmitted infection caused by the protozoon *Trichomonas vaginalis*. It is a rare cause of nongonococcal urethritis in men. Common cause of vaginitis in women (from 4–10%). It is associated with a high prevalence of concomitant bacterial infection in women. STIs and associated infections include urinary discharge, dysuria, and the presence of neoplasms in uterine secretions. Some women have symptoms characterized by a diffuse, matted, yellow-green vaginal discharge with vaginal irritation. However, many women have minimal or no symptoms. Because of the high prevalence of *Trichomonas* in clinical and non-clinical settings, testing for the organism should be performed in women seeking care for vaginal discharge. Trichomoniasis has any, only minor influence on male fertility. In women, it can cause premature rupture of the membranes and premature delivery, as well as fetal infertility and cerebral palsy. Females may have an elevated vaginal pH of >4.5. A positive diagnosis is made by identification of the protozoon on wet mount (must be examined in 15–20 min). Culture on Diamond’s medium may take up to 7 days; a more rapid commercial culture method is available. (See also Section I: “Sexually Transmitted Infections.”)

**CONSIDERATIONS**
Antimicrobials (eg, metronidazole gel) are unlikely to achieve therapeutic levels in the urethra or perivaginal glands; therefore, use of this gel is not recommended. This is a common cause of coinfection and is associated with a high prevalence of coinfection of the high prevalence of *Trichomonas* in clinical and non-clinical settings, testing for the organism should be performed in women seeking care for vaginal discharge. Trichomoniasis has any, only minor influence on male fertility. In women, it can cause premature rupture of the membranes and premature delivery, as well as fetal infertility and cerebral palsy. **TRICHTHOTILOMANIA, PUBIC**

**DESCRIPTION**
Trichotillomania is the obsessive-compulsive habit of pulling or shaving hair from the pubic area. It is considered a willful self-harm practice. Behavioral counseling is indicated. (See also Section II: “Vaginal Discharge, Urologic Disease.”)

**REFERENCE**

**TRICHOMONAS VAGINALIS**

**DESCRIPTION**
*Trichomonas vaginalis* is a common cause of vaginitis in women. This is the most common sexually transmitted infection in the United States and is associated with a high prevalence of concomitant bacterial infection. The organism is identified and cultured on Diamond’s medium. Culture on Diamond’s medium may take up to 7 days; a more rapid commercial culture method is available. (See also Section I: “Sexually Transmitted Infections.”)

**CONSIDERATIONS**
Metronidazole gel is considerably less efficacious for treatment of trichomoniasis (<90%). Both tests are considered point-of-care diagnostic tests for trichomoniasis in women include OSOM Trichomonas Rapid Test (Genzyme Diagnostics, Cambridge, Massachusetts), an immunochromatographic rapid dipstick technology, and the AfiTray VF II (African Dickinson, San Jose, California), a rapid acid probe test that evaluates for T. vaginalis, G. vaginalis, and C. albicans. Each of these tests, which are performed on vaginal secretions, has a sensitivity of >83% and a specificity of >97%. Both tests are considered point-of-care diagnostic tests. Treatment is metronidazole 2 g PO or Tinidazole 2 g orally in a single dose for 72 h. Considered a normal finding and distinct from *Trichomonas* in women of reproductive age and in up to 75% after menopause. Considered a normal finding and distinct from *Trichomonas*, which is considered a premenopausal lesion. Cystoscopically, these are pale white-gray areas with irregular borders. This condition is not seen in men, except for some reports in men receiving estrogen for prostate cancer. Treatment is not necessary. (See also Section II: “Vaginitis, Genitourinary.”)

Trichotillomania is the obsessive-compulsive habit of cutting or shaving the hair. It is considered a willful self-harm practice. Behavioral counseling is indicated. (See also Section II: “Vaginal Discharge, Urologic Disease.”)

**REFERENCE**

**TRICHTHOTILOMANIA, PUBIC**

**DESCRIPTION**
Trichotillomania is defined by the Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM-IV) as hair pulling by a patient’s repetitive self-pulling of hair leading to a noticeable loss of hair. Any body area, including the pubic region, can be involved. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning. Most individuals start pulling their hair during childhood or adolescence and may also consume the hair. Anxiety, depression and obsessive-compulsive disorders are frequently encountered in patients with trichotillomania. Treatment is a combination of education, behavior therapy and, if necessary medication such as antipsychotics. (See also Section II: “Trichotillomania, Pubic.”)

TRISOMY 20 P

DESCRIPTION
A trisomy producing microcephaly, low-set ears, deaf palate, peeled nose, and microphthalmia. Renal anomalies (e.g., renal agenesis, hypoplasia, dysplasia, and polycystic kidney) are common. Other anomalies include heart malformations, congenital diaphragmatic hernia, and limb abnormalities. Trisomy 20 P is also associated with increased risk of leukemia, Wilms tumor, and neuroblastoma.

REFERENCE

TRISOMY SYNDROME
A congenital condition characterized by the presence of 3 instead of 2 copies of any one of the autosomal chromosomes. These disorders often result in a wide range of phenotypical expressions, including GI anomalies. Examples include trisomy 18 and 13, which produce syndromes similar to Down syndrome and trisomy 21, respectively, and trisomy 21, which is associated with sporadic papillary RCC.

REFERENCE

TRUE HERMAPHRODITISM (OVO-TESTICULAR DISORDER OF SEXUAL DIFFERENTIATION (O-TESTO-SD))

DESCRIPTION
True hermaphroditism or ovo-testicular disorder of sexual differentiation (O-TESTO-SD) is 1 of the rarest varieties of all disorders of sexual differentiation. Among 5000 cases, only 100 have been reported. The gonads and histology of each patient are classified as:
- Prepubertal: Testis on 1 side and ovary on the other side
- Lateral: Testis and contralateral ovary (30%)
- Bilateral: Testicular and ovarian tissue identified on either side, usually as ovotestis (50%)
- Unilateral: Ovotestis on 1 side and testis or ovary on the other side, typically as ovotestis

REFERENCE

TUBERCULOSIS, BLADDER AND URETHRA

DESCRIPTION
The hematogenous dissemination of TB can affect the entire urinary system. Bladder TB is caused by a descending infection from renal TB. Urethral TB is rare and can present as perineal tubulitis and abscesses. Symptoms include urinary frequency, urgency, and dysuria, with mucosal ulcerations and friability, and diminished bladder capacity. (See also Section II: “Tuberculosis, Genitourinary.”)

DIAGNOSIS
- Urine culture of acid-fast bacilli: Typically 1st morning void, requires multiple sequential cultures.
- Urethral TB is typically diagnosed on biopsy.
- Imaging such as IVU and CT may be normal, but can aid in diagnosis.

TREATMENT
- Combination antituberculous treatment: Typical regimen: 6 mo of rifampicin, isoniazid, pyrazinamide, and ethambutol
- Urethral TB may require suprapubic cystostomy tube drainage and urethral dilation for stricture.

REFERENCE

TUBERCULOSIS, MALE EXTERNAL GENITALIA

DESCRIPTION
Rare manifestation of TB that may present as a papulonecrotic ulcer, tubercular granulomas, or a cold nodule, which may be clinically indistinguishable from malignant disease. Diagnosis is confirmed on biopsy, treatment is systemic antituberculous medication. (See also Section II: “Tuberculosis, Genitourinary.”)

REFERENCE

TUMOR LYsis SYNDROME (TLS)

DESCRIPTION
A syndrome associated with chemotherapy, radiation, and other treatments in which massive tumor lysis occurs, with subsequent release of large amounts of potassium, phosphate, and nucleic acids that are converted to massive amounts of uric acid. More commonly associated with chemotherapy of lymphomas and leukemias, it can be seen with any tumor type. Extensive metastatic tumor, pretreatment renal impairment, and markedly elevated LDH concentrations have been reported to be serious risk factors in developing TLS. Sub investigations would reveal hyperuricemia, hyperphosphatemia, and concurrent metabolic
acids, as well as severe hyperuricemia with eventual renal failure. If these patients are being treated with allopurinol, they are at risk of ARF and xanthine stone formation (See also Section II: “Nephropathy, Urate Acidosis, and Gouty Arthritis”).

TREATMENT
- Prevention with adequate hydration (urine output of >40–60 mL/h).
- Cautious use of xanthine; some recommend allopurinol.
- Urinary alkalization should not be done, as it may cause further precipitation of calcium phosphate in the kidney and other tissues.

REFERENCE

TUNICA VAGINALIS TUMORS
DESCRIPTION
Malignant mesothelioma of the tunica vaginalis is rare (0.3–1.5% of all malignant mesotheliomas) and often fatal. However, increased frequency has been reported since 1980. Most of the patients are 40–79 yr of age, with prior exposure to asbestos being reported in some. Microscopically, mesothelioma may be epithelial, biphasic, or a combination of both. The malignant nature of the disease is indicated by its frequent mitosis, nuclear atypia with prominent nuclei, and invasion of adjacent structures or lymphatics. Positive staining with keratin and failure to stain with CEA indicate mesothelioma. In addition, an immunoperoxidase stain has been reported to be specific for the tumor. CT and aspiration cytology may aid in preoperative diagnosis. The most important differential diagnostic considerations include mesothelial hyperplasia, adenomatoid tumor, carcinoma of the testis, and serous papillary tumors. The prognosis for this entity is poor, with a median survival of 23 mo and aggressive treatment with radical orchiectomy remains the mainstay of treatment. Adjunct chemotherapy may be tried. However, its value has not been established. (See also Section I: “Paratesticular Tumors” and “Scrotum and Testicle, Mass.”)

REFERENCE

TURNER SYNDROME (X0 SYNDROME)
DESCRIPTION
A sex chromosome abnormality with a 46, XO karyotype. It is the most common sex chromosome abnormality with an incidence of 1:10,000 newborn females. Neoplasms may have lymphomas. Clinically, patients present with short stature, primary amenorrhea, webbed neck, child-like chest, uneven pubic, and breast development. The external genitalia are female but immature, and most women with Turner syndrome are infertile. Karyotype analysis should be performed to confirm the diagnosis. Any patient with Turner syndrome who presents with virilization should also be evaluated for “Y chromosomal mosaic; as these individuals are at increased risk of gonadoblastoma or germ cell tumors.”

TREATMENT
- Endocrinopathy at diagnosis to detect cardiovascular anomalies (coronation of the aorta or a bicuspid aortic valve are most common causes of morbidity and mortality).
- Renal US to determine if GU abnormalities are present.
- Hormonal therapy in the form of growth hormone, estrogen, and medroxyprogesterone, aimed toward maximizing final height, reduction of secondary sexual characteristics, and menarche.

REFERENCE

TUNER-WARWICK INLAY URETHROPLASTY
DESCRIPTION
Through a midline scrotal incision, the urachal sinus is opened and scar tissue is removed, leaving a strip of urethra in place. The edges of the urachal incision are sutured to the urethral strip. In a 2nd stage, the mature manubialized urethra is tubularized with the surrounding scrotal skin and closed.

REFERENCE

UISS-UCLA INTERNATIONAL KIDNEY CANCER STAGING SYSTEM
DESCRIPTION
A prognostic system for renal cell carcinoma (RCC)–to-differentiate survival; the system integrates the 3 most commonly used prognostic factors: Cancer TNM stage, Furman grade, and patient performance status. Patients are categorized after nephrectomy into 3 risk groups: Low, intermediate, and high-risk for localized and metastatic disease.

REFERENCE

UNDERVIRILIZED MALE SYNDROME (MILD ANDROGEN INSENSITIVITY)
DESCRIPTION
A disorder of androgen receptor function caused by androgen receptor gene mutation. Patients with androgen receptor mutations have a 46, XY karyotype and present with a spectrum of phenotypes from complete external feminization, to ambiguous genitalia, to phenotypically intersex male, which is also known as undervirilized male syndrome. These patients present with gynecomastia at puberty, and may have scarce body hair, small penis, and complaints of impotence. Spanningnoma may or may not be impaired. Patients may have elevated lactosidase hormone, normal to slightly elevated testosterone, and high estradiol. Treatment may not be necessary, however, breast reduction surgery at puberty is sometimes necessary. Infertile men may benefit from assisted reproductive techniques (ART). (See also Section II: “Androgen Insensitivity Syndrome (AS or Androgen Resistance Syndrome). Complete and Partial Types.”)

REFERENCE

UNINHIBITED DETRUSOR CONTRACTION
DESCRIPTION
Uninhibited detrusor contraction leads to an overactive bladder. Bladder overactivity can result from damage to sensory inhibitory pathways, sensitization of peripheralafferent terminals in the bladder that unmask primitive voiding reflexes, or changes in bladder smooth muscle cells. Cystometry is essential if a definitive diagnosis is required. (See also Section II: “Overactive Bladder.”)

SYNONYMS
- Overactive bladder
- Unstable bladder

TREATMENT
- Traditionally, centers on the use of anticholinergic medications (oxybutynin, tolterodine, others).
- Estrogens may help in the postmenopausal woman.

REFERENCE

URACHAL ABNORMALITIES
DESCRIPTION
The urachus is a tubular connection between the allantoic stalk and the dome of the bladder. Fetal embryogenic resolution of this connection results in urachal abnormalities. Microscopically, urachal remnants are common, appearing in 3% of autopsy specimens, and are almost always asymptomatic. Except for the asymptomatic urachal diverticulum, the treatment of all urachal abnormalities is surgical, ie, complete excision of the abnormal structure, including a cuff of lateral. Congenital urachal abnormalities can be divided into 4 types:
- Urachal sinus: The most common urachal abnormality. The urachal sinus arises from a persistent patent urachus that drains to the umbilicus, may present with wetness, purulence, or malodorous discharge.
- Urachal cyst: Persistence of part of this channel between the bladder and umbilicus, lacking communication to either structure. The 2nd most common urachal anomaly. Most commonly presents in an older child with signs of suprapubic (Latin “calor, rubor, dolor”) in the lower abdominal wall. Occasionally, a urachal cyst will present as an asymptomatic median lower abdominal mass or tenderness.
- Urachal diverticulum of the bladder: May result from drainage of a urachal cyst to the bladder; presents with UTI.

REFERENCE
URACHAL CARCINOMA STAGING SYSTEMS

Urachal carcinoma is a malignant carcinoma that presents later in life. (See also Section I: “Urachal Carcinoma” and “Umbilical Abnormalities: Diagnostic Considerations” and Image 01.)

REFERENCE

URACHAL CARCINOMA STAGING SYSTEMS
DEFINITION
Two staging systems have been reported by Sheldon and Ashley. No formal TNM classification exists specifically for urachal carcinoma. (See also Section I: “Urachal Carcinoma.”)

REFERENCE

URATE, DIETARY
DESCRIPTION
Foods rich in urate should be restricted in patients with hyperuricosic calcium oxalate stone disease and in patients with acid stone disease. The intake of urate should not exceed 500 mg/day. urate-rich foods include:
- Carbohydrates, 200–500 mg urate/100 g
- Liver, 260–360 mg urate/100 g
- Kidneys, 210–255 mg urate/100 g
- Poultry skin, 300 mg urate/100 g
- Kidneys, 210–255 mg urate/100 g
- Liver, 260–360 mg urate/100 g
- Calf thymus, 900 mg urate/100 g
- Kidney, 210–255 mg urate/100 g
- Poppy seed, 300 mg urate/100 g
- Nettle, with skins: carottes, cornichons, sprats, 260–500 mg urate/100 g

REFERENCE

URAPLASMA UREALYTICUM
DESCRIPTION
Common bacterial inhabitant of the lower GI tract in adult men and women who are sexually active. As an STI it can also be transmitted vertically and from mother to offspring. It is the most common cause of nongonococcal and nonchlamydial urethritis, and can cause chorioamnionitis, pyelonephritis, and septic arthritis. It is implicated in chronic prostatitis in men, and urgency–frequency symptoms in women and in HIV-related acute epididymitis. It is also sometimes associated with decreased fertility. Diagnosis is by culture, but specific media and growth conditions are necessary. Treatment is doxycycline 100 mg/day for 2 wk or a single dose of azithromycin 1 g PO. (See also Section I: “Sexually Transmitted Diseases [STDs], General.”)

REFERENCE

URERET, AGENESIS/ATRESIA
DESCRIPTION
Isolated ureteral agenesis is incompatible with life. Unilateral ureteral agenesis indicates failure of ureteral bud development and is often accompanied by ipsilateral renal agenesis or multicystic kidney. Ureteral atresia is caused by varying degrees of failure in ureteral bud development. When either ureter or agenesis is unilateral, it is usually asymptomatic and of no clinical significance. However, it can be associated with infection (UTI) on occasion.

REFERENCE

URERET, DIVERTICULUM
DESCRIPTION
Ureteral diverticulum can be congenital or acquired, although most have been discovered in adults. Most diverticula are solitary outgrowths involving the distal ureter and upper portions of the pelvis. They are lined by urothelium, which is lined by transitional cell epithelium. Rupture of a diverticulum in the lower GU tract in adult men and women who are sexually active. As an STI it can also be transmitted vertically and from mother to offspring. It is the most common cause of nongonococcal and nonchlamydial urethritis, and can cause chorioamnionitis, pyelonephritis, and septic arthritis. It is implicated in chronic prostatitis in men, and urgency–frequency symptoms in women and in HIV-related acute epididymitis. It is also sometimes associated with decreased fertility. Diagnosis is by culture, but specific media and growth conditions are necessary. Treatment is doxycycline 100 mg/day for 2 wk or a single dose of azithromycin 1 g PO. (See also Section I: “Sexually Transmitted Diseases [STDs], General.”)

REFERENCE

URERET, DUPLICATED AND BIFID
DESCRIPTION
Duplication of ureters is a common anomaly. Duplication may be either complete or incomplete. Complete duplication is most often associated with vesicoureteral reflux, ectopic ureteral insertion, and ectopic ureteroceles, all of which are more commonly found in females than in males. Incomplete duplication is most often associated with UPJ obstruction of the lower pole of the kidney. Common clinical presentations include UTIs and urinary incontinence. Diagnosis is made usually in childhood by US, voiding urosonography, and Voiding cystourethrography. Also known as “double ureter” (partial duplication) or double ureters (if complete duplication). Treatment is urothelioysis in the presence of persistent

REFERENCE
fibroepithelial polyp. The bulk of the polyp is transitional epithelium. The incidence in ureter is 3–5% of all primary ureteral tumors. These benign tumors, hemangiomas usually cause incomplete obstruction and may eventually cause complete obstruction with dilation of the urinary tract. They predispose to UTI and may cause hematuria or abdominal flank pain. Up to 90% are associated with a duplicated collecting system in females and ~20% are nonduplicated ureters usually in males with an absent hemi-ureter. In females, the ureter typically inserts in the uterine or vaginal (dilated to the ophcyston) and cause incontinence or constant dribbling. In males the sites include the posterior urethra or seminal vesicles (no incontinence is seen) and often present later in life. Treatment is usually partial nephroureterectomy of the nonfunctioning upper pole moiety with nephrectomy often necessary for single ureter systems.

REFERENCE

URETER, FIBROEPITHELIAL POLYPS
DESCRIPTION
Fibroepithelial polyps are rare benign neoplasms. The majority of these polyps are found at the UPJ. Signs and symptoms usually associated with ureteral obstruction include flank pain and hematuria. In addition, varying degrees of hydronephrosis and ureteral intussusception have been described. Grossly, ureteral polyps are intraluminal lesions, most commonly covered with transitional epithelium. The bulk of the polyp is composed of vascularized collagenous fibrous tissue, with or without areas of chronic inflammation and edema. Ultrastructurally it is often necessary to confirm the diagnosis.

SYNONYMS
• Fibroepithyma
• Myxoma
• Fibroma
• Vascular fibrous polyps

TREATMENT
• Underscopic resection
• Open ureterotomy with polypectomy or partial ureterectomy is a reliable conservative treatment option if the diagnosis can be confirmed preoperatively.
• Many patients undergo nephroureterectomy for suspected malignancy.

REFERENCE

URETER, FISH HOOK (REVERSE J)
DESCRIPTION
A radiographic appearance of the type (fish hook) circumcaval ureter, in which the dilated proximal part of the ureter takes a characteristic fish hook or reverse J course. Universal dilatation usually ends 1–2 on lateral to the inferior vena cava, where the ureter turns upward at the border of the psoas muscle.

REFERENCE

URETER, HEMANGIOMA
DESCRIPTION
Hemangiomas are benign ureteral tumors. They may be the most common cause of chronic unilateral hematuria. Symptomatology may include hematuria, pain, hydroureter, bladder irritations, and palpable tumor. Venous lakes have also been found, but less frequently. Like other arterial tumors, hemangiomas usually cause incomplete obstruction and may eventually cause complete obstruction with dilation of the ureteral tract. They present as red, slightly elevated structures, fairly diffusely, and demarcated from their surroundings. Urethral malignancies must be excluded, especially in the elderly. Flexible ureteroscopy is considered a good diagnostic and therapeutic option in selected patients with unilateral hematuria of uncertain etiology.

REFERENCE

URETER, J HOOKING
DESCRIPTION
With progressive benign prostatic hypertrophy, elevation of the trigone occurs, resulting in a characteristic J hooking of the distal ureter. This is a reliable sign on IV of significant prostatic hypertrophy.

REFERENCE

URETER, LEIOMYOMA
DESCRIPTION
Leiomyomas of the urinary tract are rare (neoplasms of mesenchymal origin comprise <3% of all primary ureteral tumors). These benign tumors are seen predominately in the 4th–5th decade of life. The left ureter is more frequently affected. Immunohistochemical studies confirm the diagnosis. Conservative management (ureteroscopic or partial ureterectomy) is the treatment of choice.

REFERENCE

URETER, LEIOMYOSARCOMA
DESCRIPTION
Leiomyosarcoma originating from the ureter is exceedingly rare, with only 13 reported cases of primary leiomyosarcoma of the ureter. It is a disease that is very difficult to diagnose, and furthermore, it has a poor 5-year disease-specific survival. Patients present with flank pain, hematuria, and/or UTI. Radiographic workup includes IV, retrograde pyelography, and CT. Light microscopy, immunohistochemical staining and electron microscopy should be used to confirm the diagnosis of leiomyosarcoma.

TREATMENT
• Tumor resection
• Possible nephroureterectomy, depending on tumor grade and stage
• Adjunct radiation therapy may be helpful.

REFERENCE

URETER, METASTASIS TO
DESCRIPTION
Metastatic tumors of the ureter are uncommon, and 1 of the rarest causes of ureteric obstruction. Since their 1st mention in the literature in 1909 only ~400 cases are reported. Among 1/2 of the cases, the breast or gastrointestinal tract (colorectum) is the site for primary cancer. Prostate cancer and uterine cervical cancer are responsible for 35–40% of cases, with stomach and lung cancer being reported in the remaining cases. A prediction exists for the lower 1/3 of the ureter. Many are asymptomatic with the majority autopsy reports.

REFERENCE

URETER, NEPHROGENIC ADENOMA (NA)
DESCRIPTION
Nephrogenic adenoma (NA) is a rare neoplastic lesion of the ureter and assumed to be secondary to chronic irritation of the urethra. It is a benign papillary and tubular proliferation in response to trauma, infection, or limiting salivation. Although it can be seen anywhere in the urinary tract, it is most commonly observed in the bladder (55%). The incidence in ureter is ~4%. Biopsy and fulguration are appropriate, as it is treated as a low-grade urethral malignancy. Malignant transformation has not been described.

REFERENCE

URETER, NEUROFIBROMA
DESCRIPTION
Grossly, neurofibromas may be single or multiple and comprise different sized nodules. Histologically, they are composed of fascicles of elongated spindle-shaped cells with thin, wavy nuclei in a collagenized background. Neurofibromas in the ureter are very rare but have an increased incidence in von Recklinghausen disease.
A retrocaval ureter is a congenital anomaly in which the ureter passes behind the inferior vena cava (IVC). On IVP, the ureter appears straight with a narrow lumen, due to diffusely rigid changes of the wall. This results in secondary hydronephrosis.

**REFERENCE**

**URETER, PIPE-STEM**
Two types have been described. Type 1 is the more common where the ureter crosses anterior to the IVC at the level of the 3rd lumbar vertebra, and the degree of hydronephrosis is directly related to the level of the IVC. Type 2 retrocaval ureter is less common and the ureter tends to cross at a much higher level relative to the renal pelvis and the degree of hydronephrosis is usually mild. Treatment is surgery with transaction of the ureter and reanastomosis in front of the inferior vena cava. (See also Section I: “Ureter, Obstruction.”)

**REFERENCE**

**URETER, SHEPHERD’S CROOK**
Spirally twisted or “corkscrew” ureters are rare anomalies beyond the neonatal age. A spiraually twisted ureter is not considered clinically significant, unless it causes obstruction and secondary hydronephrosis. Infants frequently have a “corkscrew” appearance of the proximal segment of the ureter seen on intravenous urography, but this has been considered an imaging finding of no potential clinical significance. It may represent persistence of normal fetal developmental structures, such as congenital folds. Corkscrew configuration of the ureter may also be the result of ureteric varicosities or extrinsic ureteric obstruction when seen later in life. Obstructive uropathy is a serious clinical entity that may lead to irreversible renal damage. Corkscrew deformity of the ureter is a known cause of delayed recognition of uropathy secondary to bladder outlet obstruction (Image #).

**REFERENCE**

**URETER, STONE PASSAGE STATISTICS**
The ureter is the smallest diameter structure of the urinary tract. It is also the area most likely to be obstructed by a stone. Most stones <5 mm in diameter are likely to pass spontaneously with the likelihood of spontaneous stone passage decreasing with increased stone size. It is estimated that 2/3 of ureteral stones that pass spontaneously pass within 4 wk of the onset of symptoms.

**REFERENCE**
URETAL JETS
DESCRIPTION: Uretal jets have been studied to diagnose urethral obstruction. Uretal jets are visualized on color Doppler ultrasound as urethral urine passing into the bladder. Sensitivity of 100% and specificity of 90.9% in detecting urethral obstruction has been reported based on the absence of the urethral jet on a given side. Patients must be well hydrated and often when a prolonged imaging interval is needed to document the presence or absence of the urethral jet (Image 1).

URETAL STRICTURE FOLLOWING URINARY DIVERSION
DESCRIPTION: Urethral strictures are seen in 20–10% of patients who receive a cystotomy and urinary diversion for bladder cancer. The stricture is most commonly located at the ureterointerfacial anastomosis and more commonly involves the left ureter. Considered a late complication, strictures usually present in the 6–12 mo postoperative time period. Urethral recurrence of urethral carcinoma should be ruled out. Treatment includes percutaneous nephrostomy, indwelling ureteral stent, balloon dilation, or laser therapy.

URETERITIS
DESCRIPTION: A generic characterization given to describe inflammation of the ureter which can be further qualified into subtypes based loosely on its etiologic factors. For example, postobstructive, ureteral infections, ureteral strictures, infective or obstructive etiologies of ureteritis include ureteral amyloidosis, eosinophilic ureteritis, IgA associated ureteral inflammation, and idiopathic segmental ureteritis.

URETERITIS CYSTICA
DESCRIPTION: A benign and rare condition, ureteritis cystica is characterized by multiple cysts and space-filling defects in ureterum. Usually asymptomatic, it may present with hematuria, and if obstruction occurs, may lead to stone formation, UTI, and renal compromise. The etiology is unknown, but associated with chronic UTI. Space-filling defects seen on retrograde pyelography or excretory urography may appear as smooth, round or oval filling defects of varying sizes that protrude into the lumen. It can mimic other conditions such as bladder cancer, blood clots, air bubbles, radiolucent stones, fibroepithelial polyps, and sloughed renal papillae. It manifests as cystic areas of glandular metaplasia associated with chronic urethral inflammation; this is more commonly seen in the bladder, called cystitis cystica. Management is ureteroscopy and the mechanical disruption of cysts or infraction of chemicals such as silver nitrate to relieve obstruction.

URETERONECOSTOMYSTOSIS, TECHNIQUES AND INDICATIONS
DESCRIPTION: Ureteronecostomy, or ureteroneocystostomy, is used when there is an abnormality at the ureterovesical junction. Abnormalities include an obstructing ureteroureterostomy, ureteral reflux, distal ureteral stenosis, or urologic injuries. The surgical treatment options can be classified on the basis of the normal ureter to the bladder as intravesical, extravesical, or combined or on the relationship of the submucosal tunnel to the site of the original ureteral hiatus as suprahilar or infrahilar.

URETHRA, ADENOCARCINOMA OF ACCESSORY GLANDS
DESCRIPTION: In males, the accessory glands can develop adenocarcinoma. Adenocarcinoma of the seminal vesicles is distinct from adenocarcinoma of the epididymis. In females, the Skene glands can develop adenocarcinoma as well. Patients typically present with hematuria, dysuria, and progressive urethral obstruction. Management is similar to that for vesical adenocarcinoma. (See also Section II: “Cowper Gland Adenocarcinoma.”)

URETHRA, BLEEDING (BLOOD AT MEATUS)
SYNONYMS: Adenoma; villous polyp; hemorrhoids;
CAUSES: Posterior urethral (posterior and membranous urethra, proximal to urethral diaphragm)
PATHOPHYSIOLOGY: Prostatic-type polyps of the urethra
TREATMENT: Posterior urethral bleeding

URETHRA, BLEEDING (BLOOD AT MEATUS)
DESCRIPTION: Usually associated with GU trauma, blood at the urethral meatus is the single most important sign of urethral injury. Patients often complain of abdominal pain or inability to urinate, and report a history ofouch injury to the penis. Clinically, this finding is an absolute contraindication to immediate urethral catheter placement. Instead, urethrography should be performed (see below). This is distinct from idiopathic urethrorrhagia, which is bleeding from the urethra or blood spotting on the undergarments in preadolescents. Urethrorrhagia is a benign lesion and self-limited in most cases. (See also Section I: “Urethra, Trauma (Anterior and Posterior);” Section II: “Urethroitis, Hidradenitis.”
CAUSES:
1. Posterior urethral injury (posterior and membranous urethra, proximal to urethral diaphragm) associated with pelvic fracture and deceleration/shear injury
2. Anterior urethral injury (bulbous and pendulous urethral injury) associated with straddle injury and iatrogenic laceration
3. Traumatic urethral catheterization; more common in men
4. Neoplastic causes: idiopathic urethrorrhagia, malignancy (urethra, prostate, bladder), urethral carcinoma, urethral condyloma, urethral diverticulum, urethral stricture, benign prostatic bleeding, urethral hemangioma
TREATMENT:
1. In cases of urethral trauma, standard trauma management; shock and hemorrhage control
2. Avoid urethral catheterization
3. Retrograde urethrogram (12-Fr catheter in fossa navicularis) with 3 cc of iodine dye; retrograde injection of 20–30 cc of water-soluble dye to evaluate for extravasation beyond the urethra:
   - Positive extravasation: Immediate open bladder exploration with placement of suprapubic cystotomy tube; delayed urethral repair (3 mo after injury) with silicone urethral catheter placement concomitant with primary anastomosis
   - Negative extravasation: Careful urethral catheter placement; cystography

URETHRA, PROSTATIC TYPE POLyps
DESCRIPTION: Congenital, benign papillary-appearing lesions that occur most frequently in the prostatic urethra and contain benign prostatic epithelium. These have been reported in the anterior urethra. Cysts of the papillary projections contain prostatic stroma and glands. The lesions typically present in the 1st decade of life, but can appear at any age. Hemorrhage, erosion, and obstruction are common. Cystourethroscopy is usually diagnostic.
SYNONYMS: Urinary tract polyp; hemangioma
TREATMENT: Transurethral or suprapubic resection is curative.

URETHRA, PROSTATIC TYPE POLYPS
DESCRIPTION: Usually associated with GU trauma, blood at the urethral meatus is the single most important sign of urethral injury. Patients often complain of abdominal pain or inability to urinate, and report a history ofouch injury to the penis. Clinically, this finding is an absolute contraindication to immediate urethral catheter placement. Instead, urethrography should be performed (see below). This is distinct from idiopathic urethrorrhagia, which is bleeding from the urethra or blood spotting on the undergarments in preadolescents. Urethrorrhagia is a benign lesion and self-limited in most cases. (See also Section I: “Urethra, Trauma (Anterior and Posterior);” Section II: “Urethroitis, Hidradenitis.”
CAUSES:
1. Posterior urethral injury (posterior and membranous urethra, proximal to urethral diaphragm) associated with pelvic fracture and deceleration/shear injury
2. Anterior urethral injury (bulbous and pendulous urethral injury) associated with straddle injury and iatrogenic laceration
3. Traumatic urethral catheterization; more common in men
4. Neoplastic causes: idiopathic urethrorrhagia, malignancy (urethra, prostate, bladder), urethral carcinoma, urethral condyloma, urethral diverticulum, urethral stricture, benign prostatic bleeding, urethral hemangioma
TREATMENT:
1. In cases of urethral trauma, standard trauma management; shock and hemorrhage control
2. Avoid urethral catheterization
3. Retrograde urethrogram (12-Fr catheter in fossa navicularis) with 3 cc of iodine dye; retrograde injection of 20–30 cc of water-soluble dye to evaluate for extravasation beyond the urethra:
   - Positive extravasation: Immediate open bladder exploration with placement of suprapubic cystotomy tube; delayed urethral repair (3 mo after injury) with silicone urethral catheter placement concomitant with primary anastomosis
   - Negative extravasation: Careful urethral catheter placement; cystography

URETHRA, PROSTATIC TYPE POLYPS
DESCRIPTION: Congenital, benign papillary-appearing lesions that occur most frequently in the prostatic urethra and contain benign prostatic epithelium. These have been reported in the anterior urethra. Cysts of the papillary projections contain prostatic stroma and glands. The lesions typically present in the 1st decade of life, but can appear at any age. Hemorrhage, erosion, and obstruction are common. Cystourethroscopy is usually diagnostic.
SYNONYMS: Urinary tract polyp; hemangioma
TREATMENT: Transurethral or suprapubic resection is curative.
Carcinoma of the urethra is a rare neoplasm arising from the transitional epithelium of the urethra. It is a mixed tumor of both mesenchymal and epithelial elements. The majority of cases occur in females, with a peak age of 30–40 yr. For women, the disease is hormonally associated and many of these tumors enlarge in pregnancy. Treatment is local excision, and in most cases, there is no local recurrence. A small subset of cases may present as a mixed tumor with both adenocarcinomatous and leiomyomatous components. This type of tumor has been associated with prolonged use of azo-alpha blockers for benign prostatic hyperplasia.

**REFERENCES**

URETHRA, DIVERTICULUM

**DESCRIPTION**
Urethral diverticula are rare pathologic entities commonly found in females, with an average age at presentation of 52. Reported symptoms include urethral bleeding (most common), dysuria, genital mass, and urethral obstruction. Adenocarcinoma occurs more frequently in transitional and squamous cell cancers combined and carries a more favorable prognosis. Female urethral diverticulum can be diagnosed through MR imaging with a high index of suspicion in patients with recurrent UTIs, dysuria, urgency, and pelvic dribbling. (See Section I: “Urethra Diverticula, Female,” “Urethra, Carcinoma, General.”)

**TECHNIQUES**
- Surgical: Radical cystourethrectomy with pelvic node dissection is recommended by most authors.
- Diverticulectomy has been suggested for low-stage adenocarcinoma, if close follow-up is assured.

**REFERENCES**

URETHRA, FOREIGN BODY

**DESCRIPTION**
Cases of self-inflicted foreign body insertion in males have been reported, including objects such as fishhooks, bones, screws, safety pins, and light bulbs. Cause for inserting foreign bodies varies, including psychopathic disorder, intoxication, and erotic stimulation. Endoscopic retrieval is usually successful using modern instruments. Open surgery may also be considered. IV perioperative antibiotics followed by PO antibiotics for 1 wk has been recommended. Delayed complications include structure disease, therefore close urologic follow-up is recommended (Image 05).

**REFERENCES**

URETHRA, HEMANGIOMA

**DESCRIPTION**
Urethral hemangiomas are extremely rare tumors. The lesion is believed to be congenital, arising from the embryonic rests of unipotent angioblastic cells that fail to develop into normal blood vessels. The clinical presentation is bloody urethral discharge or frank urethral bleeding. These lesions are benign in nature. They are treated by local resection or ablation with electrocoagulation or laser. (See also Section I: “Urethra, Bleeding [Blood at Urination].”)

**REFERENCES**

URETHRA, LEIOMYOMA

**DESCRIPTION**
Rare benign neoplasm arising from smooth muscle. The majority occur in females, with a peak age of 30–40 yr. It usually presents as an asymptomatic mass, or with dysuria, UTI or obstruction, and dyspareunia. The proximal urethra is most commonly involved. No etiology is known, but it is hormonally associated and many of these tumors enlarge in pregnancy. Treatment is local excision, and prognosis is excellent as no malignant transformation or local recurrence has been reported in the literature. (See also Section I: “Urethral Mass.”)

**REFERENCES**
URETHRA, LEIOMYOSARCOMA

DESCRIPTION: Leiomyosarcoma is a smooth muscle tumor that often involves the urinary tract. Leiomyosarcomas are extremely rare tumors that are more common in females than in males. Patients present with hematuria, pain, or mass. The prognosis is poor, and the treatment is radical excision with consideration of adjuvant radiation. (See also Section I: “Urethra, Mass.”)

URETHRA, LEUKOPLAKIA

DESCRIPTION: The term leukoplakia (also called squamous metaplasia) refers to the presence of grossly discernible white patches commonly seen on the mucosal surfaces of areas of squamous metaplasia. There seems to be an increased incidence in patients with diabetes, as well as in those with chronic irritation or infection. Generally believed to be a premalignant lesion caused by chronic infection or irritation, it may progress to squamous cell carcinoma. (See also Section II: “Leukoplakia.”)

URETHRA, LYMPHOMA

DESCRIPTION: Primary malignant lymphoma (PML) of the male urethra is an extremely rare neoplasm. (See also Section I: “Urethra, Mass.”)

URETHRA, LYMPHOMA

DESCRIPTION: Primary malignant lymphoma of the male urethra is an extremely rare neoplasm. (See also Section I: “Urethra, Mass.”)

URETHRA, MALACOPLAKIA

DESCRIPTION: Malacoplakia is a chronic inflammatory disorder characterized by the presence of Michaelis–Gutmann bodies and von Hansemann cells. The disease shows a predilection for involving the mucosal surfaces of areas of squamous metaplasia. There seems to be an increased incidence in patients with diabetes, as well as in those with chronic irritation or infection. Generally believed to be a premalignant lesion caused by chronic infection or irritation, it may progress to squamous cell carcinoma. (See also Section II: “Leukoplakia.”)

URETHRA, MALIGNANT MELANOMA

DESCRIPTION: Primary urinvasive malignant melanoma is rare, with <100 cases reported in the literature. 90% of patients are diagnosed in the 6th–7th decades. 80% of cases were reported to be in the fossa navicularis and the meatus. The most common presentations are dysuria, hematuria, deviated urinary stream, or urinary obstruction. Endoscopically, a pigmented nodular mucosal mass or masses, which may be ulcerated, may be seen. Local recurrence is common. Metastasis is usually to regional lymph nodes or liver, lung, and brain is also common. Staging for urothelial melanoma has not yet been standardized. Prognosis depends on the thickness of the lesion.

TREATMENT:
- Surgery: Excision of the lesion
- Chemotherapy
- Radiation therapy
- Immunotherapy
- Targeted therapy

URETHRA, POLYPS (FIBROEPITHELIAL, ADENOMATOUS, INFLAMMATORY)

DESCRIPTION

Uncertain benign polypoid of papillary lesions of the urethra, these are usually limited to male patients and occur most often in children. Polyps vary in microscopic features, which result in their classification into fibroepithelial, adenomatous, or inflammatory. Adenomatous polyps are thought to represent prostatic glandular material from a congenital developmental error. A fibroepithelial polyp consists of connective tissue inflammation, inflammatory polyps have a distinct inflammatory infiltrate. Presenting symptoms can include hematuria, hematospermia, obstruction, or UTI. Cystourethroscopy with biopsy is the test of choice. Transurethral resection with fulguration is the treatment of choice, along with removal of the source of inflammatory cells, catheter or stone removal if present. (See Section II: “Urethra, Polypoid and Polyoid.”) “Urethritis, Polypoïd.”

URETHRA, PROLAPSE (FEMALE)

DESCRIPTION

Prolapse of the urethra is a rare condition, described as complete eversion of urethral mucosa through the external urethral orifice; the etiology is unknown. It is primarily associated with prepubertal girls and postmenopausal women with African-American girls more commonly affected. Vaginal bleeding is often the presenting symptom, followed by urinary complications such as dysuria. Associated factors include increased abdominal pressure, such as coughing or constipation, and trauma or infections of the vagina or urinary tract. Management ranges from conservative medical treatment to a variety of surgical corrective procedures, such as excision and urethropexy. Medical treatment includes local hygiene, sitz bath, topical antibiotics, or topical estrogen creams (adults). Surgical intervention is indicated for more severe cases, including significant bleeding, thrombosis, or gangrenous changes or if topical estrogen is contraindicated. Surgical treatment is usually accomplished with the modified Kelly–human operation. The prolapsed mucosa is excised, and the mucocutaneous junction is reaproximated with absorbable sutures.

REFERENCES

URETHRA, VILLOUS ADENOMA

DESCRIPTION

An adenomatous lesion of the urethra, usually polypoid in nature, covered by mucinous material. Masses as large as 2–4 cm in the urinary tract have been described. Etiology is possibly due to an embryonic origin similar to that of the rectosigmoid. Urinary obstruction and/or hematuria can be presenting symptoms. Best treated by complete removal, due to the premalignant changes seen in adenomas of the colon. These lesions are most commonly encountered in the male prostatic urethra. Histogenesis has been suggested to be secondary to residual cloacal epithelium in the prostatic urethra.

REFERENCES

URETHRAL HYPERMOBILITY

DESCRIPTION

Also called type II stress urinary incontinence (SUI), urethral hypermobility is caused by weak support of pelvic floor supporting structures, in which increased intra-abdominal pressure causes the descent of the bladder neck and proximal urethra. Women with hypermobility present with SUI, although some continent women have it as well. The degree of hypermobility is measured by the Q-tip test, in which a well-fabricated sterile cotton tipped applicator is placed into the bladder and then withdrawn to the point of resistance. The patient is then asked to strain and the motion of the Q-tip is observed. Hypermobility is defined as a rotating or straining angle 30% from horizontal. Treatment is per urethral collagen injection or suburethral slinging procedure.

REFERENCE

URETHRAL PRESSURE PROFILE (UPP)

DESCRIPTION

The UPP is a graphic representation of the intravesical pressure along the length of the urethra. This static study provides no assessment of physiologic urethral function during voiding. The mucosal urethral pressure profile, however, is a dynamic study that can be performed by withdrawing a catheter from the urethra during micturition. The study can define the site of urethral obstruction by demonstrating a drop in urethral pressure immediately distal to the obstructive lesion in the urethra. Controversy exists on its use in clinical practice due to the variability in the reproduction of measurements and lack of standardization.

REFERENCES

URETHRAL SLING, INDICATIONS AND ANATOMIC POSITIONS

DESCRIPTION

A urethral sling is a surgically placed to support pelvic structures or lift the urethra to enhance the bladder and pelvic floor’s ability to retain urine in patients with stress urinary incontinence (SUI). Slings can be made from autologous, alloplast, xenogenic, or synthetic tissues that provide strength. They can be placed at the proximal urethra (pubovaginal sling) or mid urethra (transvaginal tape [TVT] and transobturator [TOT] and other mid urinary slings). The urethral sling is a very effective treatment for SUI, with cure rates of 80–95% vs. other options such as the per urethral injection of bulking agents. Complications include erosion into surrounding structures such as vagina, urethra, and bladder, as well as bladder perforation, urinary tract infection, and new onset irritative voiding symptoms. (See also Section I: “Incontinence, Urinary, Adult Female”, Section II: “Sling Materials.”)

REFERENCES

URETHRAL SLING, STRUCTURE, FEMALE

DESCRIPTION

A decrease in the caliber of the urethra, as in females compared with males. Causes can include recurrent UTIs, previous endoscopic instrumentation, surgical management of urethral pathology or diverticular repair, trauma (including childbirth), neoplasia, or pelvic radiation, or it can be idiopathic. The patient usually presents with recurrent UTI or obstructive urinary symptoms (weak stream, straining to urinate, incomplete emptying). Female urethral structure has been formally defined as a fixed anatomic narrowing between the bladder neck and distal urethra of < 14 Fr preventing catheterization, with the diagnosis confirmed by cystourethroscopy, and/or videourodynamics. Interim catheterization has been used successfully, with internal urethrotomy or urethropexy also as options.

URETHRAL SYNDROME

DESCRIPTION

A nonspecific term used in the past to describe symptoms such as urinary frequency, urgency, dysuria, and pelvic/perineal discomfort having no obvious cause. Because this term is so nonspecific, it is not meaningful for diagnosis or treatment planning. A more effective approach is to delineate each of the patient’s specific symptoms (e.g., frequent voiding), then pursue the differential
Chronic urethritis is a common

Centers for Disease Control and Prevention. Sexually

TREATMENT

chlamydia. Syphilis, HIV, and hepatitis B serology is

>5 WBC/HFP strongly suggests urethritis. Intraurethral

granular areas are often seen, and polyoidal masses are common. The symptoms resemble those of cystitis, although the urine is not infected. Complaints include dysuria, frequency, and nocturia. Discomfort in the urethra may be felt, particularly when walking. Urethral dilatations may help if steroids is found obsolete to 38 Ks. Empiric doxycycline or azithromycin can be tried.

REFERENCE

Urethral stricture or pelvic inflammatory disease (PID) in women, may ensue. Cause is predominantly N. gonorrhoeae and C. trachomatis infection; often together. Less common infectious agents include Ureaplasma urealyticum, Trichomonas vaginalis, herpesvirus, and Mycoplasma genitalium. Noninfectious causes include foreign bodies, soaps, douches, spermidides, and urethral instrumentation. Gram stain of discharge with >5 WBC/HFP strongly suggests urethritis. Intraurethral gram-negative diplococci are strongly indicative of gonorrhea. Cultures may be difficult to obtain, but are important for antiretroviral sensitivity testing and should be performed in all symptomatic patients. Routine urine analysis may be normal in simple urethritis. Tox and urine is often positive for leukocyte esterase and should show >5 WBC/HFP in acute urethritis. IFAF utilizing PCR assay on urine is very sensitive and specific, but costly. Wet prep of discharge may reveal Trichomonas; this is usually reserved in males who fail adequate treatment for gonorrhea and chlamydia. Syphils, HIV, and hepatitis B serology is performed as indicated to rule-out concomitant 3Ts.

TREATMENT

The United States Preventative Services Task Force recommends: screening all sexually active women >25 yo and all other women at increased risk of infection:

• All sexual partners who come in contact with the patient within 60 days should be evaluated, treated, and treated for gonorrhea and chlamydia.

• Gonorrhea Ceftriaxone 250 mg in a single IM PLUS Azithromycin 1 g orally in a single dose or doxycycline 100 mg orally twice daily for 7 days.

• Chlamydia: Azithromycin 1 g PO single dose or doxycycline 100 mg orally twice daily for 7 days.

• Trichonomiasis: Metronidazole 2 g PO single dose or 250 mg TID for 7 days or tinidazole 2 g PO in a single dose.

REFERENCE

URETHRITIS, CHRONIC, FEMALE

DESCRIPTION Chronic urethritis is a common urologic problem of females, as the distal urethra normally harbors pathogens. Infection may be increased by wearing contaminated diapers, by insertion of an introducer catheter, by spread from

can be felt, particularly when walking. Urethral dilatations may help if steroids is found obsolete to 38 Ks. Empiric doxycycline or azithromycin can be tried.

REFERENCE

URETHRITIS, POOLYPOID

DESCRIPTION A urethral counterpart of polypoid cystitis, occurs as single or multiple polypoid/ papillary lesions. A noninflammatory inflammatory lesion that is usually found in the prostatic urethra near the verumontanum. The lesions are edematous stroma with distended blood vessels and chronic inflammatory infiltrate. Usually resolves after removal of the inflammatory stimulus; if necessary, resection of the lesion usually leads to a cure. If the lesion persist, malignancy should be ruled out.

REFERENCE

URETHRITIS, SENILE

DESCRIPTION After physiologic (or surgical) menopause, hypoestrogen occurs and retroperitoneal (senile) changes take place in the vaginal (atrophy) and the urethral walls. Some evasion of the mucus at the urethral orifice, from atrophy of the vaginal wall, is usually seen and can be misdiagnosed as a cancer. Many postmenopausal women have symptoms of vesical instability (burning, frequency, urgency) and stress incontinence. Oxyuria may occur due to urine contact with the inflated atrophic tissues themselves or because of the increased incidence of UIs in these women. Best treated symptomatically or with DES vaginal suppressions 0.1 mg nightly for 3 wk. The patient may also benefit from other topical agents such as estral vaginal tablets or from conjugated estrogen cream or slow release intravaginal therapy such as the Estring.

REFERENCES

URETHROCELE

DESCRIPTION Urethroccele is a form of pelvic prolapse in which the urethra protrudes into the anterior wall of the vagina, due to loss of the normal urethral support from damage such as childbirth. Cystocele is also commonly present. In women, a urethroccele can cause voiding difficulty, some degree of incontinence, UI, and dyspareunia. The condition can also develop in children after urethralplasty, with distal obstruction causing proximal dilution of the neourethra; it is very rarely congenital. (See also Section 1, "Vulvo Vaginal [Gynecologic and Obstetric]").

REFERENCE

URETHROHETRAGIA, DIOPHATIC

DESCRIPTION Bleeding from the urethra or blood spotting on the underwear is prevalent in average age (around 10 y) is a benign condition, self-limiting in most cases. The etiology is unknown. Routine radiographic, lab, and endoscopic evaluation is unnecessary for evaluating urethrophy. Watchful waiting is indicated, as the condition resolves in 71% and 91.7% of patients at 1 and 2 y, respectively. Evaluation should be considered in patients with prolonged urethrophy because urethral fracture may be identified. (See also Section 8.1. "Urethral Bleeding [Bladder at Meatus]."

REFERENCE

URETHRAL INCONTINENCE/URETHRAL URINARY INCONTINENCE (UIU)

DESCRIPTION Urethral urinary incontinence (UI) is the involuntary leakage of urine immediately preceded by a sense of urgency. It is caused by detrusor muscle overactivity. Etiology is categorized into idiopathic; neurogenic, including stroke, diabetes, and other causes; or nonneurogenic, including infections, bladder stones, and cancer. Initial workup includes a good history and physical, evaluation for other associated urinary symptoms, check of postural residual, urine analysis. Cystoscopy should be performed in the setting of simultaneous hematuria. Urodynamie evaluation can be considered medically refractory patients. (See also Section 1. "Incontinence, Female” and “Urinary Incontinence, Male”)

TREATMENT

• Symptomatic control mainstay of treatment.

• Dietary and behavioral modifications: Limiting caffeine-containing foods, alcoholic beverages, and foods rich in vitamin A and vitamin E. Avoid wearing tight-fitting clothing.

• Biofeedback-assisted pelvic muscle training

• 1st-line medical therapy: Anticholinergics, β3 agonists

• 2nd-line therapy: Intravesical Botulinum toxin, sacral neuromodulation, and augmentation cystoplasty.

URGE INCONTINENCE/URGEO URINARY INCONTINENCE (UI)

DESCRIPTION Urge urinary incontinence (UI) is the involuntary leakage of urine immediately preceded by a sense of urgency. It is caused by detrusor muscle overactivity. Etiology is categorized into idiopathic; neurogenic, including stroke, diabetes, and other causes; or nonneurogenic, including infections, bladder stones, and cancer. URINARY FLOW RATE (EUROFLOWMETRY)

DESCRIPTION

Uroflowmetry is the study of urinary flow rate (Qmax). The Qmax is defined as the product of maximum bladder capacity times the maximum flow rate. It is not a diagnostic test, but a test of bladder function. An abnormality that these patients undergo periodic colonoscopy to accurately define any morbidities from their previous diversion.

REFERENCES

URINARY DIVERSION, RISK OF MALIGNANCY

DESCRIPTION

Symptoms of bowel used for urinary diversion have an increased risk of malignant transformation. Some studies have shown an increase in 5% to as high as 40% 10–20 yr after a urinary diversion. The etiology is unknown; adenocarcinomas, adenomatous polyps, sarcomas, TCCs, signet ring carcinomas, and ESCCs have been identified. Many investigators now recommend annual screening in patients who have intestinal segments in contact with urine beginning 10 yr after the initial surgery. Patients who have previously undergone a nephroureterectomy are at particular increased risk for development of adenocarcinoma of the sigmoid colon along the anastomotic line. It is recommended that these patients undergo periodic colonoscopy to accurately define any morbidities from their previous diversion.

URINARY TRACT INFECTION (UTI), CATHERETER-RELATED (CAUTI, CA-UTI)

DESCRIPTION: UTI is the most common hospital-acquired infection in the United States and a major focus to improve patient outcomes. Any passage of a urithal catheter can introduce bacteria into the bladder. Once the catheter is in place, bacteria enter the bladder around the catheter (extraluminal infection) and from intraluminal infection failure of closed drainage or contamination of the urine collection bag. The incidence of bacteriuria in patients with indwelling bladder catheters is directly related to the duration of catheterization. Even with optimal bladder care, 3-10% develop significant bacteriuria daily. Of these patients, 10-35% develop symptomatic UTI (catheter associated UTI or abacteriuric CAUTI), and 4% may develop bacteremia. Avoiding unnecessary catheterization, remissimg the catheter as soon as possible, and appropriate catheter management (closed catheter drainage) are the most effective methods to reduce these infections. Silver-coated urinary catheters have been shown to reduce infections. Patients who require long-term bladder drainage should be managed with intermittent catheterization, if possible. This approach is associated with a lower rate of bacteriuria and CAUTI than management with long-term indwelling catheterism. Prophylactic antibiotics are not consistently of proven benefit. Catheter-associated urinary tract infection definitions by the CDC have recently been narrowed to exclude asymptomatic bacteriuria. (See also Section E: “Urinary Tract Infection (UTI), Catheter Associated (CAUTI, CA-UTI).”)

URINE, ABNORMAL COLOR

DESCRIPTION: Normal urine is clear and pale to yellowish, but urine colors can be caused by disease, medications, and dietary factors. Other factors that may affect urine color include lighting conditions and environmental factors such as humidity and air pollution. Changes in urine color can also be caused by certain medical conditions, such as kidney disease, liver disease, or cancer. (See also Section IX: “Urinalysis.”)

COLORS OF URINE

Light yellow: Normal color of urine, seen in the morning after a night of sleep, when the body is in a state of hydration.

Deep yellow: Possible signs of dehydration or kidney disease. (See also Section IX: “Urinalysis.”)

Green: May indicate a problem with the urinary tract, such as infection or stones. (See also Section IX: “Urinalysis.”)

Red: May indicate blood in the urine, such as from a kidney stone or bladder infection. (See also Section IX: “Urinalysis.”)

Black: May indicate kidney disease, liver disease, or exposure to certain medications. (See also Section IX: “Urinalysis.”)

URINE, FOAMING

DESCRIPTION: Foaming urine is a clinical finding often associated with proteinuria and kidney disease and its observation dates back to Hippocrates. Increasing degrees of proteinuria produce decreasing degrees of surface tension. In addition, the elliptical shape of protein molecules at the air-water interface produces increased surface activity. These factors exacerbate the environment in which molecules are unable to remain in a monolayer due to electrostatic repulsion; this produces foam. Occasionally, foaming is transient and caused by a focal urination into water in a toilet. (See also Section IX: “Urinalysis and Urinary Studies.”)

TREATMENT

• Treat the underlying cause of proteinuria

• Qualitative dipstick analysis; 24-hr urine collection, renal workup

REFERENCES

URINE, ODOR

DESCRIPTION

Urinary odor is related to the volume, concentration, and composition of a variety of secreted chemicals and physiological contributions from the urinary system. Normally, urine ranges from odorless to mildly aromatic, often described as fruity or “urinous.” Changes in odor are often temporary and carry little prognostic indication; however, medical conditions can occasionally present with distinct urinary odors, as described below. (See also Section IV: “Urine Studies.”)

Condition Urine Odor

Diseases
Cystine decarboxylation, cystinuria
Sulfured
Dehydration
Strong
Diabetic ketoacidosis

URINE, PARTICLES IN DESCRIPTION

In the gross observation of particulate matter in the urine, differential diagnoses include infection (bacteria, fungi), enterocecal fistula (meso, fores, or undigested food particles), blood clots from hematuria of any cause, papillary necrosis, ATN, thyrotoxicosis, crystalluria, bilirubinuria (cholethrombosis), urinal or other carcinoma with sloughing tissue, clumping of excessive urinary cast or protein, postextensive ileg (i.e., ureteral material), or vaginal contamination. The condition can be a normal finding with any form of urinary diversion that uses a bowel segment (usually mucous or sloughed epithelium). Note that a urine sample left standing at room temperature may cause precipitation of phosphate salts. Urine samples that will not be analyzed immediately (<2 h) should be refrigerated. Curing of the specimen after addition of a small amount of acid indicates that precipitation of salts is the probable cause. (See also Section II: “Infectious.”)

REFERENCE

URINOMA (PERINEPHRIC PSEUDOCYST)

DESCRIPTION

A collection of urine outside the urinary tract (extravesical), commonly seen from rupture of the collecting system (usually calyceal rupture) due to high pressures from obstruction (stones, posterior urethral valves, stricture, others), postoperative surgical leak (lumbar anastomosis, collecting system issues, urethral anastomosis, etc.), or traumatic disruption of the urinary tract (iatrogenic, penetrating, or blunt). Leakage of urine into the perirenal or perinephric tissues in excess of an amount that can be absorbed results in urinoma formation. The urine causes lipolysis of surrounding fat, creating a fibrous sac around the extravasated urine. Perinephric pseudocyst is the term sometimes used for an urinoma that surrounds the kidney. The urinoma fluid’s creatinine level is typically elevated, indicating urine as the source. Urinoma must be distinguished from hematoma, abscess, or collections. Classically, the urinoma is thin-walled and smooth, and the walls tend to enhance secondary to inflammatory neoangiogenesis. In contrast, the walls of abscesses and hematomas tend to be thick and more irregular with even more prominent vascularity. Typically, urinomas demonstrate homogeneous. Hounsfield units between –10 and +30 HU, and hematomas and abscesses demonstrate heterogeneous Hounsfield units. Treatment is directed at correcting the cause (relief of obstruction, stenting, or repair of leak). Small urinomas will resolve spontaneously, and drainage is not necessary. If the urinoma is large, CT or MRI-guided drainage or aspiration can be performed in perineal urinomas due to trauma to the kidney, viability of the parenchyma must be assessed by contrast-enhanced CT. If no viable tissue components extend to the collecting system (suggestive of necrosis), there is an increased risk for continued urine leak and debridement is necessary. (See also Section I: “Renal Trauma,” AATB, and Image 40.)

REFERENCE

URINOTRACHIS

DESCRIPTION

Urinotrichus is rare and refers to the presence of urine in the pleural space. It usually occurs secondary to obstructive uropathy, from the leakage of urine into a perirenal or perinephric urinoma and then its passage into the pleural space directly or via lymphatics. Cases have been reported in the setting of interventions including percutaneous nephrostomy, ESWL, and others. It is classified as a transudate. The diagnosis can be confirmed by finding a pleural fluid-to-serum creatinine ratio >1 (often >10). Relief of obstruction causing the persisting urine leak and thoracoscopy or chest tube placement is therapeutic.

REFERENCE

URODYNAMICS, INDICATIONS AND NORMAL VALUES

DESCRIPTION

A series of investigational tests to assess lower urinary tract function. Usual components include uroflowmetry, cystometry, abdominal pressure monitoring, electromyography, and voiding pressure–flow studies. Through simultaneous measurement of bladder and abdominal pressures, the detrusor pressure can be inferred and used to interpret neuromuscular events during voiding. UOS can be used to identify contributing factors to voiding dysfunction and assess their relevance, predict consequences of that dysfunction on the upper tracts, to predict the consequences and outcomes of therapeutic intervention, to confirm or understand the effects of interventional techniques, and to investigate the reasons for treatment failure. See table for Normal UOS values in Adults (Image 60).

Common urodynamics Indications Include:

• Failure of empiric treatments
• Symptomatic voiding dysfunction prior to beginning incontinence therapy
• Inability to demonstrate incontinence clinically despite subjective patient complaints
• Significantly or obviously of proposed incontinence treatment course:
• Following prior surgical therapy for incontinence, following pelvic radiation or radical pelvic surgery
• Known or suspected neurologic disorder that may influence bladder function (i.e., spinal cord injury)
• Simpler diagnostic tests have been inconclusive

Normal UOS values in Adults:

• Volume Voids (ml): 338 ± 214
• Voiding Time (sec): 28 ± 22
• Max Flow (ml/sec): M 34 ± 10, W 30 ± 10
• Average Flow (ml/sec): M 14 ± 5, W 22 ± 14
• Maximum Capacity (ml): M 552 ± 152, W 453 ± 146
• Compliance (ml/cm water): M 56 ± 37, W 71 ± 40
• Postvoid Residual (ml): ≥ 20 ± 50

M: men; W: women.

REFERENCES

UROLITHIASIS, METHOTREXATE

DESCRIPTION
Methotrexate is an anti-folate used to treat a wide variety of diseases including: Cancer, rheumatoid arthritis, lupus, ectopic pregnancy, and psoriasis. More than 90% of the drug is cleared in the urine. Drug and its metabolites are poorly soluble in acidic pH and can precipitate crystalline formation and subsequent tubular obstruction. Medication can also lead to an increase in uric acid levels in the body. Extreme care with only a few reports of renal calculi to the FDA from using this medication. [See also Section I: “Urolithiasis, Adult General” and Section II: “Urolithiasis, Drug Induced.”]

TREATMENT
• Urine alkalinization
• Hydration to induce high urine flow rates

UROLITHIASIS, MELAMINE

DESCRIPTION
An increased incidence of kidney stones and renal failure recently reported in China are believed to be associated with ingestion of infant formula contaminated with melamine. Melamine (triaminocyanurate, melamine) has industrial use as a resin or adhesive, and has been deliberately added to casein milk to boost its protein content. Although the mechanism is not clear, melamine is almost completely excreted by the kidney and appears to interact with uric acid (to be produced or associated impurity) to form crystals. Low solubility promotes precipitation in renal tubules and causes progressive blockage and significant renal degeneration.

TREATMENT
• Immediately discontinue use of melamine containing food products.
• Medically monitor renal function, fluid balance, and electrolyte status.
• Alkalize the urine.
• Treat acute kidney injury (AKI if indicated) use blood or peritoneal dialysis.
• Consider surgical pyelolithotomy in refractory cases.

UROLITHIASIS, INFECTIOUS (STRUVITE)

DESCRIPTION
Composite of magnesium, ammonium, and phosphate mixed with carbonate. Struvite stones directly correlate with the presence of urinary-producing bacteria and active UTI. Associated with a urinary pH of >7.2, which causes struvite crystallization. They usually undergo rapid growth and may result in replacement of the entire pelvis with a stone. (See also Section II: “Urolithiasis, Drug Induced.”)

CAUSES
• Foreign body in the urinary tract
• Neurogenic bladder
• Urinary diversion
• URTs
• Indwelling catheter

REFERENCE

UROLITHIASIS, MATRIX

DESCRIPTION
Also called matrix stone, matrix nephrolithiasis, or matrix calculus in the literature, this rare renal calculus has been described as being composed of coagulated mucoids with little crystalline component. Found mostly in individuals with infection due to urease-producing organisms such as Proteus, matrix calculus can be confused with uric acid calculi because they are radiopaque. Matrix calculus, however, are usually associated with alkaline urine from a U/I, whereas uric acid calculi usually form in acidic sterile urine. Standard treatment techniques such as ureteroscopy and lithotripsy are used. (See also Section I: “Urolithiasis, Adult General”)

VAGINAL DISCHARGE, UROLOGIC CONSIDERATIONS
DESCRIPTION
Fluid flowing from the vaginal opening, which can be physiologic or pathologic. Timing, color, consistency, odor, and associated symptoms are all important aspects of the evaluation. (See also Section I: “Vaginitis/vulvovaginitis” and Section III: “Vaginal Discharge Algorithm.”)

CAUSES
• Noninfective: Physiologic uterine sloughing, cervical ectopy, retained foreign bodies (eg, tampon), vulval dermatitis, urethral diverticulum, sexual abuse
• Noninfectively transmitted: Bacterial vaginosis, candida infection
• Sexually transmitted infection: C. trachomatis, N. gonorrhoeae, other gonococcal vaginitis (Image 40)

REFERENCES

VAGINAL DUPLICATION
DESCRIPTION
A rare abnormality in embryologic development that results in duplication of the vagina. It is caused by failure of a primitive septum in the urovesical canal to regress or by abnormalities in the fusion of paraxial mesenchymic ducts during wk 6–9 of embryologic development of the upper vagina. The lower vagina develops from the urogenital sinus when the urovesical bulbs fuse. Abnormalities in the fusion can result in different vaginal abnormalities, including duplication. Presenting symptoms can include dysmenorrhea at menarche or a lower abdominal mass. Surgical correction of the septum is the treatment of choice for vaginal duplication.

REFERENCES
VAGINAL FUSION

DESCRIPTION
A congenital defect of the vagina may occur if the fusion of the labia minora is incomplete. This is often observed as a small opening at the external os of the cervix. Surgery is usually required to repair the defect.

REFERENCE

VAGINAL MASS, NEWBORN

DESCRIPTION
Rare intravaginal or perineal lesions are found in young girls, each with strikingly similar gross appearances; among the different etiologies listed below. Clinical exam should note exact location of lesion, urethral location, and urine flow. Workup depends on exam, although voiding cystourethrography is usually warranted.

CAUSES
- Hydroepidermis (separate hymen)
- Paracolpial cyst
- Prolapsed ectopic uretercele
- Rhombomeroepithelium of the vagina
- Urethral polyp
- Urethral prolapse

REFERENCE

VAGINAL PESSARIES, UROLOGIC CONSIDERATIONS

DESCRIPTION
A pessary intravaginal device is used to maintain the correct anatomic position of the pelvic organs and aid in urinary continence. The overall prevalence of incontinence in individuals >65 is ~30%. Pessaries provide a noninvasive management option for that subset of patients with stress urinary incontinence (SUI). Despite a wide range in published results, when combined with pelvic floor muscle rehabilitation (ie, Kegel exercise, biofeedback), pessary use may improve symptoms 50-75% of the time. This may be used as a final treatment in patients at high operative risk, or as a bridge to surgical correction of pelvic floor dysfunction.

REFERENCE

VAGINAL PROLAPSE

DESCRIPTION
Disruption of the neuromuscular, fascial, or fascial components involved in normal vaginal support, resulting in the externalization of a portion of the vaginal canal. Despite a complex anatomic framework, several key anatomic anomalies may play a role in this condition. As well, theologic anomalies are associated with inguinopelvic and femoroanterior associations in children. Posterior surgery involves the use of the posterior vaginal wall, while anterior surgery involves the anterior vaginal wall. Patients may report symptoms of stress urinary incontinence or low back pain. Diagnosis is made by examination, with further imaging as needed. The patient may be treated with a pessary, or as an acute measure, with pelvic floor muscle rehabilitation. Treatment options include: sling, mesh, and vaginal repair. The choice of treatment should be individualized, with consideration of patient age, parity, and comorbidities.

REFERENCE

VAGINOSIS

DESCRIPTION
The most common type of vaginal infection, resulting from an imbalance between the standard vaginal flora (Lactobacillus spp.) and the pessaries of the body. Many different types of pathogens have been identified, including Streptococcus, Enterococcus, and Mycoplasma. Symptoms include a foul or “fishy” odor, milky white or gray discharge, and vaginal irritation especially prominent after sex. Diagnosis can be confirmed by elevated vaginal pH (>4.5), a positive “whiff test” malodorous/fishy odor when secretions are mixed with 10% potassium hydroxide. Successful treatment is associated with restoration of normal vaginal flora and subsequent improvement in symptoms.

REFERENCE

VALSALVA MANEUVER

DESCRIPTION
A maneuver affected by a forced expiratory effort against a voluntarily closed airway, which causes increased intrathoracic and intra-abdominal pressure and impairs venous return to the right atrium. The maneuver may increase the risk of either avulsion or ureteral injury during surgical correction (11%) and postoperative association with 3% mortality. The pelvic anatomy is restored. (See also Section I: “Pelvic Prolapse” (Cystocele and Enterocele).)

- Cystocele (bladder into vagina)
- Enterocele (small intestine into vagina)
- Rectocele (rectum into vagina)
- Urethrocele (urethra into vagina)
- Uterine prolapse (uterus into vagina)
- Vaginal vault prolapse (vaginal roof through vaginal)

TREATMENT
- Abdominal sacrocolpopexy: Anterior and posterior grafts bridging vaginal wall to the sacral promontory via an abdominal incision
- Vaginal vault suspension: Apogee system (artificial suspension of the cardinal ligaments)
- Intravaginal sling. Polypropylene sling (synthetic material) or synthetic slings (cesareal supply)
- Sacropinous fixation: Elevation and fixation of vaginal apex to sacrospinous ligaments
- Robotic or vaginal hysterectomy: Vaginal incision and fixation to surrounding structures

REFERENCE

REFERENCE
VASCULITIS, UROLOGIC CONSIDERATIONS

Description: Vasculitis is a common reaction to injury or caused by a multitude of different processes, including autoimmunity, infection, and hypersensitivity. Vasculitis can be divided into types depending on the vessel affected: Henoch-Schönlein purpura, PAN, hypersensitivity angiitis, Wegener granulomatosis, and lymphomatoid granulomatis.

A very strong correlation exists between the presence of anti-neutrophil cytoplasmic antibodies (ANCA) and the various types of systemic vasculitis, including autoimmunity, infection, and hypersensitivity. Depending on the type of vasculitis, patients present with different signs and symptoms. For example, some types can progress to chronic renal failure. However, upon renal biopsy, similar pathologic presentations are demonstrated. Can also result in renal hemorrhage. (See also Section II: “Henoch-Schönlein Purpura”)

Treatment:

- Abnormalities have proved to be extremely useful in the management of these patients. They are a help in diagnosis, and even more important as a guide to maintenance immunosuppressive therapy.
- Cysticercosis agents and cysticercoid are effective, depending on the type of vasculitis.

VASECTOMY REVERSAL, GENERAL CONSIDERATIONS (VASOVASOSTOMY)

Description: Usually accomplished with a 2-layer microsurgical vasovasostomy (9:10-0 nylon mucosal sutures, 9:0-0 nylon muscular sutures). Although surgical reversal of vasovasostomy can be technically performed on most patients, operative decision-making requires preoperative urologic and fertility evaluation of the female partner should be performed. Epididymal or testicular sperm aspiration combined with IVF/ICSI should be discussed. Results with microsurgical repair reach 85–90% success (appearing in semen), with postprocedural conception rates at 50–70%.

Treatment:

- Vasovasostomy (when sperm component of sperm are present, grade 1–4 vas fluid)
- Vasopexy/vasovasostomy (when no sperm are present in vas fluid)
- Postoperative scrotal support with abstention for 2 w

VASEOGRAPHY, TECHNIQUE AND INDICATIONS

Description: Vasography is the radiologic procedure used to evaluate patency of the vas deferens and ejaculatory ducts. The procedure involves injection of the contrast material into the vas deferens. Currently, seminal vesicle aspiration and vasography are originally replaced with microsurgery for the diagnosis of ESDO. Therefore, the primary indication for vasography is the assessment of vasal obstruction within the inguinal vas deferens. Infravesical obstruction of the vas deferens should be suspected in patients with azoospermia and previous surgeries, including orchietomy, hernia repair, vesicovaginal, and even appendectomy (iatrogenic injuries to the vas deferens). 4 techniques for vasovasostomy have been described: Vascupuncture, vasectomy, retrograde catheterization via cystoscopy and transvesical puncture. Isolated vasography (by vas puncture) is rarely performed because of the risk of subsequent scarring. It is usually a part of microsurgical reconstructive procedure. For this reason, it is not indicated to perform vasography at the time of testicular biopsy with the findings of normal spermatogenesis. If open vasography is planned, the bladder should be catheterized with a Foley catheter and balloon inflated with air to outline the bladder neck area. After crosstech exploration, the vas deferens is identified and isolated at the junction of the straight and convoluted portions. Under the operating microscope, the vasal sheath is isolated vertically and visual vessels preserved. A short segment of the sheath is excised and hemostasis is obtained using a 10-0 prolene suture. After a short distance of the sheath is excised and hemostasis is obtained using a 10-0 prolene suture. After a short distance of the sheath is excised and hemostasis is obtained using a 10-0 prolene suture.
DESCRIPTION
A technique in which urodynamic studies are performed at the same time as fluoroscopy of the lower urinary tract. The cystometry and pressure-flow studies are conducted in the same manner as regular urodynamics. The only difference is the addition of contrast and fluoroscopy. Radiation exposure is usually limited to <20 s. Adding simultaneous video enhances the evaluation of all patients, especially for more complex urodynamics problems. Videourodynamics is helpful when results from simple urodynamics do not agree with the clinical scenario. In complex bladder outlet obstruction, this technique can identify whether it occurs at the bladder neck, prostatic urethra, or distal sphincter. It is also helpful in the identification of bladder neck dysfunction in young men with voiding problems and in neuromuscular patients with dysmegacephaly of the distal sphincter. In incontinence evaluation, videourodynamics can help identify the presence and degree of vesical neck hypermobility, degree of proximal urethral weakness, and degree and type of cystocole present. In neuromuscular bladders, simultaneous video screening aids in diagnosing proximal and distal sphincter dysynergia and demonstrates the presence of reflux and bladder diverticula. The presence of reflux, bladder and urethral diverticula, fistula, and stones can be identified and characterized. (See also Section II: “Urodynamic.”)

VITILIGO, UROLOGIC CONSIDERATIONS

DESCRIPTION
A depigmentation of the skin in which sharply bordered patches become white. This is distinct from postinflammatory skin depigmentation in that there is no preceding inflammatory process. The etiology is probably autoimmune, and it is estimated to involve the outer germinative only in 10% of the adult male population. Treatment is optional and can include tetracycline, UV light, skin grafting, and cosmetic covering.

REFERENCES

TREATMENT
- Surgical correction
- Combination of pharmacologic injection therapy with a venous constriction system or a vacuum device

REFERENCE

VESICULOBULLOUS LESIONS, EXTERNAL GENITALIA

DESCRIPTION
Bullous lesions on the external genitalia mandate screening for STIs/STDs. They may be painful or painless, single or multiple, exophytic or ulcerated, confined to the genitália or occurring elsewhere on the body. Treatments vary widely based on etiology, and may require partner treatment in the case of STIs. (See also Section II: “Penis, Lesion, General”; “Sexually Transmitted Disease.”)

REFERENCE

VILEUS ADENOMA, BLADDER/URETHRA

DESCRIPTION
Villus adenomas of the bladder and urethra are rare and historically identical to those found in the colon. These tumors are more frequently found in the urethra at the dome of the bladder. On cystoscopy, these villous adenomas appear as exophytic papillary masses. Histologically, villous adenomas are composed of papillary structures lined by a pseudostratified epithelium containing goblet cells. Often, this tumor is associated with cystitis glandularis. Villous adenoma of the urethra has been reported in both males and females. In males, villous adenoma may be associated with urethral stricture, hematamia, and difficulty in micturition. In females, it may be less symptomatic and present with a slowly growing mass in the urethra. When villous adenomas are found, a primary intestinal tumor must be ruled out. After resection of the adenoma, the patient must be followed for recurrence or malignancy because their behavior is unpredictable. Diagnosis is made with urine cytology, cystoscopy, cystoscopy, or biopsy. Treatment is transurethral resection with selective cryotherapy.

REFERENCE

VIMENTIN, STAINING

DESCRIPTION
Monoclonal antibodies can be used to identify cell products or surface markers by directing antibodies against intermediate filaments. This facilitates the classification of otherwise poorly differentiated tumors. Vimentin is the predominant intermediate filament in mesenchymal cells, and it is found in all fibroblasts. Vimentin is less specific than the other intermediate filaments in immunocytochemistry because certain epithelial tumors (eg, RCC) may coexpress keratin and vimentin. (See also Section II: “Immunohistochemical Staining, Urologic Considerations.”)

REFERENCE

VINCENT CURTSY

DESCRIPTION
Holding maneuver used by children to postpone voiding or suppress urinary urgency. Vincent curtsy is performed by squating with a hand or heel pressed firmly into the perineum. Other common holding maneuvers including standing on tip-toe or forcible crossing of the legs (Image 6).

REFERENCE

ABRAMS P, CARDozo L, FALL M, ET AL. THE ICS IN 2002 PUBLISHED UPDATED GUIDELINES TO DEFINE AND CATEGORIZE LUTS INTO PATIENT-OVER A REPRESENTATIVE 24-HR PERIOD, TYPICALLY DOCUMENTS THE FOLLOWING:

- Time of urge to void
- Strength of urge or pain
- Time of actual void
- Voided volume
- Incontinence stress, urge, or unanne
- Amount of leakage small, medium, large

(VS. SECTION III: “VOIDING DIARY.”)

REFERENCE

VOIDING SYMPTOMS, DEFINITIONS (ICS DEFINITIONS)
DESCRIPTION
The ICS in 2002 published updated guidelines to define and categorize LUTS into 3 main groups including storage, voiding, and postmiction, as defined and subclassified here:

- Storage symptoms are experienced during storage phase of bladder:
  - Increased day-time frequency
  - Nocturia: Complaint that individual wakes up 1–2 times per night
  - Urgency: Complaint of sudden compelling desire to void
  - Training: Complaint of inability to control urine

- Voiding symptoms are experienced during voiding phase:
  - Slow stream
  - Splattering or spraying of urine stream
  - Intermittency during micturition
  - Hesitancy: Term used when individual has difficulty initiating micturition, resulting in a delay in the onset of voiding

- Postmiction symptoms are experienced immediately after miction:
  - Feeling of incomplete emptying
  - Postmiction dribble describes the involuntary loss of urine after the patient finishes passing urine.

REFERENCE

VOIDING DIARY FREQUENCY VOLUME CHART (FVC)
DESCRIPTION
A tool often used in association with pad testing to document the nature and severity of incontinence. A data sheet, maintained by the patient over a representative 24-hr period, typically documents the following:

- Voided volume
- Incontinence stress, urge, or unanne
- Amount of leakage small, medium, large

VOIDING SYMPTOMS, DEFINITIONS (ICS DEFINITIONS)

REFERENCE

VULVAR MALIGNANCY, UROLOGIC CONSIDERATIONS
DESCRIPTION
Vulvar carcinoma encompasses any malignancy that arises in the skin, glands, or underlying strata of the perineum, including the mons pubis, labia minora, labia majora, Bartholin glands, or clitoris. Early detection lesions (<2 cm) are critical for local control without nodal dissection. Patients presenting late in the course of disease may require radical en bloc resection of the tumor and surrounding organs. Known as pelvic exenteration. Total exenteration refers to removal of the uterus, tubes, ovaries, peritoneum, bladder, rectum or rectal segment, vagina, urethra, and a portion of the levator muscles. In an anterior exenteration, the rectum is spared, whereas in a posterior exenteration, the bladder and urethra are preserved. Urinary diversion (usually a continent catheterizable pouch) will be provided by the urologist as a portion of the pelvic reconstruction.

REFERENCE

WAGR SYNDROME (WILMS TUMOR-ANIRidia-GENital ANOMALY RETARDATION)
DESCRIPTION
WAGR syndrome is one of the Wilms tumor-associated syndromes, presenting in children <5 yr. It causes mental retardation and GU manifestations in the form of renal hypoplasia, ectopia, sacs, duplications, cystic disease, hypoplasia, cryptorchidism, and pelvic malformation. Physical exam may also reveal ear deformities, unicorneal palpebral, and anidria.

REFERENCE

WALLACE URETERAL ANASTOMOSIS
DESCRIPTION
A surgical procedure used in urinary diversion in which the ipsilateral ureter is laid adjacent and the apex of each is sutured to the other. The medial and lateral walls of the ureters are then sutured together in either an interrupted or running fashion. The Y configured ureters are then anastomosed to the end of the bowel segment used for the reservoir.

REFERENCE

WALTER REED STAGING SYSTEM, TESTIS CANCER
DESCRIPTION
Lymphangiographic criteria are used to evaluate the present and location of testicular neoplasm metastases. The following lymphangiographic patterns were found to be useful in assessing metastatic disease: filling defects, lymph node enlargement and masses, lymphatic obstruction and collateral vessel formation, and an increase or decrease in the number of lymph nodes.

**REFERENCE**

**WHITEHURST**

**DESCRIPTION**
An antegrade pressure–flow study to assess for renal obstruction. It is used to determine if polycystic or hydronephrotic urothelial Caix scroptography represents functional obstruction or anatomic dilation. This is a technically difficult, invasive test, requiring placement of a percutaneous antegrade catheter into the renal pelvis, with simultaneous monitoring of bladder and renal pelvic pressures during set flow rate of 10 mL/min. Evaluation of renal pelvic pressure over bladder pressure indicates some degree of renal obstruction. A Foley catheter must be in the bladder.

**SYNONYMS**

- Urologic antegrade pyelogram
- Intravenous pyelography
- Voiding cystourethrogram

**REFERENCE**

**WHITLOCKITE**

**DESCRIPTION**

**Miscellaneous tumors**

- Carcinoma of Skene, Cowper and Little glands
- Metastatic tumors from other organs

**OTHER UROTHELIAL NEOPLASMS**

- Adenocarcinoma
- Sarcoma

**REFERENCES**

**DESCRIPTION**
At a consensus conference of the World Health Organization (WHO) and the International Society of Urologic Pathologists (ISUP) in 1998, the WHO/ISUP classification of urothelial neoplasms of the bladder was developed. The innovations of this consensus included the elimination of grades of dysplasia, with high-grade dysplasia equated with carcinoma in situ, as well as a condensation of cytologic grading of urothelial carcinoma (ie, grades 1–3) to low- and high-grade carcinoma. In addition, a new entity was recommended for low-grade papillary lesions, entitled papillary urothelial neoplasms of low-malignant

**REFERENCE**

**WHO 2004 Histologic Classification of Tumors of the Urinary Tract**

**Urothelial Tumors**

- Infiltrating urothelial carcinoma
- with squamous differentiation
- with glandular differentiation
- with trophoblastic differentiation

WILMS TUMOR STAGING SYSTEM, INTERNATIONAL SOCIETY OF PEDIATRIC ONCOLOGY (SIOP)

WINTER CORPORAL SHUNT

DESCRIPTION: A shunt between the corpora and glans penis created to treat priapism. A Tru-Cut biopsy needle is inserted through the tip of the glans and into the corpora, and a core of tissue is removed. Through the same glans puncture site, the Tru-Cut can be reinserted in order to create 2 fistulas at the end of both corpora. It is also referred to as a percutaneous glanducavernous shunt.

WOLFFIAN DUCT REMNANTS

DESCRIPTION: Normally, an embryo develops 2 sets of paired (mullerian and wolfian) mesonephric ducts. In females, obliteration of the mullerian system fails to occur, and wolfian vestiges may persist as the epididymis, ductus deferens, ejaculatory duct, and seminal vesicles. The normal end of the wolfian duct occasionally persists as a vesical remnant, the appendix epididymis. Remnants of the mesonephric tubules may persist as a spinal structure, the paradidymis. See also Section I: “Torsions, Testicular Appendages.”

WOUND DEHISCENCE, UROLOGIC CONSIDERATIONS
DESCRIPTION
Development of a postoperative gap or deficit in the peritoneal suture line, with or without extravasation. Prevalence is in 1–3% of patients and carries a risk of mortality as high as 44%. Risk factors include anemia, hypobulinemia, advanced age, male gender, chronic lung disease, malnutrition, wound infection, and emergent procedure. Surgical variables include suture type, use of prosthetic material, incision location, hypothermia, perfusion, and oxygenation. Primary repair of initial dehiscence carries a 96% success rate with sutures and/or re-tensions, whereas the use of an interposition mesh confers an initial 100% success rate.

REFERENCE

WOUND INFECTION, POSTOPERATIVE, UROLOGIC CONSIDERATIONS
DESCRIPTION
Surgical site infections and postoperative UTIs are common causes of patient morbidity, complicating 5% and 20% of clean cases, respectively. Patient-related risk factors include advanced age, anatomic urinary anomalies, poor nutrition, tobacco use, corticosteroid use, immunodeficiency, diabetes, insulin-dependent pregnancy, diabetes, candidiasis, vaginal infection, prolonged hospitalization. The need for perioperative antimicrobial prophylaxis has been well documented. Antibiotics should be given within 60 min of procedure start time, and selected based on patient history, as well as an anticipated procedure. (See Section II: “Propylptic Antibiotics, AUA Guidelines.”) Treatment for wound infection is summarized below.

REFERENCE

KANTHOGRAMMATOSIS (ERDHEIM-CHESTER DISEASE)
DESCRIPTION
Erdheim-Chester disease is a rare non-Langerhans form of histiocytosis with a poor prognosis. This disease occurs most commonly in patients older than 50 presenting with xanthoma-like skin nodules and bilateral lower limb bone pain. Most disseminated forms of the disease can have renal failure caused by retromental and perirenal infiltrative or constrictive changes. These patients can also have cardiopulmonary insufficiency and CNS involvement and may have a progressive and fatal disease. The pathophysiology is limited with established treatments.

REFERENCE

DESCRIPTION
Collection of foamy histocytes found in the lamina propria in patients with disorders of lipid metabolism.

REFERENCE

X-LINKED SPINAL AND BULBAR ATROPHY SYNDROME (KENNEDY SYNDROME)
DESCRIPTION
Kennedy syndrome is a late-onset, bulbopspinal type of muscular atrophy. There is an X-linked recessive inheritance genetic marker CAAG repeat sequences in the androgen receptor gene (Xq28). The majority of evidence of androgen sensitivity is inherited to exaggerated or persistent adolescent gynecomastia, and the mildly high LH, testosterone, and estradiol levels characteristic of other forms of androgen insensitivity. The condition becomes prominent in the 4th–5th decades, with proximal muscle weakness and wasting; bulbar signs; fasciculations in skeletal muscles; subtle signs of endocrine dysfunction, such as diabetes, gynecomastia, or testicular atrophy, and oligospermia. The progression is very slow, and these patients can expect a normal lifespan; it is essential to distinguish this syndrome from other, often more severe neurologic diseases.

REFERENCE

XXY SYNDROME
SYNONYMS
- Klinefelter’s

XX YONOMYS
REFERENCE

XX MALE REVERSAL SYNDROME (XX MALE)
DESCRIPTION
A rare disorder of phenotypic males who have a 46, XX karyotype. Physical exam may reveal short stature; small, firm testes, a small to normal-sized penis; hypogonadism, and gynecomastia. Azospermia is typical. Seminiferous tubule sclerosis can be shown on testicular biopsy. Lab investigation reveals high gonadotropin levels and decreased testosterone levels. In most cases, other fragments from the short arm of the Y chromosome can be detected in the distal and the short arm of the X chromosome.

REFERENCE

XX SYNDROME (TRIPLE X SYNDROME, TRIPLO-X)
DESCRIPTION
Triplet X chromosome abnormalities occur in 1–2:10,000 newborn females. There are no specific diagnostic features. Mental irregularities and mental retardation have been reported. Fertility is usually preserved, and many XXX females have normal offspring.

REFERENCE

XX SYNDROME
DESCRIPTION
Rare variant of Klenefer syndrome (47, XXXY) with an additional X chromosome (48, XXXY). Phenotype is similar to 47, 48, XXXY
XXY SYNDROME (KLINEFELTER SYNDROME)

XXY with more pronounced features; these patients frequently exhibit microphalia, hypogonadotropic hypogonadism, and gynecomastia. They are infertile (azoospermia), usually are mentally retarded, and have characteristic facies.

**TREATMENT**

Supplemental testosterone may be beneficial for growth retardation and have characteristic facies.

**REFERENCE**

**XXY SYNDROME (KLINEFELTER SYNDROME)***

**DESCRIPTION**

A syndrome characterized by the presence of an extra X chromosome (usually 47, XXY), resulting in a hypogonadal male. It is the most common chromosomal aberration among men, with an estimated frequency of 1:1,500 among newborns. Caused by a nondisjunction of the sex chromosomes of the gametes from either parent, affected individuals are tall, with a eunuchoid habitus, small firm testes, and gynecomastia. Mental retardation and psychiatric disturbances have also been identified. Elevated gonadotropins and azoospermia are typically present. Seminiferous tubule sclerosis is a common finding on testicular biopsy. The diagnosis may be made by a chromatin-positive buccal smear, indicating the presence of an extra X chromosome. Karyotypes usually demonstrate 47, XXY or the milder mosaic pattern, 46, XY, 47, XXY.

**TREATMENT**

- No therapy improves spermatogenesis in Klinefelter syndrome.
- In mosaic Klinefelter syndrome with severe oligospermia, intracytoplasmic injection with IVF is technically possible.

**REFERENCES**

**FOLK SAC TUMOR, BLADDER**

**DESCRIPTION**

Follicle cell tumor of the bladder is very rare and appears to have a predilection for the urachal remnant. It has the same pathological characteristics as its counterparts in any other part of the body, and it is managed in the same way. (See Section II: “Malignant Tumor, Prostate.”)

**REFERENCE**

**FOLK SAC TUMOR, PROSTATE**

**DESCRIPTION**

Endodermal sinus tumor located in the prostate, similar to yolk sac tumor also called endodermal sinus tumor) found in the testis. A primary site of presentation in the prostate is extremely rare, with only a few reported cases. An increased incidence of extragonadal GCT is reported with Klinefelter syndrome, with postmenarche levels are commonly elevated, and are used as a tumor marker. Human chorionic gondadropin is not elevated. Schiller–Duval bodies are evident on histology. Treatment is multimodal, using cisplatin-based combination chemotherapy and radical surgery.

**REFERENCE**

**YOUNG CLASSIFICATION OF POSTERIOR URETHRAL VALVES**

**DESCRIPTION**

Young described 3 general types of posterior urethral valves:
- Type I: The valves are continuous with the ureterovesical junction and take an anterior course, dividing into 2 forks-like processes in the region of the bulbovesical junction. Usually, anterior fusion of the valves is not complete; however, some cases exhibit complete anterior fusion and drift between the 2 vestibule posteriorly. A subdivision of type I consists of a simple, instead of double, valve. Type I valves are the most common.
- Type II: Same as type I, but the valve, rather than taking an anterior course, tends to pass from the upper aspect of the verumontanum toward the external sphincter, where it divides into 2 fork-like processes. (Note: Type II valves are now thought to be nonexistent.)
- Type III: The valves have no relation to the verumontanum; instead, they are attached to the internal sphincter and the bladder neck.

**REFERENCE**

**YOUNG-DEAS-LEADBETTER BLADDER RECONSTRUCTION**

**DESCRIPTION**

This procedure was used to achieve a functional bladder neck closure for a persistent vesicoureteral reflux. It is no longer widely used. Although EDO accounts for <1% of infertility, it is a treatable entity, using transurethral resection of ejaculatory duct.

**REFERENCE**

**ZIPPER ENTRAPMENT**

**DESCRIPTION**

Usually an emergency department presentation, this penile problem usually results from the entrapment of the foreskin between the frenulum of the glans and the corona of the glans. The condition is caused by implanted sepsis, causing epispidiastomy, and treated by azospermidastomy. Birth rates remain poor.

**REFERENCE**

**ZINNER SYNDROME**

**DESCRIPTION**

Ejaculatory duct obstruction (EDO) resulting from a unilateral seminal vesicle cystic with associated obstructive kidney agenesis, the condition is caused by a congenital multicystic/lymphatic cystic abnormality. Although EDO accounts for <1% of infertility, it is a treatable entity, using transurethral resection of ejaculatory duct.
ORTHOPEDIC BONE PLIERS (see below). An alternate method of release involves cutting the closed portion of the actuator (upper teeth) with trauma shears to release the closed portion of the zipper from around the tissue.

- To remove a zipper, local anesthetic is injected into the area. Mineral oil is used to lubricate the zipper, and then 1 attempt is made to unzip the zipper. If this attempt is unsuccessful, a sturdy wire cutter (diagonal cutter) is used to cut the median bar on the top of the zipper slider, which connects its front and back plates. Then the slider falls off in 2 pieces, and the zipper teeth come apart readily (Image 1).

REFERENCES

ZONA PELLUCIDA BINDING ASSAY

DESCRIPTION
An assay used to counsel patients about their chances of success with IVF. Being species-specific, the human sperm-zona pellucida binding requires human oocytes. Different sources of oocytes can be used, such as postmortem, IVF surplus, or surgical specimens. Oocytes are bisected, and 1/2 of the zona acts as the control. Different preservation methods are available, such as salt storage, dimethyl sulfoxide freezing, or ultra-low-temperature freezing. The assay is essentially composed of 2 steps: Initial attachment, followed by irreversible binding. After repeated rinsing, the number of tightly bound spermatozoa to ZP is counted using phase contrast microscopy. This can be expressed as the hemizona index, which is the number of the patient's bound spermatozoa divided by the bound spermatozoa from the fertile control donor, multiplied by 1,003. Using a cut off of 35%, the hemizona index has been used by some to predict IVF success rate. (See also Section II: “Sperm Penetration Assay [Hamster Test].”)

Acid Phosphatase Elevation

**ACID PHOSPHATASE ELEVATION**

Acid phosphatase is produced by the prostate, RBCs, seminal fluid, and bony turnover.

- Common causes: Prostate cancer (most common), neoplasm, multiple myeloma, Paget’s, Gaucher’s, ITP, liver disease, renal failure, hyperparathyroidism, trauma.

Rectal exam

- PSA

Abnormal rectal exam or PSA

- Irregular prostate: Skeletal survey and urology referral

Normal rectal exam and PSA

Search for other causes:
- CBC, electrolytes, alkaline phosphatase, SPEP, UPEP, ESR, LFTs, B12, and TSH, TSH.

Anemia

- Determine type of anemia (ie, hemolytic). Begin treatment.
  - High ALK: Paget’s, advanced Gaucher’s
  - Low ALK: Hypothyroidism, B12 deficiency, Celiac disease, Malnutrition

No anemia

- Liver disease, early Gaucher’s, multiple myeloma

Pituitary ACTH deficiency

Turner Aneurysm Infarction Sheehan syndrome
Adrenal Mass, Solid

**ADRENAL MASS, SOLID**

- History and physical evaluation: dexamethasone suppression test or late-night salivary cortisol test, 24 hr urinary fractionated metanephrines

**功能性的肾上腺肿瘤**

- Functional adrenal mass
  - Surgical removal in most cases
  - CT
    - Delayed washout
    - Low attenuation and rapid washout
    - Surgical removal
  - MRI
    - Low signal T2
    - Follow with serial imaging and remove if enlarging or becomes functional

**非功能性的肾上腺肿瘤**

- Nonfunctional adrenal mass
  - Size ≤ 4 cm
  - MRI
    - Low signal T2
    - Surgical removal
  - Size ≥ 4 cm
    - MRI
      - High signal T2
      - Surgical removal
Anuria or Oliguria

**ANURIA OR OLIGURIA**

- **Common causes:**
  - Obstruction, acute renal failure, shock

- Check labs: UA, BUN, creatinine

- Catheterize bladder

- Urine in bladder
  - Bladder neck obstruction
    - BPH
    - Tumor

- No urine or very little
  - Low BP
    - CHF
    - Hypovolemia

  - Normal or elevated BP
    - Renal disease
    - Medications
      - Aminoglycosides
      - Gold
      - Amphotericin B
      - Chemotherapy

828
BLADDER TRAUMA

Intraperitoneal bladder rupture

Operative management

Yes

- Inadequate catheter drainage
- Vaginal or rectal injury
- Bladder neck injury
- Candidate for ORIF
- Bony fragments in bladder
- Laparotomy for other reasons

No

Cystogram

Normal

Extraperitoneal bladder rupture

Foley catheter

Pelvic ring fracture with gross or microscopic (5+ or >30 RBC/HFPF) hematuria
Gross hematuria in presence of otherwise unexplained free intraperitoneal fluid
Penetrating injury to low abdomen or pelvis with any degree of hematuria
Posterior urethral injury

Relative indications:
- Pelvis fluid collection
- Inability to void
- Elevated serum creatinine
- Abdominal distention
- Suprapubic tenderness
- Intoxicated or unresponsive
- Poorly functioning Foley catheter
- Pelvic fracture pattern
- Large pubic symphysis diastasis
- Displaced obturator ring fracture

Intraperitoneal bladder rupture

Normal

Extraperitoneal bladder rupture
**Bladder Tumor**

**BLADDER TUMOR**

- Transurethral resection of bladder tumor (TURBT)

**Staging**: Exam under anesthesia, imaging of abdomen and pelvis with upper tract imaging, check x-ray, Comprehensive Metabolic Profile (CMP)

**Primary treatment**
- Chemotherapy
- Radical cystectomy, urinary diversion (continent or conduit), and pelvic lymph node dissection is standard
- Partial cystectomy with pelvic lymphadenectomy considered in patients with no CIS, negative random bladder biopsies, no prostate involvement, and tumor located in favorable anatomical position such as a diverticulum or dome of bladder
- Multimodality treatment with chemotherapy, radiation, aggressive TURBT is being investigated
- Neoadjuvant chemotherapy provides a survival benefit. Surgery performed soon after recovery from chemotherapy

**Nonmuscle invasive**

- **Ta**
  - Low grade
  - High grade
- **T1**
  - Low grade
  - High grade
- 6-wk course of intravesical chemotherapy or BCG for the following:
  - Multifocal tumors
  - Large tumor (>2 cm)
- Repeat TURBT within 4 wk.
- 6-wk induction course of BCG followed by maintenance therapy
- Consider initial radical cystectomy in bulky high-grade disease, presence of CIS with T1 disease, presence of lymphovascular invasion
- Follow-up with cystoscopy, cytology, and interval upper tract imaging
- If CIS not present after induction BCG, start maintenance BCG
- If CIS present after induction BCG, consider cystectomy or 2nd induction course of BCG

**Muscle invasive**

- **T4b, stage IV, M1**
- Primary treatment chemotherapy
- Radical cystectomy, urinary diversion (continent or conduit), and pelvic lymph node dissection is standard
- Partial cystectomy with pelvic lymphadenectomy considered in patients with no CIS, negative random bladder biopsies, no prostate involvement, and tumor located in favorable anatomical position such as a diverticulum or dome of bladder
- Multimodality treatment with chemotherapy, radiation, aggressive TURBT is being investigated
- Neoadjuvant chemotherapy provides a survival benefit. Surgery performed soon after recovery from chemotherapy

**Follow-up with cystoscopy, cytology, and interval upper tract imaging**

- If recurrence, give 2nd 6-wk induction of BCG or consider radical cystectomy
- If CIS present after induction BCG, consider cystectomy or 2nd induction course of BCG

**Introduction BCG**

- BCG
- If CIS not present after induction BCG, start maintenance BCG
- If CIS present after induction BCG, consider cystectomy or 2nd induction course of BCG

**Repeat TURBT within 4 wk.**
Candida urinary infection (Candiduria)

**Candiduria**

- **Candiduria in asymptomatic patient**
  - Repeat clean catch urine culture
    - **Negative:** Stop
    - **Positive:** Assess for predisposing factors
      - Diabetes
      - Renal impairment
      - Broad spectrum antibiotics
      - Indwelling catheter
      - Stone disease
      - **Risk factors present**
        - Image the GU tract, r/o obstruction
        - Stop antibiotics if possible
        - Change or remove catheter
        - Glucose control in Diabetic
    - **Risk factors present**
      - Image the GU tract, r/o obstruction
      - Stop antibiotics if possible
      - Change or remove catheter
      - Glucose control in Diabetic
      - **Follow-up culture:** usually resolves in weeks to months
Cushing Syndrome

**CUSHING SYNDROME**

Common causes: Pituitary adenoma, adrenal tumor, paraneoplastic syndrome, exogenous corticosteroids

- Long-term steroid medication
  - Oral corticosteroids
  - Inhaled corticosteroids

- No long-term steroid use
  - Overnight dexamethasone suppression test or late-night salivary cortisol X2 or 24-hr urinary free cortisol X2
    - Suppressed cortisol levels
      - Pituitary adenoma
    - Normal or high levels
      - Adrenal tumor
      - Adrenal hyperplasia
      - Oat cell lung cancer

832
Cystocele and/or Enterocele

**CYSTOCELE AND/OR ENTEROCELE**

- **Cystocele and/or enterocele management**
  - (anterior compartment/pelvic organ prolapse)
  - Based on history/physical exam

**Surgical management:**
- **Vaginal approach**
  - Pelvic floor muscle therapy
  - Pessary
  - Sacrospinous ligament fixation
  - Uterovaginal ligament fixation
  - Mesh repair
  - Kelly-Kennedy plication
  - Paravaginal repair
  - Open approach
  - Laparoscopic/robotic sacrospinous ligament fixation

**Nonsurgical management:**
- Pelvic floor muscle therapy
- Pessary

**If successful, continue management:**
- Consider surgical management via vaginal or abdominal approach

**Failure to respond:**
- If there is occult stress urinary incontinence?
  - Yes
    - Consider sling
  - No
    - Conservative management

**Abdominal approach**
- Surgical management: Abdominal approach
Delayed Puberty

**DELAYED PUBERTY**

History/Physical exam: Growth pattern (stalled vs. delayed), sexual development, nutrition and exercise habits, family history (height and pubertal history), medication, and medical history

Labs:
* Basic CBC, ESR, creatinine, BUN, liver function enzymes, TSH/free T4
* Hormones: FSH, LH, prolactin, DHEA, estradiol (girls), total testosterone (boys)

Images: Bone age of left hand and wrist

Primary hypogonadism: Elevated FSH, LH

Secondary hypogonadism: Normal or low FSH, LH

Decreased estradiol

Primary gonadal failure

Decreased testosterone

Functional hypogonadotropic hypogonadism

Constitutional delay of growth and puberty

Permanent hypogonadotropic hypogonadism

**Primary hypogonadism**

Diabetes mellitus, sickle cell anemia, CIN3 disease, chronic renal failure, celiac, other chronic disease

**Idiopathic gonadal failure**

Decreased estradiol

Chronic disease

History of chemotherapy or radiation

Albino or diminishing testicular volume

**Decreased testosterone**

Primary hypogonadism

Idiopathic gonadal failure

Decreased testosterone

Decreased estradiol

Decreased testosterone

Decreased estradiol

Decreased testosterone

Decrease estradiol

Primary gonadal failure

Decreased testosterone

Functional hypogonadotropic hypogonadism
Disorders of Sexual Development (DSD)

**DISORDERS OF SEXUAL DEVELOPMENT (DSD)**

- **Ambiguous genitalia**
  - Disorder of sexual development
  - Gonads palpable:
    - Ultrasound
    - Karyotype
  - Müllerian structures absent
  - Poly X-Y
  - Variant of seminiferous tubule
    - T/DHT normal
    - Androgen insensitivity
      - Dysgenic testis
      - Leydig cell defect
  - XY or XXY
  - T/DHT elevated
  - 17-OH progesterone not elevated:
    - Consider another form of CAH if ACTH elevated
  - 17-OH progesterone elevated
  - Mixed or partial gonadal dysgenesis
  - True hermaphrodite
  - Undervirilized male

- **Müllerian structures present**
  - Müllerian structures present
    - Müllerian structure present
    - Müllerian structures absent
    - XX Müllerian structure present
    - 21-hydroxylase deficiency
    - Undervirilized male
    - True hermaphrodite
    - Gonadal dysgenesis
    - XY
    - Masculinized female
    - XX, XY, or XXXY
    - True hermaphrodite
    - Gonadal dysgenesis
    - Undervirilized male
Dyspareunia

**DYSPAREUNIA**

Common causes: Dermatitis, skin infections, UTI, vulvodynia, vaginal atrophy, vulvovaginitis, vaginal dryness, endometriosis, adenomyosis, pelvic inflammatory disease (PID), irritable bowel syndrome, inflammatory bowel disease (IBD), vaginismus, ovarian cysts, carcinoma (vulvar, cervical, lichen sclerosus, endometrial, ovarian)

Location of symptoms

- Superficial
  - Inadequate lubrication
  - Vulvodynia
  - Vulvar atrophy
  - Vaginitis
  - Vaginosus
  - Urethritis
  - Vulvar dermatitis
  - Lichen sclerosus

- Deep
  - Vaginal dryness
  - Vaginal atrophy
  - Retracted uterus
  - Endometriosis
  - PID
  - Endometrial carcinoma
  - Carcinoma
  - Cervical carcinoma

- Midline
  - Cystitis
  - IBD

- Lateral Pain
  - Ovarian cyst
  - Ovarian carcinoma
  - IBD
  - Diverticulitis

- Diffuse
  - Functional

836
DYSURIA

Causes

Common causes: Cystitis, STIs, vaginitis, prostatitis

Infectious

Noninfectious

Others

Infection of one of the following:

• Local trauma
• Labial adhesions
• Chemical urethritis

• Urinary stones
• Urethral strictures
• Reactive arthritis
• Behçet disease
• Lichen sclerosus

Genitourinary

• Pyelonephritis
• UTI
• Urethritis
• Prostatitis

Perineum

• Vaginitis (fungal, bacterial)
• Balanitis
• Pelvic inflammatory

Systemic

Less common

• Pelvic inflammatory disease
• Acropedic vaginitis
• Vulvar disease
• Vaginal warts

Urine clean catch on every patient.

Urine analysis

Urine pregnancy test

(+) Nitrates
(+ ) Pyuria

(−) Nitrates
(− ) Pyuria

Acute bacterial cystitis

Vaginal discharge

Urethral discharge

Cervical discharge

Ejaculation, Premature

**EJACULATION, PREMATURE**

**History and physical**
**Detailed sexual history**
**History of concurrent erectile dysfunction**

**Oral medication**
- Treat ED 1st if present

**Consider PDE5 inhibitors**
- SSRIs (off-label)
  - Fluoxetine
  - Paroxetine
  - Sertraline
  - Dapoxetine (EU approved)

**Topical anesthetics**
- Apply 20–30 min prior to intercourse
- Stop-start technique, squeeze technique, “quiet vagina”

**Behavioral therapy**
- Stop-start technique
- Squeeze technique
- “Quiet vagina”

**Treat ED 1st if present**

**Daily dosage or episodic dosage 3–4 hr prior to intercourse can be used**

**Dosage can be titrated up weekly until benefit**

**Enuresis**

**Wetting while asleep in a child 5 yr and older**

**ENURESIS**

- **UA/UC Positive?**
  - Yes
    - **Monosymptomatic (MSE) (Enuresis + normal UA)**
    - **Focused H&P, fluid intake, stool, and voiding diary**
    - **Daytime bladder sx**
    - **Constipation (consider functional enuresis)**
    - **No abnormality on H&P, or diary.**
    - **Persistent enuresis**
      - **Parent/child education. Behavioral therapy**
      - Resolves
      - **Enuresis alarm**
    - **Return to MSE path**
    - **Continue therapy × 6 mo**
    - **Resolves**
    - **Subspecialist referral**
    - **Evaluate for obstructive sleep apnea (OSA)**
    - **Subspecialist referral**
    - **Psychological sx (anxiety, major depressive disorder (MDD), child abuse, Attention Deficit Hyperactivity Disorder (ADHD), conduct disorder)**
    - **Immediate subspecialist referral**
    - **Subspecialist referral**
    - **Stop alarm after 14 consecutive dry nights**
    - **Family to decide if daily vs. occasional tx**
    - **Enuresis due to infection**
    - **Nonmonosymptomatic (NMSE) (enuresis + other lower urinary tract symptoms)**
    - **Focused H&P, fluid intake, stool, and voiding diary**
    - **Urinalysis & culture (UA/UC)**
    - **No abnormality on H&P, or diary.**
    - **Persistent enuresis**
      - **Parent/child education. Behavioral therapy**
      - Resolves
      - **Enuresis alarm**
    - **No**
      - **Subspecialist referral**
      - **Evaluate for obstructive sleep apnea (OSA)**
      - **Subspecialist referral**
      - **Continued medical management**
      - **Subspecialist referral**
      - **Treat underlying condition (diabetes mellitus, diabetes insipidus, chronic renal failure, seizure disorder, sickle cell, constipation, pinworm)**
      - **Immediate subspecialist referral**
      - **Subspecialist referral**
      - **Enuresis alarm**
      - **No**

**References**

Erectile Dysfunction

**ERECTILE DYSFUNCTION**

- History and focused physical exam
  - Identify common conditions that may predispose to ED
    - Hypertension
    - Diabetes
    - Cardiovascular disease
    - Hyperlipidemia
    - Depression
    - Alcoholism
    - Smoking
  - Labs: Fasting glucose, lipids, hormone panel

- If possible psychogenic cause, may consider nocturnal penile tumescence monitoring
- History of perineal trauma
- Consider vascular evaluation:
  - Combine intracavernous injection and stimulation
  - Arteriography
- Treat hormonal
- Oral phosphodiesterase type 5 (PDE5) inhibitors
- If failure and/or patient intolerance, penile prosthesis may be considered

Success:
- Periodic follow-up for efficacy, side effects, and any change in health status

Failure:
- Ensure adequate medication was performed
  - Titrate dosage
  - Switch PDE5 inhibitor
- Alprostadil intraurethral suppositories
- Intracavernous drug injection
- Vacuum constriction devices

Fecal incontinence management

Multicomponent treatment:
- Increase dietary fluid and fiber
- Improve bowel habits
- Pelvic floor muscle exercises
- Urge reduction strategies
- Barrier cream

Diarhea/loose stool consistency

- Fiber
- Loperamide
- Cholestyramine

Constipation/normal stool consistency

- Fiber
- Secondary treatment of constipation:
  - Glycerin suppositories
  - Remove causes of overflow fecal incontinence
  - Daily enemas

Biofeedback sessions

- Neuromodulation
- Artificial Sphincter
- Colostomy
Foley Catheter Problem (Difficult Placement, Male)

**FOLEY CATHETER PROBLEM (DIFFICULT PLACEMENT, MALE)**

- **History and physical:** Assess need for cathetered with admitting service. Digital rectal exam. Assess history of LUTS/BPH/urologic surgery. Give dose of antibiotic if possible infection.
- **Intraurethral lidocaine jelly:** Attempt placement of 20–22 Fr Foley or Coude catheter. Try different catheters if unsuccessful.
- **Flexible cystoscopy:** History of urologic surgery or structure disease. History of urologic trauma.
- **History of urologic surgery or structure disease:** Consider attempting 10–12 Fr catheter or initial flexible cystoscopy.
- **Retrograde urethrogram:** Suprapubic tube may be needed.
- **Flexible cystoscopy:** Able to place wire under cystoscopy. Unable to pass wire under cystoscopy.
- **Serial dilation over wire with placement of council catheter over guide wire:** Serial for possible urethrotomy or urethroplasty.
- **No stricture:** Place council catheter over guide wire.
- **Structure:** Able to place wire under cystoscopy. Unable to pass wire under cystoscopy. Serial dilation over wire with placement of council catheter over guide wire. Serial for possible urethrotomy or urethroplasty.
Genital Ulcers

Common causes: Herpes simplex, syphilis, chancroid, granuloma, inguinale

Check labs: RPR, HIV, GC, and chlamydia culture or DNA probe

Lesions painful?

Yes

No

Vesicles on erythematous base

Evolves from pinpoint ulcer to a large sore, yellowish base; associated with recurrent oral ulcers

Gram stain shows gram-negative rods, “school of fish” appearance; culture difficult

Unroof new vesicle to culture fluid

RPR +, may confirm with FTA-ABS

Punch biopsy at ulcer edge

Herpes simplex

Chancroid

Behçet disease

Syphilis

Granuloma inguinale

Genital Ulcers

843
Groin and Hip Pain

GROIN AND HIP PAIN

Common causes: OA, osteonecrosis, sciatica, stress fracture

Yes

Traumatic

No

Fracture dislocation labral tear/loose body

Yes

History of childhood pathology (such as developmental dysplasia, slipped capital femoral epiphysis, Legg–Calvé–Perthes)

No

Groin pain can be elicited by ranging hip in flexion, internal rotation or flexion, external rotation, or a resisted straight leg raise

Yes

Intra-articular

No

Extra-articular

Numbness, paresthesias or shooting pain

Location

Other

Inability to reproduce pain at site with physical exam, but exam at another site reproduces pain

Yes

Anterior iliospina tendinitis

No

Abdominal pathology must be ruled out (such as PID, nephrolithiasis, appendicitis, ovarian cysts, aneurysms, etc.)

Exercise induced?

Yes

Stress fracture

Anti-occlusive disease

844
GYNECOMASTIA

Common causes: Testicular dysfunction, drug use, congenital disorders, hypopituitarism, liver, renal, thyroid disease, obesity, carcinoma.

- Review medications
- Drug effect
- ACE inhibitor
- Marijuana
- Spironolactone
- Cimetidine
- Antiandrogens
- Alcohol
- Others
- No obvious drug
- Adolescent
- Obesity

If no other complaints and normal exam, normal findings may last 1–2 yr

- Check labs: TSH, LFTs, testosterone, serous hCG, beta hCG
- Normal findings
- Low TSH
- Hyperthyroidism
- Abnormal LFTs
- Chronic liver disease
- Testicular exam
- Abnormal
- Normal

Evidence of feminization
- Evidence of feminization
- Liver disease
- Adrenal tumor
- beta hCG-producing tumor
- Hyperprolactinemia
- Klinefelter syndrome

- Beta hCG
- Elevated
- Scrotal US
- Normal
- Testosterone

- Normal
- Scrotal US
- Mass
- Testicular germ cell tumor
- CT abdomen
- Increased LH
- Increased hCG
- Decreased LH

- Decreased LH
- Normal
- Testosterone
- Increased
- Normal
- Inhibin and/or estradiol
- Decreased LH

HEMATURIA, ADULT

Microscopic hematuria (MH): ≥3 RBCs per HPF in 2 specimens

- History and physical to assess possible causes of MH (UTI, trauma, recent urologic procedure, menstruation, etc.)
- Repeat UA/micro after treatment of other cause(s)
- Release from care

If CT urogram contraindicated, less optimal imaging:
- MR urogram
- Retrograde pyelograms in combination with non-contrast CT, MRI, or US

Renal function testing (BUN, creatinine, eGFR)
Upper tract imaging – CT urogram
Concurrent nephrology workup if indicated (proteinuria, dysmorphic RBCs, impaired renal function, etc.)

High-risk patient:
- Age >35 yr
- Smoking history
- Irritative voiding symptoms
- Chemical exposure
- Gross hematuria
- History of urologic disease

Low-risk patient

- Urinary cytology and diagnostic cystoscopy

Treat condition accordingly
Follow-up with UA/micro yearly × 2 yr
Release from care
Follow persistent MH with annual UA. Consider nephrology evaluation. Repeat anatomic evaluation every 3–5 yr or sooner if symptoms/risk factors change

Follow-up as indicated by diagnosis:
Re-evaluate for MH after resolution of condition
Release from care

HEMATORURIA, MACROSCOPIC (GROSS) PEDIATRIC

- Symptoms of glomerulonephritis, i.e., edema, HTN, proteinuria, RBC casts
  - Yes
  - No

- History of trauma
  - Yes
  - No

- Urine culture & renal US
  - Yes
  - No

- Renal ultrasound & 24-hr urine collection for metabolic stone profile
  - Yes
  - No

- Signs/symptoms of UTI
  - Yes
  - No

- Family history of kidney stone
  - Yes
  - No

- Renal US, urine culture, test parents for hematuria, hemoglobin electrophoresis, urine calcium/creatinine ratio
  - Yes
  - No

- Tumor or structural abnormality
  - Yes
  - No

- Cystoscopy with/without retrograde ureteropyelograms
  - Yes
  - No

- Treat accordingly

- Check basic metabolic panel, complete blood count, complement C3, albumin, antistreptolysin titer & streptozyme
  - Yes
  - No

- Tests consistent with post-infectious glomerulonephritis
  - Yes
  - No

- Supportive therapy
  - Yes
  - No

- Hypertension, hyperkalemia, and/or azotemia present
  - Yes
  - No

- Refer to pediatric nephrologist

- Yes
  - No
HEMURIA, PEDIATRIC MICROSCOPIC ISOLATED ASYMPTOMATIC

Repeat urinalysis weekly × 2 (without exercise)

Persistent hematuria

Test parents and siblings for hematuria

Follow-up urinalysis with physical exam

No

Positive

Family history of kidney stone

Benign familial hematuria

Consider hearing test, renal ultrasound, and hemoglobin electrophoresis depending on level of concern

Check urine calcium/creatinine ratio

Normal

If no other concerning signs/symptoms then follow with yearly urinalysis
HEMATURIA, TRAUMATIC

Hemodynamically stable
- Blunt trauma
- Microscopic hematuria
  - No hypotension
  - Adult or <50 RBCs/HPF in child
    - Repeat UA in 2–3 wk.
  - Hypotension
    - >50 RBCs/HPF in child
      - CT scan with IV and PO contrast with delayed images and CT cystogram

Hemodynamically unstable
- To OR for exploratory laparotomy with on-table IVP (2.2 mL/kg bolus IV contrast)
- IVP abnormal
  - Expanding and/or pulsatile retroperitoneal hematoma
  - Extraperitoneal bladder injury
- Repair injuries

Treat injuries or repeat UA in 2–3 wk if no injuries

Hyperaldosteronism, Primary (Aldosteronism, Conn Syndrome)

**HYPERALDOSTERONISM, PRIMARY (ALDOSTERONISM, CONN SYNDROME)**

- **Common causes:** Adrenal adenoma, adrenal hyperplasia, Cushing syndrome, renal artery stenosis, cirrhosis, nephrotic syndrome

  - **Check labs:** Plasma renin, morning plasma aldosterone, urinalysis

  - **Check medications:** Diuretics, hydralazine, laxatives

  - **Low plasma renin activity (PRA), high plasma aldosterone/PRA ratio**

  - **Confirmatory tests:** Fludrocortisone suppression, oral sodium loading test, IV saline infusion test, captopril suppression test. If negative, primary hyperaldosteronism unlikely

  - **Primary hyperaldosteronism**

  - **Adrenal adenoma, Bilateral adrenal hyperplasia**

  - **Excision or embolization**

  - **Secondary hyperaldosteronism**

  - **Renal artery stenosis**

  - **Renal disease**

  - **CHF**

  - **Cirrhosis**

  - **Dehydration**

  - **Polycystic kidneys**

  - **Glomerulonephritis**

  - **Bartter syndrome**

Hypercalcemia

Common causes:
- Hyperparathyroidism
- Malignancy
- Hyperthyroidism
- Vitamin D toxicity
- Milk-alkali syndrome
- Medications

Medications

Thiazides
Antacids
Calcium supplements
Vitamin D supplements
Lithium

Milk-alkali syndrome

PTH elevated
Phosphorus low/normal

Hyperparathyroidism
Parathyroid adenoma
Ectopic PTH secretion
Lithium

Suppressed
TSH

Barrett's disease

Paraneoplastic syndrome

Metastatic

Lung cancer
Breast cancer
Multiple myeloma
Lymphoma
Leukemia

Ovarian
Renal
Head and neck

PTH suppressed

Malignancy
- Metastatic or paraneoplastic syndrome
- Paget disease

Paget disease

Suppressed
TSH

Sarcoidosis

Check labs: PTH, phosphorus, CBC, serum protein electrophoresis (SPEP), TSH

Hyperkalemia

K+ >5.5 mEq/L

Common causes: Specimen delay and hemolysis, renal insufficiency, acidosis, rhabdomyolysis, insulin deficiency, adrenal insufficiency, medications, massive blood transfusions, tumor lysis, ischemic bowel

Clinical manifestations
- Weakness, nausea, paresthesias, palpitations, ileus, flaccid paralysis
- EKG changes: Peaked T waves, ↑ PR interval, ↑ QRS width, sine wave pattern, PEA

Repeat test

Normal
- Pseudohyperkalemia: (VF with K+ hemolyzed sample
- Check medications
- No suspicious medications
- ABGs, GFR, Cr, BUN, glucose, electrolytes, digoxin levels, CPK, urine K+

Abnormal
- Angiotensin-converting-enzyme inhibitor (ACEI), Angiotensin II receptor blockers (ARBs), β-blockers, NSAIDS, penicillin VK, TMP-SMX, digitals, K+-sparing diuretics, heparin, cyclosporine, tacrolimus, pentamidine, succinylcholine
- Discontinue medication or adjust dose

Urine K+ >30 mEq/L
- Transcellular shift

Urine K+ <30 mEq/L
- Impaired renal excretion

Acidosis
- Rhabdomyolysis
- Hyperglycemia
- Burns

Renal insufficiency
- Adrenal insufficiency
- Hyporeninemic Hypoaldosteronism

Urine K+ <30 mEq/L: Impaired renal excretion

No suspicious medications

Abnormal

Common causes: Specimen delay and hemolysis, renal insufficiency, acidosis, rhabdomyolysis, insulin deficiency, adrenal insufficiency, medications, massive blood transfusions, tumor lysis, ischemic bowel

Clinical manifestations
- Weakness, nausea, paresthesias, palpitations, ileus, flaccid paralysis
- EKG changes: Peaked T waves, ↑ PR interval, ↑ QRS width, sine wave pattern, PEA

Repeat test

Normal
- Pseudohyperkalemia: (VF with K+ hemolyzed sample
- Check medications
- No suspicious medications
- ABGs, GFR, Cr, BUN, glucose, electrolytes, digoxin levels, CPK, urine K+

Abnormal
- Angiotensin-converting-enzyme inhibitor (ACEI), Angiotensin II receptor blockers (ARBs), β-blockers, NSAIDS, penicillin VK, TMP-SMX, digitals, K+-sparing diuretics, heparin, cyclosporine, tacrolimus, pentamidine, succinylcholine
- Discontinue medication or adjust dose

Urine K+ >30 mEq/L
- Transcellular shift

Urine K+ <30 mEq/L
- Impaired renal excretion

Acidosis
- Rhabdomyolysis
- Hyperglycemia
- Burns

Renal insufficiency
- Adrenal insufficiency
- Hyporeninemic Hypoaldosteronism

Urine K+ <30 mEq/L: Impaired renal excretion

No suspicious medications

Abnormal

Common causes: Specimen delay and hemolysis, renal insufficiency, acidosis, rhabdomyolysis, insulin deficiency, adrenal insufficiency, medications, massive blood transfusions, tumor lysis, ischemic bowel

Clinical manifestations
- Weakness, nausea, paresthesias, palpitations, ileus, flaccid paralysis
- EKG changes: Peaked T waves, ↑ PR interval, ↑ QRS width, sine wave pattern, PEA

Repeat test

Normal
- Pseudohyperkalemia: (VF with K+ hemolyzed sample
- Check medications
- No suspicious medications
- ABGs, GFR, Cr, BUN, glucose, electrolytes, digoxin levels, CPK, urine K+

Abnormal
- Angiotensin-converting-enzyme inhibitor (ACEI), Angiotensin II receptor blockers (ARBs), β-blockers, NSAIDS, penicillin VK, TMP-SMX, digitals, K+-sparing diuretics, heparin, cyclosporine, tacrolimus, pentamidine, succinylcholine
- Discontinue medication or adjust dose

Urine K+ >30 mEq/L
- Transcellular shift

Urine K+ <30 mEq/L
- Impaired renal excretion

Hypernatremia

**HYPERNATREMIA**

**History and volume status**

**Hypovolemic:**
- Dermal losses
- GI losses
- Diuretics
- Postobstruction
- Acute and chronic renal disease
- Hyperosmolar nonketotic coma

**Euvolemic:**
- Diabetes insipidus (central, nephrogenic)
- Hypodipsia
- Fever
- Hyperventilation
- Mechanical ventilation

**Hypervolemic:**
- Hypervolemic
- Hypovolemic
- Diabetes insipidus (hypertonic saline, tube feedings, antibiotic containing sodium)
- Hyperaldosteronism
- Cushing disease

Obtain urine and plasma osmolality and urinary sodium

**Urine osmolality/plasma osmolality < 0.7 mOsm/kg**

- Diabetes insipidus
- Hypodipsia
- CNS lesion

**Urine osmolality/plasma osmolality > 0.7 mOsm/kg**

- Urine sodium < 20 mEq/L

- Renal:
  - Diuretics (osmotic, loop)
  - Interstitial renal disease
  - High-protein diet

- Endocrine:
  - Cushing disease
  - Primary hyperaldosteronism
  - Diabetes mellitus

- GI losses:
  - Lactulose malabsorption
  - Infectious diarrhea

- Respiratory losses:
  - Hyperventilation

- Skin losses:
  - Excessive sweating

853
Hypertension and Elevated Blood Pressure, Treatment

HYPERTENSION AND ELEVATED BLOOD PRESSURE, TREATMENT

BP: SBP <120 and DBP <80

Measured on 2 separate office visits

Yes

No

At goal?

Yes

No

DM or CKD

Goal BP: <140/90

Lifestyle modifications:
DASH diet, weight reduction, moderate consumption of alcohol, limit NSAIDs, physical activity, smoking cessation

First-line: Thiazide type diuretics
Second-line: Consider ACE-I, BB, CCB, or combination

Compelling Comorbidities
Include: CAD, CVA, CHF (ACEi or BB for CHF)
Add other antihypertensive drugs to meet goal: Diuretics, ACE-I, BB, CCB as needed

Lifestyle modifications:
DASH diet, weight reduction, moderate consumption of alcohol, limit NSAIDs, physical activity, smoking cessation

First-line: Thiazide type diuretics AND Second-line: Consider ACE-I, BB, CCB, or combination until goal is met

Heart failure
Initial therapy options: Thiazide, BB, ACE-I, ARB, Aldosterone antagonist

Postmyocardial infarction Initial therapy options: BB, ACE-I, ARB, Aldosterone antagonist

High CAD risk
Initial therapy options: Thiazide, BB, ACE-I, CCB

Diabetes
Initial therapy options: Thiazide, ACE-I, ARB, CCB

Chronic kidney disease
Initial therapy options: ACE-I, ARB

Recurrent stroke prevention
Initial therapy options: Thiazide, ACE-I

854
Hypocalcemia

**HYPOCALCEMIA**

Common causes: Lab error, chronic renal failure, postsurgical hypoparathyroidism, hypoalbuminemia, hypomagnesemia, hyperphosphatemia, medication, PTH deficiency or resistance, vitamin D deficiency or resistance.

Check labs: Repeat serum calcium, ionized calcium, electrolytes, BUN, creatinine, magnesium, phosphorus, albumin, LFTs, PT, PTT, PTH.

**Serum calcium >8.5 mg/dL**
- Bound to albumin
- If ionized calcium not available, correct calcium for albumin; calcium concentration falls by 0.8 mg/dL for every 1 g/dL fall in albumin.

**Calcium <8.5 mg/dL, ionized or corrected calcium low, albumin normal or slightly low**
- Magnesium low
- Phosphorus low
- PTH high
- PTH low
- Hypomagnesemia
- Hypoparathyroidism
- Rickets
- Abnormalities of vitamin D metabolism
- Pseudohypoparathyroidism

**Calcium <8.5 mg/dL, ionized or corrected calcium normal, albumin low**
- Hypoalbuminemia
- Cirrhosis
- Nephrotic syndrome
- Malnutrition
- Burns
- Chronic illness
- Sepsis

Hypokalemia

**HYPOKALEMIA**

**HISTORY TAKING**

- No transcellular shift, adequate K intake, obtain serum electrolytes, BUN, Cr, Urine Na, K, and osmolality

**INADEQUATE INTAKE**
- Potassium deficient diet:
  - Tea and toast diet
- Eating disorders:
  - Anorexia, bulimia, starvation, pica
  - inability to eat potassium-poor TPN

- **AML:** Acute myelogenous leukemia,
- **OD:** Overdose
- **GI:** Gastrointestinal,
- **UK:** Urine potassium;
- **TTKG:** transtubular potassium gradient
- **UCl:** urine chloride

**SPURIOUS**
- Leukocytosis (WBC >100K)
- AML: Severe lipemia

**TRANSCELLULAR SHIFT**
- Gill-adrenergic agonists:
  - Epinephrine
- Decongestants:
  - Pseudoephedrine, phenylpropanolamine
- Bronchodilators: Abuterol, terbutaline, isoproterenol, ephedrine, malatoperoentol
- Tocolytic: ritodrine, nylidin
- Theophylline
- Chloroquine
- Caffeine
- Verapamil
- Insulin
- Alkalosis
- Increased anabolic state
- Increased in RBC production: Pericusic anemia (Wt Hb)
- Neutropenia (Gl-CSF)
- Thyrototic periodic paralysis
- Barium intoxication
- Pheochromocytoma
- Hypokalemia periodic paralysis
- Refeeding syndrome
- Hypothermia
- Delirium Tremens

**RENAL LOSS**
- Profuse sweating
- UK >30 mEq/d
- TTKG** >7
- UK <25 mEq/d
- TTKG** <3

**GI LOSS**
- Vomiting
- Diarrhea
- GI suction
- Draining GI fistula
- laxatives
- Secretory tumors:
  - Villous adenoma,
  - VIPoma,
  - Zolinger–Ellison syndrome
- Inability to eat potassium-poor TPN

**INSENSIBLE LOSS**
- Hypnormotensive
- Base status

**ACIDEMIC**
- DKA
- RTA type II
- Some distal RTA type I

**VARIABLE**
- Mg deficiency:
  - Amphotericin B
  - Cisplatinum
  - Aminoglycosides:
  - Foscarnet
  - Poor Mg intake

- <20 Vomiting
- NGT

**ALKALEMIC**
- UCI
- >20 Diuretics
- Bartter’s/Gilberman’s

**Hypertensive**
- Primary hypaldosteronism: Conn syndrome
- Secondary hyperaldosteronism:
  - renovascular disease, renin-secreting tumor
- Nonaldosterone mineralocorticoid:
  - Cushing’s, Liddle’s, exogenous mineralocorticoid, licorice

**INADEQUATE INTAKE**
- Potassium deficient diet:
  - Tea and toast diet
- Eating disorders:
  - Anorexia, bulimia, starvation, pica
  - inability to eat potassium-poor TPN

**MEDICATIONS**
- Diuretics
- Bicarbonate
- Methylenanthrene OD
- Amphotericin B
- Cisplatin
- Chloroquine intoxication
- Verapamil OD
- Beta agonist intoxication
- Ephedrine

**TTKG** = Urine K⁺ x serum osmolality/Serum K⁺ x urine osmolality
- <3 kidney is not wasting excessive potassium >7 significant renal loss

856
Hypomagnesemia

**HYPOMAGNESEMIA**

- **Common causes:**
  - GI loss
  - Malnutrition
  - Malabsorption
  - Diuretics
  - Alcoholism

- **24-hour urinary magnesium**

- **FE_{Mg} = \frac{U_{Mg} \times P_{Cr}}{(0.7 \times P_{Mg}) \times U_{Cr}} \times 100**

- **FEMg < 2% or**
  - 24 hr U_{Mg} > 30 mg

- **FEMg > 2% or**
  - 24 hr U_{Mg} < 10 mg

- **Renal**
  - Impaired renal function: GFR < 60
  - Normal renal function: GFR > 80

- **Acquired:**
  - Chronic renal failure
  - Acute tubular necrosis
  - Renal tubular acidosis
  - Postobstructive diuresis
  - 1° Aldosteronism
  - Hyperparathyroidism
  - Hyperthyroid
  - SIADH
  - Hyperaldosteronism

- **Redistribution:**
  - Hungry bone syndrome
  - Pancreatitis
  - Insulin treatment
  - Transfusion
  - Refeeding syndrome

- **Endocrine:**
  - Hyperparathyroidism
  - Hyperthyroid
  - SIADH
  - Hyperaldosteronism

- **Malabsorption:**
  - Celiac sprue
  - Crohn disease
  - Small bowel resection

- **Poor intake:**
  - Malnutrition
  - Starvation
  - Mg-free IVF
  - TPN

- **GI loss:**
  - Vomiting
  - Diarrhea
  - NG suction
  - Intestinal fistula

- **Miscellaneous:**
  - Chronic alcoholism
  - Diabetes mellitus

- **Medications:**
  - Diuretics: loop/thiazide
  - PPI
  - Aminoglycoside
  - Amphotericin B
  - Cisplatin
  - Cyclosporin
  - Cetuximab
  - Tacrolimus
  - Foscarnet
  - Pentamidine

- **Congenital:**
  - Bartter syndrome
  - Gitelman syndrome

**FEMg =** Fractional excretion of magnesium
**UMg =** urinary magnesium
**UCr =** Urinary creatinine
**PCr =** Plasma creatinine

857
Hyponatremia

**HYPONATREMIA**

Serum osmolality

- <280 mEq/L
  - Pseudohyponatremia:
    - Hyperlipidemia
    - Hyperproteinemia
    - Hyperglycemia
    - Mannitol

- ≥280 mEq/L
  - Hypovolemic:
    - Poor skin turgor, dry mucous membranes
  - Hypervolemic:
    - Edema, ascites
    - 3rd heart sound

What is the volume status?

- Hypovolemic: U Na <20 mEq/L
  - GI losses
  - Sweating
  - Burns
  - Cystic fibrosis
  - Exercise
  - Bleeding

- Hypervolemic: U Na >20 mEq/L
  - CHF
  - Nephritic syndrome
  - Liver failure
  - Pregnancy

- Euvolemic
  - U Na <20 mEq/L
  - CHF
  - Addison disease
  - SIADH
  - Cerebral salt wasting

- U Na >20 mEq/L
  - Diuretic use

U Na = Urinary sodium

Hypospadias

**HYPOSPADIAS**

- With chordee
  - Release chordee without preservation of urethral plate
  - Two-stage graft urethroplasty using buccal mucosal graft or prepuce
  - Release chordee with preservation of urethral plate
- Without chordee
  - Release chordee without preservation of urethral plate
  - Preputial island tube urethroplasty
  - Tubularized incised plate onlay island flap (with bad urethral plate)
  - Tubularized incised plate
  - Tubularized incised plate Glans approximation procedure
  - Glans approximation procedure Meatal advancement and glanduloplasty (MAGPI)
  - Proximal/midshaft
  - Distal
  - Coronal
  - Glandular
Incontinence, Female

INCONTINENCE, FEMALE

- History and physical exam
- Urine analysis and culture
- Uroflowmetry and postvoid residual
- Symptom and quality-of-life questionnaire
- Micturition diary
- Urodynamics if indicated:
  - Simpler tests inconclusive
  - Empirical treatment fails
  - Proposed surgery
  - History of pelvic surgery/radiation
  - Neurologic conditions
- Voiding cystourethrogram in select patients
- Cystourethroscopy in select patients

Incontinence associated with poor bladder emptying or retention

VCUG
Urodynamics
Identify correct pathology:
- Iatrogenic from prior surgery
- Pelvic organ prolapse
- CIC if underactive detrusor muscle

Evaluate and treat possible fistula or ectopic ureter

Continuous incontinence
Urgo incontinence
Mixed incontinence: Treat main problems first
Stress incontinence

Initial treatment options:
- Pelvic floor muscle training/behavior modification
- Biofeedback
- Oral anticholinergic agents (eg, oxybutinin, tolterodine, mirabegron, etc.)
- Intravesical agents (Botulinum toxin, etc.)
- Percutaneous tibial nerve stimulation

Surgery considered when less-invasive treatments fail or are not tolerated:
- Sacral neuromodulation
- Augmentation cystoplasty
- Urinary diversion

Initial treatment options:
- Pelvic floor muscle training/behavior modification
- α-adrenergic agents (limited utility)
- Imipramine
- Duloxetine (not FDA approved)
- Pessary

Minimally invasive options:
- Urethral bulking agents

Surgical options:
- Slings
- Suspensions
- Prosthesis repair
- Artificial urinary sphincter

Initial treatment options:
- Pelvic floor muscle training/behavior modification
- Biofeedback
- Oral anticholinergic agents (eg, oxybutinin, tolterodine, mirabegron, etc.)
- Intravesical agents (Botulinum toxin, etc.)
- Percutaneous tibial nerve stimulation

Surgery considered when less-invasive treatments fail or are not tolerated:
- Sacral neuromodulation
- Augmentation cystoplasty
- Urinary diversion

Initial treatment options:
- Pelvic floor muscle training/behavior modification
- Biofeedback
- Oral anticholinergic agents (eg, oxybutinin, tolterodine, mirabegron, etc.)
- Intravesical agents (Botulinum toxin, etc.)
- Percutaneous tibial nerve stimulation

Surgery considered when less-invasive treatments fail or are not tolerated:
- Sacral neuromodulation
- Augmentation cystoplasty
- Urinary diversion
Incontinence, Male

**INCONTINENCE, MALE**

- Urinary incontinence, male

  - Post-micturition dribble
  - Post-prostatectomy incontinence
  - Incontinence with urgency/frequency

**STRESS INCONTINENCE**

- Urethral milking
- Pelvic floor muscle training

**MIXED INCONTINENCE**

- General assessment
- Urinary diary and symptom score
- Assess quality of life and desire for treatment
- Physical examination: abdominal, rectal, sacral neurologic
- Urinalysis ± urine culture ➞ If infected, treat and reassess
- Assess PVR: physical exam./catherization/ultrasound

**URGE INCONTINENCE**

- Lifestyle interventions
  - Pelvic floor muscle training
  - Bladder retraining
- Antimuscarinics

**Specialized management**

- Failed initial therapy
  - Urethrocystoscopy
  - Urodynamics

**Post-prostatectomy**

- Incontinence on physical activity
- Incontinence with urgency/frequency

**OVERFLOW INCONTINENCE**

- Sphincteric incompetence
  - If initial therapy fails:
    - Artificial urinary sphincter
    - Sling procedures
    - Bulking agents

- Overactive detrusor
  - If initial therapy fails:
    - Neurostimulation
    - Sacral blockade
    - Botulinumtoxin detrusor injections
    - Bladder augmentation/substitution

- Underactive detrusor
  - Intermittent catheterization (IC)
  - Alpha-blockers
  - 5-α-reductase inhibitors
  - Neurostimulation
  - Correct anatomic defects

- Bladder outlet obstruction
- Consider:
  - Urethrocystoscopy
  - PVR/flow rates
  - VCUG/urethrogram
  - Ultrasound/IVP

- Lower urinary tract anomaly/pathology
  - Correct anomaly
  - Treat pathology

861
Incontinence, Pediatric

INCONTINENCE, PEDIATRIC

Pattern of wetting

Normal with nocturnal enuresis

Maturational delay

- Lumbar-sacral spine x-ray
- Renal US

<8 y/o

Normal
- VCUG
- MRI of spine
- Urodynamics

Abnormal
- Education
- Bed wetting alarm

>8 y/o

Normal with diurnal enuresis

Continuous

VCUG, Renal US

Intermittent

Dysfunctional voiding

VCUG, Renal US

- Timed voiding
- Bowel regimen
- Pharmacotherapy

Neurogenic abnormality

No UTI

UTI

Eccopic ureter

Exstrophy

Urodynamics

Medical or surgical treatment

- Timed voiding
- Bowel regimen
- Pharmacotherapy
- Need for clean intermittent catheterization (CIC)

>8 y/o

<8 y/o

Neurogenic abnormality

Ectopic ureter

Exstrophy

Surgery

Medical or surgical treatment
Infertility

Infertility

Common causes: Endocrine disorders (Polycystic ovary syndrome [PCOS], thyroid disease, hyperprolactinemia), pelvic structural abnormalities, azoospermia/oligospermia, unexplained infertility, poor coital timing/frequency

Evaluate coital timing and frequency

Female factor

Male factor

Patient history, physical, pelvic exam

Semen analysis

Uterine/tubal evaluation hysterosalpingogram

Assess ovulation using basal body temperature chart, urine LH ovulation predictor kit, and midultral serum progesterone

Positive for gonorrhea/chlamydia

Evaluate and treat for PID

Normal semen

Abnormal semen

Uterine abnormality

Tubal abnormality

Consider genetic evaluation

Consider testicular biopsy

History and physical exam

Endocrine evaluation

Normal

Abnormal

Ovulatory

Oligoovulation

If >35 y/o evaluate ovarian resistance with menses day-3 serum FSH or clomiphene citrate challenge test

Measure serum FSH, LH, TSH, and prolactin (PRL) levels

If low/normal FSH/LH or high PRL perform CT scan or MRI to evaluate for hypothalamic/pituitary disorder

Progestin challenge test

If hirsutism present determine serum 17-hydroxyprogesterone and testosterone levels to evaluate for PCOS and congenital adrenal hyperplasia (CAH)

If low/normal FSH/LH or high PRL perform CT scan or MRI to evaluate for hypothalamic/pituitary disorder

Semen analysis

Normal semen

Abnormal semen

Measure serum FSH, LH, testosterone, PRL

History and physical exam

Endocrine evaluation

If hirsutism present determine serum 17-hydroxyprogesterone and testosterone levels to evaluate for PCOS and congenital adrenal hyperplasia (CAH)

INFERTILITY, MALE ABNORMAL SEMEN

- Infertility, male – abnormal sperm parameters
  - Semen analysis × 2
    - Morning testosterone, LH, FSH, prolactin (PRL)
      - Abnormal
        - Low testosterone, Low FSH/LH
          - Secondary testicular failure
            - Karyotype
              - Y-chromosome microdeletion
                - Normal prolactin
                  - Rule out pituitary tumor
                    - Normal
                      - Other causes
                        - Medical or surgical treatment
        - High FSH, LH, Low testosterone
          - Primary testicular failure
            - Sertoli only
              - High prolactin
                - Head MRI
                  - Normal
                    - Abnormal
      - Normal
        - High LH, High testosterone
        - Androgen resistance
        - High FSH only
          - Sertoli only
            - No varicocele
              - Palpable varicocele
                - Repair
        - Check for varicocele
          - Low testosterone, Low FSH/LH
        - Secondary testicular failure
INFERTILITY, MALE, LOW SEMEN VOLUME

Semen analysis > 2 with >48 hr of abstinence

Semen volume <2 mL

Cystoscopy/Retrograde Urethrogram if:
1. Obstructive symptoms
2. History of strictures
3. Risk for stricture

Post-ejaculate urinalysis

Sperm present

Retrograde ejaculation

Sperm absent

TRUS with seminal vesicle aspiration

Dilated seminal vesicle or ejaculatory

Transurethral resection of ejaculatory duct
Lower Urinary Tract Symptoms (LUTS), Male

LOWER URINARY TRACT SYMPTOMS (LUTS), MALE

History and physical
Digital rectal exam
Urinalysis
PSA in select patients
Urine cytology in at-risk patients

Presence of the following clearly related to benign prostatic hypertrophy (BPH):
- Bladder stones
- Renal insufficiency
- Persistent gross hematuria
- Recurrent UTI

Mild symptoms (AUA/IPSS ≤ 7) or symptoms not bothersome
Watchful waiting

Moderate (AUA/IPSS 8–19) or severe (AUA/IPSS 20–35) symptoms
Watchful waiting

AUA/IPSS symptom index
Assessment of patient bother

Surgery

Mild symptoms (AUA/IPSS ≤ 7) or symptoms not bothersome
Watchful waiting

Optional tests:
- Uroflow
- PVR

Discussion of treatment options

Patient chooses noninvasive therapy
Watchful waiting

Patient chooses invasive therapy

Optional tests:
- Urodynamics
- Cystoscopy
- Prostate US

Surgery or minimally invasive therapy

Lymphadenopathy

**LYMPHADENOPATHY**

- **Localized** (1 site)
  - Low risk of malignancy: Tender, rubbery movable LNs
    - Yes
      - Apparent infectious or inflammatory disease?
        - Yes
          - Guided FNA/excisional biopsy
        - No
          - Observe for 3–4 wk
    - No
      - LN ultrasoundography: Round, absent hilus, Doppler with disorganized peripheral vascular pattern
        - Yes
          - Diagnostic?
            - Yes
              - Follow-up
              - Reactive pattern
              - Positive for malignancy
              - Inconclusive
              - CT scan directed to drainage area for diagnostic/staging purposes
              - Tissue diagnosis of primary tumor
            - No
              - Reassurance
          - No
            - Reassurance
    - Persistent?
      - Yes
        - Guided FNA/excisional biopsy
      - No
        - Reassurance

- **Generalized** (2 or more sites)
  - Risk of malignancy: Nontender, hard, fixed or matted, progressively enlarging LNs, supravacular location
    - Yes
      - Review history:
        - Search clues for infectious, inflammatory, autoimmune or neoplastic diseases. Review medications.
        - Chest x-ray, CBC, mononucleosis, and CMV serology, PPD, RPR, ANA, HBsAg, HIV, protein electrophoresis, LDH
      - CT scan directed to drainage area for diagnostic/staging purposes
        - Yes
          - Tissue diagnosis of primary tumor
        - No
          - Repeat biopsy
    - No
      - Infectious:
        - HIV
        - Syphilis
        - CMV
        - EBV
        - Hepatitis
        - Tuberculosis
      - Inflammatory:
        - Sarcoidosis
        - Autoimmune:
          - Rheumatoid Arthritis
          - Lupus
        - Neoplastic:
          - Hodgkin disease
          - Non-Hodgkin Lymphomas
          - Leukemia
          - Drugs:
            - Allopurinol
            - Atenolol
            - Captopril
            - Carbamazepine
            - Cephalosporins
            - Gold
            - Hydralazine
            - Penicillin

Follow-up

Metabolic Acidosis

**METABOLIC ACIDOSIS**

- **Anion gap (AG)**

  \[ \text{AG} = \text{Na}^+ - (\text{Cl}^- + \text{HCO}_3^-) \]

- Normal: \(<12 \text{ mEq/L} \)

- **Calculate** \( \Delta/\Delta \) (delta/delta ratio)

  \[ \frac{\text{AG} - 12}{\text{HCO}_3^- - 24} \]

- **AG**

  - \( \geq 12 \) AG
  - \(< 12 \) AG

**1–2 Metabolic acidosis**

- Check urine or serum ketones (or \( \beta \)-hydroxy butyrate if pH < 7.1 & ketone negative)

**≤1 AG metabolic acidosis & nonanion gap metabolic acidosis**

**>2 Metabolic acidosis & metabolic alkalosis or respiratory acidosis**

**Normal glucose**

**Elevated glucose**

- Elevated BUN/creatinine

  Yes: DKA

  No: Consider malnutrition, alcoholic ketoacidosis

- No: Serum lactate

  Yes: Renal failure–induced metabolic acidosis

- Decreased or normal: Check osmolar gap = measured osmolality – calculated (2[Na+] + glucose + BUN/2.8 + ethanol/4.6)

- Elevated: Lactic acidosis (hypoperfusion), shock, sepsis, liver or renal failure

- <10 mOsm: Obtain salicylate level

- ≥10 mOsm: Obtain ethylene glycol and methanol levels

868
**METABOLIC SYNDROME, TREATMENT**

1. **Identify risk factors**
   - Abdominal obesity, insulin resistance, physical inactivity, high BMI, high-carb diet, cigarette smoking, Western diet, 1–2 sugar-sweetened beverages/day, patients with known cardiovascular disease.

2. **Assess**
   - Is waist circumference >40” (102 cm) - men or >35” (88 cm) - women?
   - Serum triglycerides ≥1.7 mmol/L (150 mg/dL) or on lipid lowering therapy.
   - Serum HDL <1.03 mmol/L (40 mg/dL) in men or <1.3 mmol/L (50 mg/dL) in woman.
   - SBP ≥130 mm Hg or DBP ≥85 mm Hg or treatment of previously diagnosed HTN.
   - Fasting plasma glucose ≥5.6 mmol/L (100 mg/dL) or previously diagnosed DM2.

3. **Does patient meet 2 of 4 criteria above?**
   - Yes
   - No

4. **Treat physical inactivity**
   - Regular moderate-intensity physical activity; 30–60 min of continuous or intermittent exercise 5 d/wk. (Level 3)

5. **Treat abdominal obesity**
   - 7–10% body weight reduction in 1st year of therapy. Weight maintenance/reduction through balanced physical activity, reduced caloric intake, and lifestyle changes. (Level 3)

6. **Treat elevated BP**
   - Physical activity (see above)
   - Weight reduction
   - Pharmacotherapy if indicated for BP >140/90. (Level 3)

7. **Treat elevated glucose**
   - Physical activity (see above)
   - Weight reduction
   - Pharmacotherapy if necessary to delay progression to DM. (Level 3)

8. **Consider and treat alternative**
   - Hypertension, hyperlipidemia, diabetes, obesity

Nephrotic Syndrome

Suggesting symptoms and signs:
Edema, foamy urine, weight gain, hypoalbuminemia

Urine dipstick analysis

≥3–4 + protein

Yes

SPOT URINE COLLECTION
Random urine protein/creatinine

Yes/conformation

≥3–3.5 g/24 h

Yes

24-HOUR URINE COLLECTION
Gold standard

Obtain:
- CBC w/diff., ESR, BUN/creatinine, electrolytes, glucose, serum albumin, lipid panel, HIV, hepatitis panel, RPR, ANA, anti-dsDNA, complement (C3 and C4) levels.
- Symptoms or History of: DM, SLE, Hep B or C, NSAID use/abuse, pregnancy, multiple myeloma?

Renal biopsy

Normal-appearing glomeruli on renal biopsy microscopy; effacement of foot processes on electron microscopy

Thickening of the glomerular basement membrane on electron microscopy; IgG and C3 deposits with immunofluorescent staining

Sclerosis and hyalinosis of segments of <50% of all glomeruli on electron microscopy deposits with immunofluorescent staining

Minimal change disease

Membranous nephropathy

Focal segmental glomerulosclerosis

SECONDARY NEPHROTIC SYNDROME

Diabetic nephropathy

Systemic lupus

Hepatitis B & C

Preeclampsia

Multiple myeloma

HIV

Amyloidosis

Nocturia

**NOCTURIA**

- **Voiding diary**
  - NPI (nocturnal polyuria index) >35%
  - Diminished nocturnal bladder capacity (NBC)
  - 24-hr urine volume >40 mL/kg

**Nocturnal polyuria**
- CHF
- Diabetes mellitus
- Peripheral edema
- Excessive nighttime fluid intake
- Sleep apnea
- Medications
- Venous stasis

**Mixed (nocturnal polyuria + low nocturnal bladder capacity)**

**Low nocturnal bladder capacity**
- Detrusor overactivity (neurogenic/non neurogenic)
- Voiding dysfunction
- Inflammatory (UTI, radiation cystitis, stones)
- Neoplasia (BPH, urothelial carcinoma of the bladder or CIS)

**24-hr (global) Polyuria**
- Diabetes mellitus
- Diabetes insipidus
- Primary polydipsia

**NPI**: Night-time urine output greater than 35% of the daily total in older adults.
Parathyroid Hormone, Elevated Serum

**PARATHYROID HORMONE, ELEVATED SERUM**

Common causes:
- Parathyroid adenoma, parathyroid hyperplasia, ectopic PTH, renal failure, lithium, small bowel disease, chronic pancreatitis, low calcium intake, vitamin D deficiency, familial hypocalciuric hypercalcemia (FHH), MEN 1

Check labs:
- Total serum calcium, PO4, 25-hydroxy vitamin D, urinary Ca:Cr

Serum Ca on 2 occasions; ± clinical signs of hypercalcemia

Primary hyperparathyroidism

- Parathyroid adenoma
- Parathyroid hyperplasia
- Ectopic PTH
- Lithium
- MEN 1

Or if urinary Ca:Cr

Tertiary hyperparathyroidism: follows long-standing secondary hyperparathyroidism

Secondary hyperparathyroidism

- Renal failure
- Chronic pancreatitis
- Low calcium intake
- Vitamin D deficiency

Familial hypocalciuric hypercalcemia (FHH)

PELVIC PAIN, FEMALE

Common causes: Menstrual cramps, PID, ectopic pregnancy, fibroid uterus, endometriosis, ovarian cyst

Pregnancy test

+ Pregnancy test
  - Ectopic pregnancy
  - Normal gestation

- Pregnancy test
  - Cyclic pain
  - Acute pain
  - Gradual onset

Menstrual cramps
Endometriosis
Adenomyosis

PID
Ovarian torsion
UTI
Appendicitis
Diverticulitis

Uterine fibroids
Ovarian tumor
Functional disorder

Penis, Squamous Cell Carcinoma

**PENIS, SQUAMOUS CELL CARCINOMA**

- History and physical
- Incisional–excisional biopsy of lesion
- Exam inguinal lymph nodes (IGN) with CT scan if palpable nodes
- Penile US assess proximal extent

- Tumor on prepuce
- Circumcision with intraoperative frozen section analysis

- Distal tumor
- Partial penectomy with intraoperative frozen section analysis >2 cm

- Proximal tumor
- Total penectomy

- Tis, Ta, T1G1–2, no vascular invasion
- If IGN are palpable give 4 wk of antibiotics and reassess

- T2–T4, vascular invasion, grade 3
- Palpable IGN
- Ipsilateral superficial and deep inguinal and pelvic node dissection. Contralateral superficial inguinal dissection.

- Nonpalpable IGN
- Observe

- Consider FNA and excisional biopsy for Tis and Ta tumors prior to node dissection

- Consider adjuvant chemotherapy if T4 disease, >2 nodes positive, bilateral metastasis, extranodal extension, or positive

- Perform deep inguinal and pelvic lymph node dissection if superficial dissection positive on that side

- Bilateral superficial inguinal node dissection
PENIS, TRAUMA

History and physical
Urine analysis
Retrograde urethrogram (RUG) in most cases

Traumatic amputation
Penetrating injury
Penile fracture

Immediate exploration
Close corporal defects with 2-0 or 3-0 absorbable suture
Inspect spongiosum and urethra

Partial urethral injury
Over-sew with fine absorbable sutures over catheter

Complete urethral injury
Debride, mobilize, and primary anastomosis over urethral catheter

Microvascular reimplantation if severed part available, close corpora and spatulate urethral neomeatus if severed part not available. Consider suprapubic tube.

<16-hr cold ischemia
OR
<4-hr warm ischemia
Polyuria

**Common causes:** Diabetes mellitus, diabetes insipidus, medication, hyperparathyroidism, renal disease

**Check labs:** Urinalysis, glucose, BUN, creatinine, calcium

- **Elevated glucose**
  - Diabetes mellitus
  - Medication effect

- **Normal glucose**
  - No medication effect

- **Presence of WBC, leukocyte esterase, nitrates**

- **Diuretics**
  - Lithium
  - Demeclocycline

- **Elevated calcium**
  - Hyperparathyroidism
  - Elevated BUN, creatinine, or abnormal urine sediment

- **Normal calcium**
  - Normal renal tests
  - Suppressed TSH

- **Low urine specific gravity, low urine osmolality, normal serum osmolality, hypernatremia**

- **Diabetes insipidus**

---

876
Precocious Puberty

**Precocious Puberty**

- Signs of secondary sexual development in boys >9 and girls >8

**Common causes:**
- Medication, pituitary tumor, congenital, adrenal hyperplasia, adrenal tumor, ovarian tumor, pseudoprecocious puberty

**X-ray to determine bone age**

- **Bone age > chronologic age**
  - Basal LH levels
  - <5 mIU/mL: GnRH stimulation test, LH, FSH
  - >5 mIU/mL: Gonadotropin-independent (peripheral) precocious puberty
  - Elevated LH, FSH, estradiol, testosterone, TSH, MRI of brain
  - LH, FSH increased
  - Absent LH response

- **Bone age = chronologic age**
  - Incomplete precocious puberty (premature adrenarche or thelarche)

**Gonadotropin-dependent (central) precocious puberty**

- Elevated hCG in β
- Germ cell tumor
- Elevated 17-hydroxyprogesterone
- McCune–Albright syndrome
- Elevates DHEA, DHEAS, findings on imaging

- Congenital adrenal hyperplasia
- Elevated DHEA, DHEAS, findings on imaging
- Adrenal tumor on cancer

**Gonadotropin-independent (peripheral) precocious puberty**

- Very high level of testosterone in β
- Leydig cell tumor
- Elevated testosterone in β and estradiol in β, with bone and skin findings

- Elevated testosterone in β and estradiol in β
- Exogenous sex steroids

**Incomplete precocious puberty**

- Testosterone, estradiol, LH, FSH, cortisol, DHEA, DHEAS, 17-hydroxyprogesterone, hCG (males), abdominal and pelvic US

**Common causes:**
- Medication, pituitary tumor, congenital, adrenal hyperplasia, adrenal tumor, ovarian tumor, pseudoprecocious puberty

**Priapism**

PRIAPISM

- History and physical
  - Duration of erection (treat when >4 hr)
  - Degree of pain
  - Previous history of priapism
  - Use of drugs that may have caused priapism
  - History of pelvic, genital, or perineal trauma
  - History of sickle cell disease
  - History of other hematologic abnormality
  - Labs: CBC, urine analysis, urine toxicology

- Treat any underlying disease, such as sickle cell, simultaneously

- Penile blood gas
- Color duplex US of perineum and penis

- Ischemic:
  - $pO_2 < 30$, $pCO_2 > 60$, $pH < 7.25$ on penile blood gas

- Nonischemic:
  - $pO_2 > 90$, $pCO_2 < 40$, $pH = 7.40$ on penile blood gas

- Place patient on cardiac monitor
- Give dose of Ancef or similar spectrum antibiotic
- Possible dorsal penile back

- Aspiration with or without irrigation
- Phenylephrine 100–500 mcg/mL normal saline

- Distal shunts
- Arteriography and embolization
- Surgical ligation

- Repeal distal shunt or proximal shunt
- Implementation of penile prosthesis controversial

Prostate cancer, rising PSA following androgen ablation (Castration resistant prostate cancer [CRPC]) Rising PSA with testosterone <50 ng/mL

Radiographic evidence of metastasis?

No

Yes

Confirn and maintain castrate testosterone level (<50 ng/mL)

Consider clinical trial

PSADT ≤ 10 mo: Antiandrogen withdrawal
Ketoconazole
Corticosteroids
DES or other estrogen

Periodic radiographic imaging

With radiographic evidence of metastasis treat as mCRPC

PSADT >10 mo: Continue observation

Sipuleucel-T

Antiandrogen withdrawal
Abiraterone
Enzalutamide
Ketoconazole
Corticosteroids
DES or other estrogen
Docetaxel
Clinical trial

If post-docetaxel: Abriraterone, cabazitaxel, radium-223 (symptomatic bone mets)
Salvage chemotherapy
Docetaxel rechallenge
Mitoxantrone
Other secondary hormonal therapy: Antiandrogen, antiandrogen withdrawal, ketoconazole, corticosteroids, DES or other estrogen
Sipuleucel-T
Clinical trial
Best supportive care

Progression

Symptomatic?

No

Yes

Docetaxel
Radium-223 (bone mets only)
Mitoxantrone
Abiraterone
Enzalutamide
Palliative RT or radionuclide for symptomatic bone mets
Clinical trial
Best supportive care

Metastatic castrate resistant prostate cancer (mCRPC)

Confirm and maintain castrate testosterone level (<50 ng/mL)

Denosumab or zoledronic acid with bone metastasis

Clinical trial

Prostatitis

**PROSTATITIS**

- **Prostatitis, general**
  - History and physical
    - Check UA and urine culture
      - Meares–Stamey 4-glass test
      - Suspect acute bacterial prostatitis (NIH I)
        - CBC, admit for IV antibiotics if febrile; treat 4–6 wk oral antibiotics
        - VB1: Initial 5–10 mL
        - VB2: 16 mL midstream voided urine
        - EPS: Expressed prostatic secretions
        - VB3: Post-EPS voided urine
          - All cultures positive
            - Bacterial cystitis. Treat cystitis and repeat test
          - EPS, VB3 culture positive, WBC in EPS
            - Chronic bacterial prostatitis (NIH II)
          - WBC in EPS, culture negative
            - Chronic pelvic pain syndrome inflammatory (NIH IIIa)
          - VB1 cultures positive
            - Urethritis or urethral colonization
          - All cultures negative
            - Chronic pelvic pain syndrome noninflammatory (NIH IIIb)
        - EPS: expressed prostatic secretions
          - NIH: National Institutes of Health classification of prostatitis
          - VB: voided bladder urine
Proteinuria

Common causes: Nephrotic syndrome, diabetes mellitus, multiple myeloma, CHF, medications

Check labs: BUN, creatinine, glucose, serum protein, repeat urine protein

Proteinuria resolved

Fever
Vigorous exercise
Cold exposure
Dehydration

Yes

No

Age <30

Rule out orthostatic proteinuria

Elevated BUN
creatinine

Check: Renal US 24-hr urine for protein and creatinine clearance

Normal renal function

Elevated serum protein

Check labs: serum protein electrophoresis (SPEP)

Glomerular disease
Poly cystic kidney disease
Diabetic nephropathy
Acute tubular necrosis

Nephrotic medications
Renal artery stenosis

Salicylates
Carbamazepine
Aminoglycosides

CHF

Multiple myeloma
Waldenström macroglobulinemia

The use of PSA for prostate cancer screening and the definition of "abnormal" PSA is controversial. No absolute PSA can determine the presence or absence of prostate cancer. Age specific median population values in men:

- 40’s: 0.5–0.7 ng/mL
- 50’s: 0.9 ng/mL
- 60’s: 1.3 ng/mL
- 70’s: 1.7 ng/mL

PSA < 4 ng/mL: 15% prostate cancer risk
PSA 4–10 ng/mL: 30–35% prostate cancer risk
PSA > 10 ng/mL: >67% prostate cancer risk

Screening PSA based on informed consent in an asymptomatic man with >10 yr life expectancy and normal DRE.

Normal or abnormal PSA based on the suspicion of the presence of prostate cancer in a man with or without symptoms (e.g., suspicious rectal exam [nodularity/firmness], proctalgia, pelvic/osteoblastic bone metastasis).

PSA > 1 ng/mL: Repeat every 1–2 yr
PSA < 1 ng/mL: Repeat at age 50
PSA < 3 ng/mL: no other indications for biopsy repeat every 1–2 yr
Any PSA > 3 ng/mL:

Standard transrectal ultrasound (TRUS) directed prostate biopsy for tissue diagnosis (12 core sets and lesion directed).

PSA Adjuncts:
- PSA velocity/PSA density
- % free PSA (<10% suspicious for cancer)
- PCA3 urine score (>35 suspicious for cancer)
- Prostate Health Index (PHI) (>35 suspicious for cancer)

Follow-up based on risk factors:

- Atypia, ASAP, suspicious for cancer
- High-grade PIN in biopsies (≥2 sites)
- Repeat biopsy within 6 mo

Prostate cancer staging and discussion management options (locally advanced vs. metastatic).

After two negative TRUS biopsies, cancer is not commonly found. For repeat biopsy consider anterior and transition zone. Multiparametric MRI and TRUS/MRI fusion biopsy may be useful. High-risk patients may benefit from calculation including transperineal template approaches.
PULMONARY EMBOLISM, DIAGNOSIS

- Clinical signs/symptoms of DVT > Clinical signs/symptoms of DVT
  - Alternate Dx less likely than PE
  - Heart rate >100
  - Immobility/surgery in last 4 wk
  - Previous DVT/PE
  - Hemoptysis
  - Malignancy

Pulmonary Embolism, Diagnosis

D-Dimer

- Normal: PE ruled out
- Elevated (0.5 g/mL): 
  - <2: Low probability
  - ≥2: High probability
  - Consider initiated Tx prior to confirmation

- Clinical signs/symptoms of DVT > Clinical signs/symptoms of DVT
  - Alternate Dx less likely than PE
  - Heart rate >100
  - Immobility/surgery in last 4 wk
  - Previous DVT/PE
  - Hemoptysis
  - Malignancy

- Critically ill: Multidetector CT available
- Not critically ill: Transthoracic/ transesophageal echocardiogram to evaluate for right ventricular strain or dysfunction

- Right ventricular dysfunction seen
- Multidetector CT unavailable
- No dysfunction, no injury
- Dysfunction, no injury
- Dysfunction, and injury

- Admit to inpatient service or consider treatment at home
- Admit to inpatient service anticoagulation
- Consider to admit to ICU. Consider thrombolysis anticoagulation

- Thrombosis, surgery, catheter anticoagulation

- After PE is diagnosed, follow-up and monitor for 2 yr in office, as there is a high rate of recurrence.

Pulmonary Embolism, Treatment

**PULMONARY EMBOLISM, TREATMENT**

Probability of pulmonary embolism above treatment threshold

- IV C filter
  - Yes
  - No
    - Massive pulmonary embolism? (SBP < 90 for > 15 min)
      - Yes
        - Thrombolysis contraindicated?
          - Yes
            - Thrombolysis
          - No
            - No
            - Embolotomy, per local expertise
      - No
        - Evidence of increased severity that suggests potential benefit of thrombolysis:
          - 1. Hemodynamic instability.
          - 2. Worse respiratory insufficiency.
          - 3. Severe RV strain, and/or
          - 4. Major myocardial necrosis?
            - Yes
              - History of heparin-induced thrombocytopenia (HIT)?
                - Yes
                  - Consider fondaparinux or argatroban.
                - No
                  - Absolute contraindications to thrombolysis:
                    - Prior intracranial bleed
                    - Ischemic stroke < 3 mo
                    - Suspected aortic dissection
                    - Active bleeding diathesis
                    - Recent brain or spinal surgery
                    - Closed head or facial trauma
            - No
              - Consider fondaparinux or argatroban.

884
Pyuria

Common causes: Cystitis, pyelonephritis, urethritis, nephritis, appendicitis, vaginal contamination

Check labs: Urine culture

Positive

Fever and/or flank pain
Pyelonephritis

No fever, flank pain
Cystitis

Negative

Acute abdominal pain

Renal disease

Appendicitis
Pelvic inflammatory disease (PID)
Pancreatitis

Glomerulonephritis
Interstitial nephritis

Other infections

Urethritis
Prostatitis
Renal TB

Vaginal contamination
Interstitial cystitis

Rectal Injury

RECTAL INJURY

Rectal injury during radical prostatectomy or radical cystectomy

Identified intraoperatively

Prior pelvic radiation or septic/unstable

No

Immediate layered closure with omental or peritoneal flap

Diverting colostomy, delayed colorectal anastomosis

Cystourethrogram prior to Foley catheter removal; if persistent rectourethral fistula, continue Foley vs. delayed repair (transrectal advancement flap)

Suspected postoperatively

Confirm with distended tender abdomen, fever, elevated WBC, abdomino-pelvic axial imaging with free air and perirectal fluid

Yes

Consider proximal bowel diversion with an end colostomy
Rectocele and Enterocele

**RECTOCELE AND ENTEROCELE**

Rectocele and/or enterocele management (posterior compartment prolapse) based on history, physical exam findings

- **Conservative management**
  - Pelvic floor muscle therapy
  - Pessary
  - If successful, continue management

- **Failure to respond?**
  - Consider surgical approach

- **Surgical approach**
  - Midline fascial plication
  - Site-specific repair
  - Transrectal rectocele repair
  - Graft augmentation
  - Sacral colpopexy with mesh extension

- **Is there occult stress urinary incontinence?**
  - Yes: Consider sling
  - No: Conservative management
Renal Colic Management

RENAL COLIC MANAGEMENT

Helical CT abdomen/pelvis (non-contrast)

CT confirms renal/ureteral stone

Urgent intervention required

Obstructed infected upper tract
impending renal deterioration
intractable pain nausea vomiting
patient preference

Nonurgent pathway

CT shows no renal/ureteral stone

Nonurgent pathway

Consider nonurologic causes

Assess likelihood
of spontaneous
stone passage

Observation

Consider metabolic
stone risk

Intervention required

Assess stone composition,
location, size, upper tract
anatomy, patient preference

Uric acid stone

Dissolution therapy

Consider metabolic
stone risk

Nonuric acid stone

Urologic intervention

Consider metabolic
stone risk

888
Acute kidney injury (AKI, previously called acute renal failure) is an acute loss of kidney function over days to weeks resulting in an inability to excrete nitrogenous wastes and creatinine. Patients are often asymptomatic, and are recognized by an increase in serum creatinine level (>0.5 mg/dL from baseline). Prerenal disease (PD) is one category of AKI where the injury occurs outside the nephron; it is marked by diminished renal blood flow leading to a decrease in glomerular filtration rate (GFR).

Common causes: True volume depletion, hypotension, edematous states, selective renal ischemia, and drugs affecting autoregulation.

Workup: History and physical, serum chemistries, CBC with differential, LFTs including serum albumin urinalysis with microscopy, urine sodium, and creatinine and if diagnosis remains obscure, imaging (x-ray, US, CT).

Volume depletion

Hypotension

Edematous states (decreased effective blood volume)

Selective renal ischemia

Drugs affecting autoregulation

Dehydration/Poor PO intake: Dry mucous membranes, pallor, orthostatic hypotension, weight loss, perspiration, decreased skin turgor.

GI losses: Eructation, diarrhea

Renal losses: Overdiuresis with diuretics, osmotic diuresis with hyperglycemia.

Infectious: Fever, chills, leukocytosis (with left shift).

Hemorrhage

Insensible losses: Perspiration, burns.

Large vessel diseases: Arterial thrombus (hypercoagulable syndromes), emboli (atherosclerotic disease), aortic dissection (connective tissue disease, trauma).

Shock

Septic: Evidence of infection, hypotension, acidosis, constitutional symptoms, leukopenia or leukocytosis, tachycardia, tachypnea.

CHF: JVD, pulmonary rales, pitting edema, hepatomegaly, dyspnea

Cirrhosis: Ascites, varices, pruritus, jaundice, anemia, bruising, edema, elevated LFTs, hypalbuminemia

Nephrotic syndrome: Hypoalbuminemia, proteinuria, foamy urine, hypertension, facial and peripheral edema.

Hepatorenal syndrome: Portal hypertension, oliguria, hyperammonemia, constitutional symptoms

Bilateral renal artery stenosis: Possible history of hypertension, atherosclerosis, fibromuscular dysplasia/worsened by ACE inhibitors or ARBs.

ACE inhibitors: Vasodilation of arterial arterioles

NSAIDs: Vasostenogen of arterial arterioles

Calcineurin inhibitors: Vasostenogen of arterial arterioles

FENa <1% is seen in contrast nephropathy and pigment nephropathy (rhabdomyolysis), both of which cause intrinsic renal failure. FENa can be >1% with diuretics if overdiuresis is severe, and also if prerenal failure develops in patients with chronic kidney disease.

Prerenal disease

Serum BUN: Creatinine ≤20:1

Urine osmolality >400 mOsm

Urine sediment: Bland, few hyaline casts

FENa <1%* (with exceptions)

Intrinsic

Serum BUN: Creatinine >20:1

Urine osmolality 200–300 mOsm

Urine sediment: Variable depending on etiology (eg., acute tubular necrosis [ATN], acute interstitial nephritis [AIN], glomerulonephritis [GN])

FENa >2%*

Postrenal/Obstructive

Urine sediment: Blurred, few hyaline casts, possible RBCs

Anuria if complete bilateral urinary tract obstruction is present.

ACE inhibitors:

Vasodilation of arterial arterioles

NSAIDs:

Vasostenogen of arterial arterioles

Calcineurin inhibitors:

Vasostenogen of arterial arterioles

Renal Mass

**RENAL MASS**

- **Cystic**
  - Bosniak I or II
  - No need to follow if asymptomatic
  - Surveillance with periodic US, CT, or MRI

- **Solid**
  - Bosniak IF
  - Surgical removal
  - Likely RCC, follow with serial imaging and remove as indicated
  - Bosniak III–IV
  - Enhancing >15
  - Concern for metastasis to kidney or lymphoma
  - Fat present
  - MRI if concern for renal vein involvement
  - Staging with imaging of abdomen, chest x-ray, complete metabolic panel

Bosniak Classification:
- I: simple cyst
- II: benign cysts with few thin septae fine calcification in wall
- IF: cysts with increased septae, minimal enhancement or thickened wall. Calcifications present but no soft tissue mass.
- III: thickened, irregular walls or septae with enhancement
- IV: clearly malignant cystic masses (characteristics of Class III with enhancing soft tissue masses)

- **Nephroureterectomy with endoscopic treatment on select cases**
- **TCC**
- **MRI** if concern for renal vein involvement
- **Staging with imaging of abdomen, chest x-ray, complete metabolic panel**

Size <3 cm, advanced age, comorbidities, patient preference

- **Tumor ablation (eg., cryotherapy or radio frequency ablation [RFA])**
- **Active surveillance**
- **Partial nephrectomy**
- **Radical nephrectomy**

Amenable to nephron sparing surgery (eg., Stage T1a [<4 cm] and select T1b [4–7 cm])

- Large tumor, locally invasive, venous involvement, lymphadenopathy, patient preference

Likely AML, follow with serial imaging and remove as indicated

Likely RCC

Diagnostic ureteroscopy or retrograde pyelogram if concern for urothelial carcinoma

Staging with imaging of abdomen, chest x-ray, complete metabolic panel

TCC

Nephroureterectomy with endoscopic treatment on select cases

TCC
RENAL MASS, INTRAOPERATIVE CONSULT

Preop imaging available & enhancing solid mass:
1. Evaluate contralateral kidney with available labs/imaging ± IRBx & FS
2. Attempt to perform PN after family discussion (if present)

Preop imaging unavailable, patient stable:
• Obtain Doppler US

Solid elements, normal contralateral kidney, and amenable to PN
• Perform PN

Radical required for technical reasons

RN required for technical reasons: perform if evidence of normal contralateral kidney function and:
1. Absolute indication for RN (≥cT3, vascular compromise, adjacent organ involvement)
2. After IRBx and FS show evidence of malignancy

Evidence of benign disease, severe CKD, and/or abnormal contralateral kidney function
• Defer treatment until discussion of risk of dialysis

Abbreviations:
- RN = radical nephrectomy
- PN = partial nephrectomy
- IRBx = intraop renal biopsy
- FS = frozen section analysis
- CKD = chronic kidney disease
Renal Trauma, Hemodynamically Stable

**RENAL TRAUMA, HEMODYNAMICALLY STABLE**

- CT abdomen/pelvis with delayed images

- **Grade I–III**
  - Nonoperative management:
    - Observation
    - Bed rest until gross hematuria resolves
    - Serial hematocrit
  - Repeat CT at 36–72 hr for grade IV nonvascular
  - Place ureteral stent for significant enlarging urinoma
  - Continued observation and reimaging with possible surgical repair if persistent

- **Grade IV nonvascular**
  - Nonoperative management:
    - Observation
    - Bed rest until gross hematuria resolves
    - Serial hematocrit
  - Englarging hematoma CT or >4–6 units pRBCs required for declining hematocrit
  - Selective angioembolization and continued observation

- **Grade IV vascular and any grade V**
  - Operative management generally required for pedicle avulsion injuries
  - Long-term BP monitoring
  - Repeat angioembolization or surgical repair if continued bleeding

- **Grade IV nonvascular**
  - Observation
  - Bed rest until gross hematuria resolves
  - Serial hematocrit
  - Repeat CT at 36–72 hr for grade IV nonvascular
  - Place ureteral stent for significant enlarging urinoma
  - Continued observation and reimaging with possible surgical repair if persistent

- **Repeat CT at 36–72 hr for grade IV nonvascular**
  - Englarging hematoma CT or >4–6 units pRBCs required for declining hematocrit
  - Selective angioembolization and continued observation

- **Long-term BP monitoring**
  - Repeat angioembolization or surgical repair if continued bleeding

**CT abdomen/pelvis with delayed images**
**SCROTUM AND TESTICLE, MASS**

- **History and physical**
  - If trauma, suspect testis fracture or hematoma
  - Painful and suspect torsion
    - Bilateral orchiopexy
  - Not painful and/or torsion not suspected
    - Scrotal US with Doppler
  - Inguinal hernia
    - Surgical repair
  - Abscess
    - Surgical
  - Epididymo-orchitis
    - Anti-inflammatories
    - Antibiotics
    - Rare surgical excisions
  - Torsion of testicular
    - Hydrocele
    - Surgical repair or observation
  - Epididymal mass
    - Cystic
    - Spermatocele, epididymal head
    - Labs: LDH, AFP, β-hCG, LFTs, CBC, Cr
    - Chest x-ray
    - Consider CT abdomen with IV/PO contrast preoperatively, but can also be done postoperatively
  - Solid testicular mass
    - Cystic
    - Solid
  - Spermatic cord mass
    - Cystic
    - Varicocele
    - Radical inguinal orchiectomy with high litigation of spermatic cord
SCROTUM AND TESTICLE, TRAUMA

History and physical
Type of injury
Other injuries
Urine analysis

Blunt

Physical exam suggestive of testicular injury

Penetrating

Immediate surgical repair with goal of testis salvage

If presence of hematuria, consider associated urethral injury

Scrotal US with Doppler

Presence of:
- Testicular fracture
- Inhomogeneity of testicular parenchyma
- Occlusion of tunica albuginea
- Testicular torsion
- Intratesticular hematoma
- Large or expanding hematocoele
Testis Cancer, Nonseminoma

TESTIS CANCER, NONSEMINOMA

Testis Cancer, nonseminomatous Germ cell tumor

Stage 1

RPLND vs. surveillance vs. chemotherapy

Presence of: 
- >T2 
- >40% embryonal 
- Lymphatic or vascular invasion

Primary chemotherapy

Template vs. bilateral RPLND

Stage IIA-III

Primary RPLND

Stage IIC-III or stage IV

Primary chemotherapy based on risk category: Good, intermediate, and poor

Complete response on imaging

Partial response on imaging and markers normal

Poor response on imaging and/or markers elevated

Observation

Bilateral RPLND

Salvage chemotherapy

Tumor in specimen

Teratoma

Fibrosis

Salvage chemotherapy based on tumor left behind

Observation

NO

N1

≥N2

Observation

Adjuvant chemotherapy

Bilateral RPLND

Salvage chemotherapy
Testis Cancer, Seminoma

**TESTIS CANCER, SEMINOMA**

CT abd/pelvis
AFP (5 wk postorchietomy)
hCG (1 wk postorchietomy)
Chest x-ray
Chest CT if x-ray abnormal

Pure seminoma

Stage I
- Spermatocytic seminoma
  - Observation
  - Tumor <4 cm
    - No vascular or lymphatic invasion
      - Observation
      - Relapse
      - Radiation therapy
      - Chemotherapy
    - Tumor >4 cm
      - Vascular or lymphatic invasion
      - Low-dose radiation therapy or investigational chemotherapy
      - Relapse
      - Chemotherapy
      - Relapse

Stage IIA and IIB
- Classic and anaplastic seminoma
  - Observation
  - Elevated hCG
  - Chemotherapy

Stage IIC and III
- Radiation therapy
  - Residual mass
  - Consistent with desmoplastic response
    - Observe

Platinum-based chemotherapy

Tumor >4 cm
- Vascular or lymphatic invasion
  - Low-dose radiation therapy or investigational chemotherapy
  - Relapse
  - Chemotherapy

Tumor <4 cm
- No vascular or lymphatic invasion
  - Observation
  - Relapse
  - Radiation therapy

Consistent with desmoplastic response
- Observe

Discrete mass >3 cm:
- Surgical resection

Necrosis/fibrosis
- Germ cell
  - Salvage chemotherapy or XRT

Necrosis/fibrosis
- Germ cell
  - Salvage chemotherapy or XRT

Pure seminoma

AFP (5 wk postorchietomy)
Chest x-ray
Chest CT if x-ray abnormal

Chest CT if x-ray abnormal
**Testosterone Deficiency (Hypogonadism)**

**TESTOSTERONE DEFICIENCY (HYPOGONADISM)**

- Clinical suspicion of testosterone deficiency
  - Metabolic syndrome
  - Erectile dysfunction
  - Clinical symptoms or physical signs

Measure morning total testosterone (7–11 AM)

- <300 ng/dL
  - Repeat morning total testosterone (consider free or bioavailable T if suspect altered SHBG)
  - Low testosterone
  - Exclude reversible causes: illness, medications, nutritional deficiency
  - Measure: FSH, LH, SHBG
  - Low testosterone
  - Normal testosterone
  - Elevated LH and FSH

Low testosterone

- Primary hypogonadism: Congenital anorchidism, cryptorchidism, mumps orchitis; genetic and developmental conditions (Klinefelter syndrome, Sertoli cell only syndrome, etc.); radiation treatment, chemotherapy, testicular trauma

Secondary hypogonadism: Genetic conditions (Kallmann syndrome, Prader-Willi syndrome), Pituitary (tumors, granulomas, abscesses), Hyperprolactinemia, cranial trauma or radiation, medications

Mixed (primary and secondary) hypogonadism

Undescended Testicle (Cryptorchidism)

**UNDESCENDED TESTICLE (CRYPTORCHIDISM)**

- Tests exam by experienced observer

**Nonpalpable**
- Consider US
  - Overweight
  - Uncooperative

**Palpable**
- Retractile
- Distal to external ring

**Large contralateral testis >2 SD**
- No palpable appendage
- Scrotal nubbin
  - Consider scrotal orchidopexy

**Normal contralateral testis**
- No intrascrotal structures
- Yearly exams and parental observation
- Inguinal orchidopexy with or w/o hernia repair

**Inguinal orchiectomy**
- Hyptrophic, short vas, dysgenetic, or postpubertal
  - 1- or 2-stage Fowler–Stephens orchidopexy
  - Laparoscopic orchidopexy

**Consider contralateral testicular fixation**
- No further intervention
- Inguinal exploration
  - Viable testis
  - Consider microvascular orchidopexy
  - Laparoscopic orchidopexy
  - 1- or 2-stage Fowler–Stephens orchidopexy
  - Hypotrophic, short vas, dysgenetic, or postpubertal

**Inguinal repair**
- Laparoscopy
  - Long-term F/U Counseling the family and self-exam

**Patent PV**
- Distal to external ring
- Consider scrotal orchidopexy

**Consider staged approach**
- Yearly exams and parental observation
- Inguinal orchidopexy with or w/o hernia repair
- Patent PV

Urethral Discharge

URETHRAL DISCHARGE

Common causes:
Gonorrhea, chlamydia, trichomonas, urethral strictures, reactive arthritis (formerly Reiter's syndrome)

Check labs: Culture or urine DNA probe for GC and chlamydia, wet mount

+ STI/STD test

Gonorrhea
Chlamydial infection
Trichomoniasis

- STI/STD test

Joint pains
Urethral stricture

+ PPD

Reactive arthritis
(Formerly Reiter syndrome)
Undifferentiated spondyloarthropathy

Tuberculosis

Urinary Retention, Male

**Suspect acute bacterial prostatitis:**
- Suprapubic catheter preferred if septic

**History and physical exam:**
- LUTS history
- Urologic surgery
- Diabetes, neurologic conditions
- History of strictures, STDs
- Neurologic exam
- GU exam including DRE
- Medication history
- Bladder sonogram/scan

**Neurologic findings concerning for cord compression (ie, due to prostate cancer or other CNS lesion):**
- Foley catheter placement
- MRI or CT scan of spine
- Neurosurgery consultation

**Drain bladder:**
- Larger or coude type catheters may be needed
- Cystoscopy with placement of catheter over wire

**Bladder drained:**
- Record initial output
- Send urine analysis and culture
- Send electrolytes, CBC

**Stop possible precipitating medications**
Start α-blocker therapy
Consider starting 5α-reductase inhibitor
Course of antibiotics if suspect infection

**Voiding trial in 1–2 wk**

**Pass:**
- Continue medical management for presumed BPH
- Surgery if indicated for BPH
- Check PSA in 4–6 wk and consider prostate cancer as cause

**Fail:**
- Further evaluation options: Cystoscopy, urodynamics, imaging, PSA
- Consider prostate cancer
- Treat as indicated: Clean intermittent catheterization, surgery, sacral

**Suspect urethral stricture:**
- Attempt smaller catheter
- Obtain RUG or perform cystoscopy to confirm
- Suprapubic tube preferred over repeated dilation

**Suspect prostate cancer:**
- Obtain PSA
- Bone scan and CT scan if indicated

**Bladder drained:**
- Record initial output
- Send urine analysis and culture
- Send electrolytes, CBC

**Stop possible precipitating medications**
Start α-blocker therapy
Consider starting 5α-reductase inhibitor
Course of antibiotics if suspect infection

**Voiding trial in 1–2 wk**

**Pass:**
- Continue medical management for presumed BPH
- Surgery if indicated for BPH
- Check PSA in 4–6 wk and consider prostate cancer as cause

**Fail:**
- Further evaluation options: Cystoscopy, urodynamics, imaging, PSA
- Consider prostate cancer
- Treat as indicated: Clean intermittent catheterization, surgery, sacral

**If acute renal failure, electrolyte abnormalities, or no urinary output for >24 hr consider admission for monitoring of electrolytes and postobstructive diuresis**
Urine Leak From Vagina

**URINE LEAK FROM VAGINA**

Urine leakage from vagina (vesicovaginal and ureterovaginal fistula)

- Cystoscopy, retrograde pyelogram or CT–IV urogram

Ureter unobstructed

- Cystoscopy, bladder distention, dye test
- Confirm vesicovaginal fistula
- Surgical repair

Ureter obstructed

- Retrograde ureterogram/pyelogram
- Confirm ureteral obstruction and/or leakage
- Attempt to pass ureteral catheter

Successful

- Observe

- Fistula repairs naturally

Unsuccessful

- Fistula remains patent

- Ureteroneocystostomy
Urolithiasis

Common causes: Idiopathic, gout, medication effect, hyperparathyroidism, renal disease, colitis

Stone analysis if possible to determine diagnosis

No stone available

Medication effect

Diuretics
Calcium antacids, Indinavir

No medication effect

Check labs: Electrolytes, BUN, creatinine, calcium, uric acid, urine for calcium, oxalate, acid, uric acid

Serum calcium elevated

Parathyroid hormone (PTH) elevated

Hyperparathyroidism

Urine uric acid and/or serum uric acid

Elevated

Normal

Gout
Acidic urine

Urine calcium level

Elevated

Normal

Idiopathic stone formation

Colitis
Chronic diarrhea

Renal disease

Polygenic kidney disease
Renal tubular acidosis

Urolithiasis, Ureteral Calculi

**UROLITHIASIS, URETERAL CALCULI**

- **History and physical**
- **Urine analysis**
- **CBC**
- **Basic metabolic panel**
- **CT scan without contrast**

**Signs of sepsis**

**Proximal ureter**
- Stone <10 mm
  - Symptomatic controlled
  - Normal contralateral kidney function
  - Patient preference

**Distal ureter**
- Stone removal indicated:
  - Persistent obstruction
  - Failure of stone progression
  - Uncontrolled pain

- **Trial of medical expulsive therapy:**
  - α-blocker preferred
  - Periodic imaging

- **Mid ureter**
  - >10 mm
  - <10 mm

- **ESWL may be preferred over ureteroscopy**
- **ESWL or urerteroscopy acceptable**

- **Ureteroscopy may be preferred over ESWL. If uncomplicated, may omit ureteral stent placement**

- **Urgent percutaneous drainage or ureteral stenting with delayed definitive treatment**

UTI, Adult Female

**UTI, ADULT FEMALE**

Complicating factors for UTI & pyelonephritis treatment
- Women >55 yrs
- Symptoms lasting >7 days
- Diabetes mellitus
- Structural abnormality of urinary tract (eg, renal calculi, tumor, abscess)
- Spinal cord injury
- Multiple sclerosis
- Pregnancy
- Chronic catheterization
- Recurrent UTI

Signs and symptoms of suspected UTI
- Dysuria in combination with frequency, urgency, suprapubic pain, and/or hematuria
- Usually in the absence of vaginal symptoms
- Pyuria on routine urinalysis
- Nitrite positive (for gram negatives)

Presence of additional signs & symptoms?
- Fever (Temperature ≥38.5°C)
- Flank pain
- Abdominal or pelvic pain
- Nausea/vomiting
- Costovertebral tenderness

UTI unlikely
- Pelvic exam to detect vaginal or cervical infection; consider urine culture

History and physical most consistent with UTI
- Dipstick UA shows leukocyte esterase or nitrites
- Microscopic UA
  - >15 WBC/HPF
  - >5 RBC/HPF (or not available)

Empiric antibiotics: 3 day regimen
- trimethoprim/sulfamethoxazole
- ciprofloxacin
- nitrofurantoin

Consider urine culture, cervical culture or KON or wet mount to detect other diagnoses (vaginal infection, chlamydia, etc.). Need follow-up for clearing of hematuria

UTI, Pediatric

**UTI, PEDIATRIC**

- History and physical
- Urine analysis and culture
- Antibiotics
- Voiding cystourethrogram (VCUG) and renal/bladder ultrasound (RUS) after

**Renal VCUG and RUS**

**Vesicoureteral reflux**

**Hydronephrosis**

- Observe and if recurrent UTIs:
  - Nuclear VCUG may be more sensitive in detecting VUR
  - Manage constipation and dysfunctional voiding
  - Consider prophylactic antibiotics if UTIs continue and no abnormalities
  - Consider PICC if recurrent febrile UTIs

- Prophylactic antibiotics
  - Treat dysfunctional voiding and constipation.
  - Consider DMSA scan, serum creatinine if febrile UTIs and/or hypertension.

- Rule out secondary causes of VUR:
  - Dysfunctional voiding
  - Posterior urethral valves
  - Neurogenic bladder

**UPJ obstruction**

- Ureterocoele
- Ectopic ureter
- Megareuter
- Prune belly syndrome
- Posterior urethral valves

**Recurrent UTIs**

- Evidence of further renal scarring
- Parent preference for surgery
- Reflux nephropathy
- Elevated creatinine
- Noncompliance

**Principles of Management:**
- VUR often resolves spontaneously for grades I–III VUR
- The higher the grade of VUR, the less likely it will spontaneously resolve
- Prophylactic antibiotics are generally benign and are 1st-line therapy

**Absent**

- Recurrent UTIs
- Evidence of further renal scarring
- Parent preference for surgery
- Reflux nephropathy
- Elevated creatinine
- Noncompliance

- Continue antibiotics and follow with interval VCUG (nuclear or fluoroscopic) until reflux resolves and no more UTIs

**Present**

- Surgical correction of VUR
  - Open

- Document resolution of VUR with VCUG (nuclear or fluoroscopic)
VAGINAL BLEEDING, ABNORMAL

Common causes: PCOS, uterine polyp, uterine tumor, infection, cervical pathology, luteal phase defect

Prepubescent

Child abuse, tumor, anovulatory bleeding of adolescence

Reproductive age

Obtain US, FSH, TSH, prolactin, coagulation studies

Obtain HCG, genital cultures

Workup normal

Pelvic exam, Pap, genital C/S, US and/or endometrial biopsy: TSH, prolactin

Postmenopausal

Common causes: PCOS, uterine polyp, uterine tumor, infection, cervical pathology, luteal phase defect

Ovulatory

Obtain US, FSH, TSH, prolactin, coagulation studies

Hypothyroidism

Normal

Weight loss, excessive exercise

Hyperprolactinemia

Abnormal

Anorexia nervosa

Pituitary adenoma

Yes

Check: LH, DHEA-S, endometrial biopsy

No

Bulimia

Anorexia nervosa

Polycystic ovary syndrome

Uterine tumor

Regular bleeding at cycles >35 days

Regular bleeding at cycles <21 days

Cervical pathology

Menorrhagia

Regular bleeding between 21 and 35 days

Luteal phase defect

Oligomenorrhea

Uterine tumor

Bleeding disorder

Yes

No

Anovulatory

Age >35 yr

Check: Endometrial biopsy, CBC, PT/PTT

907
Vaginal Discharge

VAGINAL DISCHARGE

Common causes: Bacterial vaginosis, candida vulvovaginitis, trichomoniasis

Less common causes: Atrophic vaginitis, cervicitis, foreign body, irritants, and allergens

History and pelvic exam

Vulvar or vaginal lesions/abnormalities (consider carcinoma)

Foreign body

Check pH*

pH < 4.5

Wet prep with KOH

Clue cells

Consider atrophic vaginitis, erosive lichen planus, lichen sclerosus, pemphigoid, or desquamative inflammatory vaginitis

pH > 4.5

Wet prep

PMNs

Motile flagella

Trichomoniasis

Culture for N. gonorrhoeae and chlamydia

Metronidazole 2 g × once OR 500 mg PO b.i.d. × 7 days

Candida vulvovaginitis

Fluconazole 150 mg PO × once

Hyphae or budding yeast

Yes

Consider physiologic leukorrhea, contact irritant, seborrheic dermatitis, psoriasis

No

Cervicitis

Clue cells +/- KOH "whiff" test

Bacterial vaginosis

Metronidazole 500 mg PO BID × 7 days OR Clindamycin 2% cream 5 g QHS × 7 days

* pH for diagnosis is less useful for women at the extreme ages

**VAS DEFERENS, CONGENITAL ABSENCE**

- Nonpalpable vas deferens
- Vas deferens absent unilaterally
  - Cystic fibrosis evaluation of patient CFTR (cystic fibrosis transmembrane conductance regulator) gene analysis
    - Negative for cystic fibrosis trait
      - Evaluate cystic fibrosis status of partner
        - Partner negative for cystic fibrosis
          - In vitro fertilization via surgical sperm extraction/aspiration
        - Partner positive for cystic fibrosis
          - Counsel patient and partner about cystic fibrosis
    - Positive for cystic fibrosis trait
      - Renal US CFTR testing

Vitamin D Deficiency

**VITAMIN D DEFICIENCY**

Risk factors/common causes:
- Age >65
- Insufficient sunlight exposure (homebound, veiled)
- Renal disease
- Liver disease
- Depression
- Chronic use of anticonvulsants
- Dark skin
- Insufficient dietary intake
- GI malabsorption
- Obesity (BMI >30)
- Immigrants to colder climates
- Chronic use of glucocorticoids
- Periosteal bone pain (eg., sternum, ilia)
- GI malabsorption:
  - Celiac, cystic fibrosis,
  - Inflammatory bowel disease
- Pregnancy
- Medications: Anticonvulsants, antiretroviral
  and glucocorticoids
- Gastrectomy or extensive bowel surgery

**Infants and children:**
- <1 y/o: 400 IU (D) per day
- >1 y/o: 400–1,000 IU (D) per day + adequate sun exposure (5–30 minutes twice weekly depending on time of day, between 10 AM and 3 PM and skin pigmentation)
- Infants >1 y/o with ‘Obesity or Malabsorption Syndrome’, consider pediatric endocrine evaluation; if unavailable, 5,000 units/day for 2 mo; if labs are normal/normal physical exam and normal x-ray. Maintenance dose: 600 units/day

**Significant risk factors?**
- Level <20 ng/mL (vitamin D deficiency)
- Treatment: Start 50,000 IU (D2 or D) once per week for 8 wk, then 1,000–4,000 IU per day thereafter
- Then 1,000 IU (D) per day thereafter
- After 6 mo, consider repeating serum 25 OH vitamin D level

- Level <20 ng/mL (vitamin D deficiency)
- Consult endocrinology if no malabsorptive disease

**Lab: Serum 25-hydroxyvitamin D concentration**
- Level >30 ng/mL normal
- Level <30 ng/mL (vitamin D insufficiency)
- Treatment: 800–1,000 IU (D) per day
- Maintenance: 800–1,000 IU (D) per day

- Level <20 ng/mL (vitamin D deficiency)
- Treatment: Start 50,000 IU (D2 or D) once per week for 8 wk, then 1,000–4,000 IU per day thereafter
- Then 1,000 IU (D) per day thereafter
- After 6 mo, consider repeating serum 25 OH vitamin D level

- Level <20 ng/mL (vitamin D deficiency)
- Consult endocrinology if no malabsorptive disease

SECTION IV
Urinalysis and Urine Studies

Section Editor: Leonard Gomella, MD, FACS
I. URINE ANALYSIS

URINE ANALYSIS PROCEDURE

For a routine urine analysis, a fresh (<1 hr old), clean-catch urine sample is acceptable. If the analysis cannot be performed immediately, refrigerate the sample. (When urine stands at room temperature for a long period, casts and red blood cells undergo lysis, and the urine becomes alkalized with precipitation of salts.)

1. Pour 5–10 mL of well-mixed urine into a centrifuge tube.
2. Check for appearance (color, turbidity, odor). If a urine sample looks grossly cloudy, it is sometimes advisable to examine an unspun sample. If an unspun sample is used, make note that you have done so. In general, for routine urine analysis, an unspun sample is more desirable.
3. Spin a capped sample at 3,000 rpm for 3–5 min.
4. While the sample is in the centrifuge, use the dipstick (Chemstrip, etc.) to perform the dipstick evaluation on the remaining sample. Read the results according to the color chart on the bottle. Allow the correct amount of time before reading the test (usually 1–2 min) to avoid false results. Chemstrip 10 provides 10 tests (specific gravity, pH, leukocytes, nitrite, protein, glucose, ketones, urobilinogen, bilirubin, and blood). Other strips may provide more agents. Agents that color the urine red, phenoxyethylparaben (p-hydroxyacetanilide) may interfere with the reading. Dipstick specific gravity is also available on some assay strips.
5. Decant and discard the supernatant. Mix the remaining sediment by flicking it with your finger and pouring or pipetting 1 or 2 drops onto a microscopic slide. Cover with a coverslip. Compare with a normal urine.
6. Examine 10 low-power fields (×150, i.e., 10× objective for epithelial cells, casts, crystals, and mucus. Casts are usually reported as number of low-power fields and tend to collect around the periphery of the coverslip.
7. Examine several high-power fields (×400, i.e., 40× objective) for epithelial cells, crystals, RBCs, WBCs, bacteria, amorphous substances (all usually unimportant). RBCs, WBCs, and bacteria are usually reported as number per high-power field.

Normal Urine Analysis Values

- Appearance: Yellow, clear, straw-colored
- Specific gravity: Normal: 1.012
- pH: Normal: 6.0–7.5
- Glucose: 0–4/HPF
- Protein: 0–4/HPF
- Leukocyte esterase: Negative
- Blood: Negative
- Nitrite: Negative
- WBC: 0–4/HPF
- RBC: 0–4/HPF
- Epithelial cells: Occasional
- Mucus: Occasional
- Bacteria: None

Differential Diagnosis for Routine Urine Analysis

- Appearance (see Section II Urine, Abnormal Color; Section IV, Urine, Odor, and Urine, Particles in)
  - Acidic: High-protein (meat) diet, ammonium citrate, methicillin, and other medications (due to ketoacidosis [starvation, diabetes], chronic obstructive pulmonary disease [COPD]),
  - Basic: Urate uric acid infections (UTI), renal tubular acidosis, diet (high-vegetable, milk, immediately after meal), sodium bicarbonate therapy, vomiting, metabolic alkalosis, diabetic therapy
- Specific gravity:
  - Usually strongly to slightly, except with osmotic diuresis. A value <1.012 indicates normal renal concentrating ability:
    - Increased: Volume depletion, congestive heart failure (CHF), adrenal insufficiency, diabetes mellitus, inappropriate antidiuretic hormone (ADH), increased proteins (nephrosis); if markedly increased (1.040–1.050), suspect artifact or excretion of radiographic contrast media
    - Decreased: Diabetes insipidus, pheochromocytoma, glomerulonephritis, water load with normal renal function
- Bilirubin:
  - Positive: Obstructive jaundice (myeloproliferative and metastatic), hepatitis (Note: False positive with stool contamination)
- Blood:
  - Positive: See Section I Hematuria, gross and microscopic, adult and Hematuria, microscopic, pediatric
  - Note: If the dipstick is positive for blood, but no RBCs are seen, free hemoglobin may be present from trauma, from a transfusion reaction, or from lysis of RBCs (RBCs will lysis if the pH is <5.0 or >8.0); or there may be myoglobin present because of a crush injury, burn, or tissue ischemia.
- Ketones:
  - Detects primarily acetone and acetoacetic acid and not by hydroxybutyric acid
  - Positive: Starvation, high-fat-low-carbohydrate diet, diabetic ketoacidosis, vomiting, diarrhea, hyperthyroidism, pregnancy, fatty livers (especially in children)
- Glucose:
  - Positive: Fructose, lactose, sucrose, alcohol, urine
  - Negative: Fructose, lactose, alcohol, urine
- Nitrates:
  - Detects primarily potassium nitrate and potassium nitrate
  - Positive: Infection (A negative test does not rule out infection, because some organisms, such as Shigella flexneri and other gram-positive cocci), will not produce nitrates, and the urine must also be retained in the bladder for several hours to allow the bacteria to take place)

- Protein:
  - Indicated by dipstick of persistent proteinuria
- Leukocyte esterase
  - Positive: Pyelonephritis, glomerulonephritis, Kimura disease, nephrotic syndrome, myeloma, polycystic disease, colic stone ingestion, and malignancies of the lower tract, functional causes (fever, stress, heavy exercise), malignant hypertension, congestive heart failure
- Urobilinogen
  - See Section I Pyuria:
  - This test detects ≤1 WBC/HFP if voided WBCs. When combined with the nitrite test, it has a predictive value for UTI of 74% if both tests are positive, and >97% if both tests are negative
  - Positive: Infection (false-positive with vaginal contamination)
- Urobilin
  - Positive: Cholestasis, CHF with hepatic congestion, nephritis, hyperthyroidism, suppression of gut flora with antibiotics (Note: With obstructive jaundice, urobilinogen is usually normal, but bilirubin is elevated)
- Leukocytes
  - Positive: Glaucoma, fracture, gout, sarcoidosis
- Leukocyte esterase
  - Positive: Pyelonephritis, urinary tract infections (UTI), renal tubular acidosis, diet (high-vegetable, milk, immediately after meal), sodium bicarbonate therapy, vomiting, metabolic alkalosis, diabetic therapy
- Blood
  - Positive: Pyelonephritis, urinary tract infections (UTI), renal tubular acidosis, diet (high-vegetable, milk, immediately after meal), sodium bicarbonate therapy, vomiting, metabolic alkalosis, diabetic therapy
- Nitrite
  - Positive: Infection (A negative test does not rule out infection, because some organisms, such as Shigella flexneri and other gram-positive cocci), will not produce nitrates, and the urine must also be retained in the bladder for several hours to allow the bacteria to take place)
- Protein
  - Indicated by dipstick of persistent proteinuria
- Leukocyte esterase
  - Positive: Pyelonephritis, glomerulonephritis, Kimura disease, nephrotic syndrome, myeloma, polycystic disease, colic stone ingestion, and malignancies of the lower tract, functional causes (fever, stress, heavy exercise), malignant hypertension, congestive heart failure
- Urobilinogen
  - See Section I Pyuria:
  - This test detects ≤1 WBC/HFP if voided WBCs. When combined with the nitrite test, it has a predictive value for UTI of 74% if both tests are positive, and >97% if both tests are negative
  - Positive: Infection (false-positive with vaginal contamination)
- Urobilin
  - Positive: Cholestasis, CHF with hepatic congestion, nephritis, hyperthyroidism, suppression of gut flora with antibiotics (Note: With obstructive jaundice, urobilinogen is usually normal, but bilirubin is elevated)
- Leukocytes
  - Positive: Glaucoma, fracture, gout, sarcoidosis
- Leukocyte esterase
  - Positive: Pyelonephritis, urinary tract infections (UTI), renal tubular acidosis, diet (high-vegetable, milk, immediately after meal), sodium bicarbonate therapy, vomiting, metabolic alkalosis, diabetic therapy
- Blood
  - Positive: Pyelonephritis, urinary tract infections (UTI), renal tubular acidosis, diet (high-vegetable, milk, immediately after meal), sodium bicarbonate therapy, vomiting, metabolic alkalosis, diabetic therapy
- Nitrite
  - Positive: Infection (A negative test does not rule out infection, because some organisms, such as Shigella flexneri and other gram-positive cocci), will not produce nitrates, and the urine must also be retained in the bladder for several hours to allow the bacteria to take place)
II. SPOT OR RANDOM URINE STUDIES

The so-called spot urine is often ordered to aid in diagnosing various conditions. It relies on only a small sample (10–20 mL) of urine:

- **Spot urine for Jβ/microglobulin (<0.3 mg/L):** A marker for renal tubular injury.
- **Increased:** Diseases of the proximal tubule (ATN, interstitial nephritis, pyelonephritis), drug-induced nephropathy (aminoglycosides), diabetes, trauma, sepsis.

- **Spot urine for electrolytes:** The serum levels of this assay is limited because of large variations in daily fluid and salt intake, and the results are usually underestimated if a diuretic has been given. (See section III. eGFR and other factors such as age, sex, and race and has generally replaced 24-hr urinary creatinine determinations. Online calculators for adults and children can be found at: http://clinical.niddk.nih.gov/lab-evaluation/calculators.html. (Accessed April 19, 2014)

- **Spot urine for creatinine:** A marker of renal tubular injury.
- **Increased:** Dehydration, CHF, hypercalcemia, hypothyroidism, interstitial nephritis, pyelonephritis, diabetes mellitus, nephrotoxin, virus.
- **Granular casts:** Breakdown of cellular casts leads to waxy casts; dirty brown granular casts typical in the early morning.

- **Spot urine for osmolality:** (Present with Hansell/Wright staining and white light microscopy):
  - **Increased:** Diabetes insipidus, acute renal failure, medications (azathioprine, indinavir, itraconazole).
  - **Decreased:** Nephrogenic diabetes insipidus, acute tubular necrosis, DI within the context of diabetes insipidus, SIADH, acute tubular necrosis, nephrogenic diabetes insipidus.

- **Spot urine for myoglobin:** (qualitative negative): Positively; skeletal muscle conditions (crush injury, etc.). If the values in the previous example were for a 12-hr-old boy who weighed 70 lb (1.1 m2), the clearance would be: 70 mL/min (1.1 m2) × 7.1 mL/min = 75 mL/min.

III. CREATININE CLEARANCE AND GLOMERULAR FILTRATION RATE

**CREATININE CLEARANCE**

- **Renal male:** Total creatinine 1–2 g/24 h (8.8–17.7 mmol/L), clearance 85–125 mL/min/1.73 m2.
- **Renal female:** Total creatinine 0.8–1.8 g/24 h (7.1–15.9 mmol/L); clearance 75–115 mL/min/1.73 m2.
- **Child:** Total creatinine (3 yr) 12–10 mg/kg/24 h (1.08–1.44 mL/min/1.73 m2).
- **Decreased:** A decreased creatinine clearance results in an increase in serum creatinine, usually secondary to renal insufficiency. See Section II. Filtration Rate.

**DETERMINATION OF CREATININE CLEARANCE**

- **Creatinine clearance (CrCl):** A measure of the glomerular filtration rate (GFR) in the absence of renal disease.

- **Increased:** Early diabetes mellitus, pregnancy

**Estimated glomerular filtration rate (eGFR):**

**Estimated glomerular filtration rate (eGFR):**

**Estimated glomerular filtration rate (eGFR):**

- **Creatinine clearance:** A marker of renal tubular injury.
- **Increased:** Dehydration, CHF, hypercalcemia, hypothyroidism, interstitial nephritis, pyelonephritis, diabetes mellitus, nephrotoxin, virus.
- **Granular casts:** Breakdown of cellular casts leads to waxy casts; dirty brown granular casts typical in the early morning.

- **Spot urine for protein:** (Present with Hansell/Wright staining and white light microscopy):
  - **Increased:** Diseases of the proximal tubule (ATN, interstitial nephritis, pyelonephritis), drug-induced nephropathy (aminoglycosides), diabetes, trauma, sepsis.

- **Spot urine for electrolytes:** The serum levels of this assay is limited because of large variations in daily fluid and salt intake, and the results are usually underestimated if a diuretic has been given. (See section III. eGFR and other factors such as age, sex, and race and has generally replaced 24-hr urinary creatinine determinations. Online calculators for adults and children can be found at: http://clinical.niddk.nih.gov/lab-evaluation/calculators.html. (Accessed April 19, 2014)

- **Spot urine for creatinine:** A marker of renal tubular injury.
- **Increased:** Dehydration, CHF, hypercalcemia, hypothyroidism, interstitial nephritis, pyelonephritis, diabetes mellitus, nephrotoxin, virus.
- **Granular casts:** Breakdown of cellular casts leads to waxy casts; dirty brown granular casts typical in the early morning.

- **Spot urine for osmolality:** (Present with Hansell/Wright staining and white light microscopy):
  - **Increased:** Diabetes insipidus, acute renal failure, medications (azathioprine, indinavir, itraconazole).
  - **Decreased:** Nephrogenic diabetes insipidus, acute tubular necrosis, DI within the context of diabetes insipidus, SIADH, acute tubular necrosis, nephrogenic diabetes insipidus.

- **Spot urine for myoglobin:** (qualitative negative): Positively; skeletal muscle conditions (crush injury, etc.). If the values in the previous example were for a 12-hr-old boy who weighed 70 lb (1.1 m2), the clearance would be: 70 mL/min (1.1 m2) × 7.1 mL/min = 75 mL/min.

**Estimated glomerular filtration rate (eGFR):**

**Estimated glomerular filtration rate (eGFR):**

- **Creatinine clearance:** A measure of the glomerular filtration rate (GFR) in the absence of renal disease.

- **Increased:** Early diabetes mellitus, pregnancy

**DETERMINATION OF CREATININE CLEARANCE**

- **Creatinine clearance (CrCl):** A sensitive indicator of early renal insufficiency and is a measure of the glomerular filtration rate (GFR); however, the GFR does not provide information on the vogue of the renal disease. CrCl decreases with age, with a CrCl of 10–20 mL/min indicating severe renal failure, and usually the need for dialysis. The National Kidney Disease Education Program (NKDEP) recommends using an estimation of GFR (eGFR) from serum creatinine in adults (>18 yr) with chronic kidney disease (CKD) and those at risk for CKD (diabetes, hypertension, and family history of kidney failure).

**METHODS**

1. Formal 24-hr Urinary Collection for Creatinine Clearance

Order a concurrent serum creatinine (SCr) and a 24-hr urine creatinine. A shorter time interval can be used (e.g., 12 hr), but the formula must be corrected for this change; a 24-hr sample is less prone to collection errors.

- **Creatinine x total urine volume**

**Example:** The following are calculations of (a) CrCl from a 24-hr urine sample with a volume of 1,000 mL, (b) a urine creatinine of 108 mg/100 mL, and (c) a Scr of 1 mg/100 mL (1 mg/dL), where time = 1.440 min for 24-hr collection is used.

- **Clearance (CrCl):**
  - **CrCl = 125 mL/min** (1 mL/dL) = 75 mL/min

To determine if there is a valid, full 24-hr collection, the sample should contain 18–25 mg/kg/h of creatinine for adult males or 12–20 mg/kg/h for adult females. If the patient is an adult (110 lb = body surface area of 1.73 m2), adjustment of the clearance for body size is not routinely done. Adjustment for the pediatric patients is a necessity. If the values in the previous example were for a 12-hr-old boy who weighed 70 lb (1.1 m2), the clearance would be:

- **CrCl = 75 mL/min (1.1 m2) = 71 mL/min

2. **Estimated Creatinine Clearance (eGFR)**

- **Estimated glomerular filtration rate (eGFR):** Based on Scr combined with other factors such as age, sex, and race and has generally replaced 24-hr urinary creatinine determinations. Online calculators for adults and children can be found at: http://clinical.niddk.nih.gov/lab-evaluation/calculators.html. (Accessed April 19, 2014)

IV. 24-HR URINE STUDIES

**Cysteamine urine.** See also Section II Hypercalciuria (Absorbptive, Nrenal and Receptive) and Metabolic Stone Evaluation (24-hr urine studies) — Normally ordered as part of a urinalysis metabolic evaluation:
- Normal: Calculi-free diet: 150 mg 24-hr (3.7 mmol/L), average calcium diet: (600–800 mg)/24-hr (2.5–6.2 mmol/L).
- Increased: Hyperparathyroidism, hyperparathyroid, hyperparathyroid tumor, and achondroplasia. Normal: 10–55 mg/24-hr (600–800 mg/24-hr).

**Creatinine, fractionated.** (Nonprotein, secondary, and-disposable):
- Used to evaluate creatinine and paraproteinemia. Avoids drugs that can interfere with the test, leading to false high creatinine values. Totropic steroids, diuretics, calcium, acetaminophen, aspirin, warfarin, alcohol, and aspirin. All these drugs should be discontinued 2 wk prior to testing.
- Normal: Values are variable and dependent on the assay method used. Nonprotein 15–80 mg/24-hr (86–478 mmol/24-hr), protein 0–25 mg/24-hr (0–5.0 mmol/24-hr), uric acid 65–400 mg/24-hr (3.5–20 mmol/24-hr).
- Increased: Phenylketonuria levels are = twice the upper normal value, paraproteinemia, epinephrine administration. Presence of drug (see above).

**Cortisol, free.** — Used to evaluate adrenal cortical function; screening test of choice for Cushing syndrome:
- Normal: 10–55 μg/d (27–150 nmol/L).
- Increased: Cushing syndrome (adrenal hyperplasia from a primary tumor secreting ACTH or ectopic secretion of ACTH by other tumors such as bronchial carcinoma or adrenal tumor secreting cortisol), stress during collection, pregnancy.

- **Cyclophosphamide:**
  - Used to treat proteinuria, microscopic: Normal: 30–45 mg/24-hr (0.6–0.9 mmol/L).
  - Increased: Cyclophosphamide (60 mg/24-hr (1.7 mmol/L)); cyclophosphamide and vincristine syndrome. Up to 250 mg/24-hr (1 mmol/L).

- **Electrophoresis, protein (24-hr urine protein, 24-hr urine globulins):** — Used to evaluate overall serum function; screen for myeloma, monoclonal gammopathy, lymphoma, amyloidosis; can differentiate types of proteinuria (see table below).

**Pattern Description (Type of Proteinuria)**

**Electrophoretic Zones**

- **5-Hydroxyindoleacetic acid (5-HIAA).**
  - Used in diagnosing carcinoid syndrome.
  - Normal: 10–60 μg (10.4–61.6 mmol)/24-hr urine collection.
  - Increased: Carcinoid tumors (except rectal), may or may not be present; other tumors: kidney, breast, bladder, ovary, stomach, testes, pancreas.

**Heavy metals:

- **Lead:** Measures urinary lead concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
- **Mercury:** Measures urinary mercury concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
- **Cadmium:** Measures urinary cadmium concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
- **Copper:** Measures urinary copper concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.

**Urinary nitrogen, urine (urine nitrogen, nitrogen balance, blood-urea nitrogen, BUN):**

- Measures urinary nitrogen concentration.
  - Normal: 15–20 mg/24-hr (28–69 mmol/L); increased: 20–50 mg/24-hr; note: Low values in prepubertal children.
  - Increased: Adrenal cortex abnormalities (renal adenoma, adrenal carcinoma, Cushing syndrome).

**Urea nitrogen, urine (urine nitrogen, nitrogen balance, blood-urea nitrogen, BUN):**

- Measures urea nitrogen concentration.
  - Normal: 12,000–20,000 mg/24-hr (31–52 mmol/L); note: Low values in prepubertal children.
  - Increased: Adrenal cortex abnormalities (renal adenoma, adrenal carcinoma, Cushing syndrome).

**Urea nitrogen, urine (urine nitrogen, nitrogen balance, blood-urea nitrogen, BUN):**

- Measures urinary nitrite concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
  - Decreased: Decreased pyridoxal phosphate, Addison disease.

**Vitamin D deficiency:**

- Measures vitamin D deficiency. Normal: 20 mg/24-hr (7.1 mmol/L) in adults, 10 mg/24-hr (3.4 mmol/L) in children.

**Vitamine D deficiency:**

- Measures vitamin D deficiency. Normal: 20 mg/24-hr (7.1 mmol/L) in adults, 10 mg/24-hr (3.4 mmol/L) in children.

**Electrophoretic Zones**

- **5-Hydroxy-indole-acetic acid (5-HIAA):**
  - Used in diagnosing carcinoid syndrome.
  - Normal: 10–60 μg (10.4–61.6 mmol)/24-hr urine collection.
  - Increased: Carcinoid tumors (except rectal), may or may not be present; other tumors: kidney, breast, bladder, ovary, stomach, testes, pancreas.

- **Heavy metals:**
  - **Lead:** Measures urinary lead concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
  - **Mercury:** Measures urinary mercury concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
  - **Cadmium:** Measures urinary cadmium concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
  - **Copper:** Measures urinary copper concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.

- **Urinary nitrogen, urine (urine nitrogen, nitrogen balance, blood-urea nitrogen, BUN):**
  - Measures urinary nitrogen concentration.
    - Normal: 15–20 mg/24-hr (28–69 mmol/L); increased: 20–50 mg/24-hr; note: Low values in prepubertal children.
    - Increased: Adrenal cortex abnormalities (renal adenoma, adrenal carcinoma, Cushing syndrome).

- **Urea nitrogen, urine (urine nitrogen, nitrogen balance, blood-urea nitrogen, BUN):**
  - Measures urea nitrogen concentration.
    - Normal: 12,000–20,000 mg/24-hr (31–52 mmol/L); note: Low values in prepubertal children.
    - Increased: Adrenal cortex abnormalities (renal adenoma, adrenal carcinoma, Cushing syndrome).

- **Urea nitrogen, urine (urine nitrogen, nitrogen balance, blood-urea nitrogen, BUN):**
  - Measures urinary nitrite concentration. Normal: 100–100 mg/24-hr (1.6–4.0 mmol/L); increased: Exposure.
    - Decreased: Decreased pyridoxal phosphate, Addison disease.

- **Vitamine D deficiency:**
  - Measures vitamin D deficiency. Normal: 20 mg/24-hr (7.1 mmol/L) in adults, 10 mg/24-hr (3.4 mmol/L) in children.

SECTION V

Alternative and Complementary Urologic Therapies

Section Editors: Franklin Lowe, MD, MPH
Sven Wenske, MD
Introduction

National Center for Complementary and Alternative Medicine (NCCAM), a division of the National Institutes of Health (NIH), conducts and supports research and provides information about complementary health. In a recent national survey, 38% of adults used some form of complementary and alternative medicine (1). “Complementary medicine” refers to use of Complementary and Alternative Medicine (CAM) together with conventional medicine, such as using acupuncture in addition to usual care to help lessen pain. Most use of CAM by Americans is complementary. “Alternative medicine” refers to use of CAM in place of conventional medicine. “Integrative medicine” combines treatments from conventional medicine and CAM for which there is some high-quality evidence of safety and effectiveness. It is also called integrated medicine.

CAM practices are often grouped into broad categories, such as natural products, mind and body medicine, and manipulative and body-based practices. Although these categories are not formally defined, they are useful for discussing CAM practices and some CAM practices may fit into more than 1 category. This chapter provides an overview of some of the CAM practices that are used or are related to the practice of urology.

Mind and Body Medicine

Mind and body practices focus on the interactions among the brain, mind, body, and behavior, with the intent to use the mind to affect physical functioning and promote health. Many CAM practices embody this concept in different ways. Meditation techniques, yoga, and acupuncture are some of these techniques.

Acupuncture, the application of solid needles inserted into defined spots in the skin, has been described thousands of years ago as part of ancient Chinese medicine. Although its main application has been to treat a variety of chronic conditions, such as back pain, obesity, addictions, and many others, more recently acupuncture has found its way into modern medicine and is now also part of daily clinical routine in many urologic practices. Especially urologic diseases that are difficult to treat, such as premature ejaculation, lower urinary tract symptoms (LUTS) and overactive bladder (OAB), chronic prostatitis/chronic pelvic pain syndrome (CPPS), or side effects (eg, hot flashes) of androgen-deprivation therapy (ADT) for advanced/metastatic prostate cancer, are the primary targets of acupuncture in urology (2).

Results from a clinical study in patients with LUTS or CPPS, 1 of the most difficult to treat urologic conditions, or patients with increased urinary frequency and urgency after radical prostatectomy, showed good results of acupuncture in decreasing symptoms and improving quality of life (3). Good success has also been reported in studies on patients that receive acupuncture for hot flashes, 1 of the most common side effects of ADT. A randomized placebo-controlled study showed recently the effects of acupuncture in the treatment of premature ejaculation in comparison to placebo and the standard treatment using paroxetine (4). Whereas paroxetine reduced the validated Premature Ejaculation Diagnostic Tool (PEDT) score from 17 to 10.5, acupuncture achieved a reduction from 16 to 11, which was significantly better than placebo. Usually, treatments are being applied twice per week for the 1st 6 wk. If patients respond to the treatment and if symptoms improve, the treatment frequency is reduced to once per week, and continues for a total of 12 wk. After that, a maintenance treatment schedule may be needed to prevent recurrent or increasing symptoms.

While the mechanisms of acupuncture are still not entirely understood, the main hypothesis is that certain neurotransmitters (eg, serotonin, endorphins) are being released under needle stimulation, and that there exists an alternative connective tissue communication system unrelated to the peripheral and central nervous systems.

In addition to acupuncture, also pelvic floor muscle training (PFMT), relaxation, and yoga have all been shown to decrease muscle contractions and stress of the pelvic floor. One analysis from Stanford University studied the treatment of intra- and extrapelvic myofascial trigger point release therapy, and training in paradoxical relaxation including cognitive behavioral methods in patients with CPPS, with good results (5).

Overall, especially after exhausting standard treatments for common benign urologic disorders, acupuncture and other complementary therapy offer good alternative treatment approaches with limited potential for adverse events.

Manipulative and Body-Based Practices

Manipulative and body-based practices focus primarily on the structures and systems of the body, including the bones and joints, soft tissues, and circulatory and lymphatic systems. 2 commonly used therapies fall within this category: Spinal manipulation and massage therapy. Limited data is available but the literature suggests that 2 methods of manual therapy (myofascial physical therapy and global therapeutic massage) may benefit patients with urologic CPPS (6).
ACTIVE HEXOSE CORRELATED COMPOUND (AHCC)
AHCC is derived from the mycelia (branches) of the mushroom Lentinula edodes, and contains beta-glucans, a component that is known for its antiviral properties. It is used in the treatment of chronic immune conditions.

CAROTENOID POWDER SUPPLEMENT (Vaccinium macrocarpon)
Carotene powder is derived from cranberry extract and is used in the treatment of prostatitis.

CAUSAL SPECIES (Capsicum annuum)
Capsicum annuum is a species of the Capsicum genus and is used in the treatment of pain and inflammation.

COMMON NATURAL PRODUCTS USED IN UROLOGY
Several natural products are used in the treatment of urological conditions, including cranberry juice, saw palmetto, and pygeum.

CUTEBITUM (Luteolin subalpino)
Cutebitum is a natural supplement derived from the plant Luteolin subalpino and is used in the treatment of urological conditions.

GINKGO BILoba
Ginkgo biloba is derived from the seed of the Ginkgo biloba tree and is used in the treatment of a variety of conditions, including cognitive impairment and cardiovascular disease.

HOLISTIC PRODUCTS AND HERBS
A variety of holistic products and herbs are used in the treatment of urological conditions, including cranberry, saw palmetto, and pygeum.

L-BENEFIC (Polyphenol extract)
L-Benific is a product derived from the leaves of the plant L. officinalis and is used in the treatment of urological conditions.

LUTETIA (Luteolin officinate)
Lutetia is a natural supplement derived from the plant L. officinate and is used in the treatment of urological conditions.

MASTODON (Radix urticae)
Mastodon is a natural supplement derived from the root of the plant Urtica dioica and is used in the treatment of urological conditions.

MELATONIN (Melatonin)
Melatonin is a hormone derived from the pineal gland and is used in the treatment of urological conditions.

POLYVINYL (Polyvinyl alcohol)
Polyvinyl is a synthetic polymer used in the treatment of urological conditions.

PROSTATE SUPPORT (Pygeum africanum)
Pygeum africanum is a natural supplement derived from the bark of the African plum tree and is used in the treatment of prostate conditions.

QUINOSIL (Quinone silicate)
Quinonisol is a natural supplement derived from the plant Quinone silicate and is used in the treatment of urological conditions.

SMALLRICE (Spermatozoon)
Smallrice is a natural supplement derived from the sperm of the plant Spermatozoon and is used in the treatment of urological conditions.

SPIDER CRANBERRY (Vaccinium macrocarpon)
Spider cranberry is derived from the berry of the plant V. macrocarpon and is used in the treatment of urological conditions.

SUPPLEMENTS (Vaccinium macrocarpon)
Supplements derived from the cranberry are used in the treatment of urological conditions.

TURMERIC (Curcumin)
Turmeric is a natural supplement derived from the plant Curcuma longa and is used in the treatment of urological conditions.

VITAMIN D (Calciferol)
Vitamin D is a nutrient derived from the food we eat and is used in the treatment of urological conditions.

WATERFORD (Aquatic plant)
Waterford is a natural supplement derived from the aquatic plant Waterford and is used in the treatment of urological conditions.
Overall, the protective effect of lycopene is unclear, as studies have found it to have potential anticancer effects against damage from free radicals. In several pigment acts basically as an antioxidant, protecting cells against damage from free radicals. Lycopene is a major carotenoid component of tomato, which has been reported to cause tachyarrhythmias. Phytoestrogens of the prenyl-flavone family. It has estrogenic due to the presence of novel potent (27,28). However, extracts of epimedium are strongly antihypertensive and antiandrogenic, and antiestrogenic effects (38). It has almost no effect upon prostate size and no effect upon PSA levels (39). There are no known significant health risks or adverse effects.

POMEGRANATE (Punica granatum)

Pomegranate juice is known for its high vitamin C content, as well as vitamin B6 (pyridoxine), potassium, and natural phenols, such as ellagitannins and flavonoids with extremely effective free radical-scavenging properties. Increasing evidence shows that pomegranate juice has potential to inhibit growth and induce the invasion of prostate cancer cells both in vitro and in vivo. A phase II clinical trial, in which patients with rising PSA after primary treatment with curative intent of prostate cancer were given 8 oz of pomegranate juice per day, showed that the mean PSA doubling time increased significantly in men under treatment with pomegranate juice from 15 to 54 mo (p < 0.001) (40). One of the hypothesized mechanisms in which pomegranate juice affects many of the cellular processes involved in cell death and also affects signaling pathways that could inhibit cell migration and invasion (41).

PUMPKIN SEED (Cucurbita pepo)

Fresh and dried seeds are taken whole or ground for the treatment of BPH or OAB. Active compounds are thought to be phytosterols (42,43). There are no recent clinical trials and therefore no evidence establishing its efficacy. There are no known side effects.

RESVERATROL

Resveratrol is a potent antioxidant found in wine, especially in high concentration in Pino Noir, but also in grapes and berries. Research has demonstrated that it inhibits cancer growth through reduction of cell proliferation and metastasis, and reduction of cell apoptosis. On a molecular level, it has been shown that mechanisms involved are Inhibition of Akt and suppression of KRAS 1 oncogene expression (44). These antitumor effects of resveratrol were observed in in vitro and in vivo preclinical studies with the common prostate cancer cell lines PC3, DU145, and LNCaP.
A pollen extract obtained by microbial digestion and extraction by water and organic solvents. Cernilton is the branded product. Active ingredients are thought to be β-sitosterols (45). It is used for the treatment of BPH and prostatitis and CPPS (46). In vitro inhibition of synthesis of prostaglandin and estradiol metabolites has been demonstrated (47). No long-term conclusive clinical studies exist. Side effects are reportedly minimal.

**SAW PALMETTO BERRY** *(Serenoa repens, Sabal verruculata)*

There are many different extraction processes and therefore many different brands of saw palmetto. The composition of these brands is variable. A recent NIH-sponsored double-blind, placebo-controlled study using the Indra brand showed no statistical difference between placebo and saw palmetto berry treatment for BPH/LUTS. Proenase brand is the most widely studied product (see “Premenopausal” above). Minimal side effects are associated with saw palmetto. Saw palmetto berry extract (SBPE) compounds are also sold as “prostate health.” SBPE includes ingredients such as β-sitosterol and stigmasterol with no reliable clinical data to support their use. A recent large meta-analysis documented no significant clinical benefit of Saw palmetto on LUTS or prostate volume (10). Saw palmetto extract does not affect serum prostate-specific antigen more than placebo, even at relatively high-dose (48). In addition it appears safe with the saw palmetto extract used in the CAMUS trial showed no evidence of toxicity at doses up to 3 times the usual clinical dose during an 18-mo period.

**SELENIUM**

A trace mineral that may prevent the development of prostate cancer. Epidemiologic studies suggest a chemopreventive effect (49). A study of patients with high-grade PIN suggested that selenium reduced the incidence of prostate cancer on subsequent biopsy. The National Cancer Institute-sponsored SELECT trial was a 10 yr prospective trial that began in 2001 of over 35,000 men studying the prostate cancer chemopreventive effects of selenium and vitamin E alone and in combination (49). The data monitoring safety board (DMSB) halted the trial in the fall of 2006. Their concerns were that the supplements did not appear to offer any benefit. Although there was a statistically nonsignificant trend to increasing prostate cancer with vitamin E alone and increased diabetes risk in men on selenium alone.

**SOUTH AFRICAN STAR GRASS** *(Hypoxis rooperi)*

This extract is taken for BPH/LUTS. The active compound is thought to be β-sitosterols, which are thought to induce apoptosis by transforming growth factor (TGF) signaling (46). Initial studies showed dramatic improvements in symptom scores and flow rates; however, confirmatory studies are still needed (51). Adverse effects are believed to be minimal.

**STINGING NETTLE** *(Urtica dioica, Urtica radix)*

Razors is a branded form of this extract; (see Razors section above). The clinical evidence of the effectiveness of nettle root is based primarily on open studies, and the significance of this must be confirmed (14, 52). Minimal toxicity is associated with stinging nettle use.

**VITAMIN D3 (Cholecalciferol)**

As a fat-soluble vitamin, vitamin D3 plays a key role in overall health, as it mainly maintains calcium and phosphate homeostasis. However, it has also been shown to exhibit antineoplastic effects on various types of cancer such as colon, breast, and prostate cancer (53). The Institute of Medicine (IOM) has reviewed and updated the dietary reference intakes (DRIs) for vitamin D. It found that there is strong evidence to support the use of vitamin D with calcium for bone health, but it was lacking for other health conditions. Dosages for patient with various health issues differ. The recommended daily allowance (RDA), as set in 2011, is based on age, as follows: For those 1–70 yr of age, 600 IU daily, for those 71 yr and older, 800 to daily, and for pregnant and lactating women, 1,200 to daily. The IOM further recommended that serum 25(OH)D levels of 20 ng/mL (50 nmol/L) is adequate, and levels ≥ 50 ng/mL (125 nmol/L) could have potential adverse effects. However, dosages for unselected patients may differ based on underlying health disorders and concomitant medications (underlying osteopenia, ADT, therapy with bisphosphonates in patients with metastatic prostate cancer, etc.)

**VITAMIN E (α-Tocopherol)**

Vitamin E, another fat-soluble essential vitamin, was initially thought to prevent prostate cancer (80). However, the National Cancer Institute–sponsored SELECT trial, studying prostate cancer chemopreventive effects of selenium and vitamin E alone and in combination (50). The follow-up publication in 2011 even reported a significantly increased prostate cancer risk in healthy men with dietary supplementation with vitamin E (51). In addition, vitamin E supplementation above dosages of 400 IU per day was found to significantly increase risks of cardiovascular events.

**YOHBININE (Paussinystalla yohimbe) YOCON, YOHIMEX**

An extract of the bark of the yohimbe tree has been used for erectile dysfunction and decreased libido. The mechanism of action is an α2-adrenergic agonist. Conflicting studies show both positive and no effect when compared to placebo (52). It appears to have greatest utility for men with psychogenic impotence. Despite the advent of phosphodiesterase 5 (PDE5) inhibitors, there is widespread utilization of this over-the-counter product. Side effects include anxiety, tremors, diziness, hypertension, and tachycardia. Do not use with antidepressants (eg, MAOIs or similar agents).

**ZYFLAMEND**

A formula containing 10 different herbs, is a dietary supplement marketed for the support of cardiovascular and joint function and healthy inflammation response. It is thought to have anti-inflammatory, antiproliferative, and antiangiogenic properties. Several in vitro studies have shown that Zyflamend decreases COX-1 and COX-2 enzymatic activity, induces apoptosis, and reduces angiogenesis receptor expression in NCI/CA1 cells (57). Moreover, it was found to inhibit angiogenic acid pathways in human prostate cancer PZC cells. Moreover, it also inhibits the proliferation of oral squamous carcinoma, pancreatic cancer, and melanoma cells in vitro. In an animal model, it inhibited the growth of both hormone-naïve and castrate-resistant prostate cancer, and reduced the expression of PSA. However, the latter could not be shown in a phase I clinical trial in men with PIN at Columbia University Medical Center, where Zyflamend was well tolerated, but did not lead to any significant changes in serum PSA levels (58).

SECTION VI

Urologic Drug Reference

Section Editors: T. Ernesto Figueroa, MD, FAAP, FACS
Leonard G. Gomella, MD, FACS
Kevin R. Loughlin, MD, MBA, FACS
Jack H. Mydlo, MD
This section is designed to be a quick reference of medications commonly used in urology or of those that have significant impact on the GU system. Although some general information about the drug may be presented, this is not intended to be a complete authoritative listing for each medication; the focus here is on the practice of urology. You should be familiar with all the indications, contraindications, adverse effects, and drug interactions of any medication that you prescribe. Such detailed information is beyond the scope of this book but can be found in the manufacturer’s package insert, product websites, in the Physicians’ Desk Reference (PDR), or from the American Hospital Formulary Service.

Medications are listed by generic name, with some of the more common trade names noted. Common uses and urology-specific uses are listed in addition to the official labeled indications (FDA approved), because many available medications are used to treat various conditions based on the medical literature, and these uses are not listed in the package insert. Asterisks are placed before and after the official US FDA approved indications. This additional use information is based on the editorial review of the literature and is representative of urology practice patterns primarily in the US. Where no pediatric dosage is provided, the implication is that the use of the agent is not well established in this age group. Controlled substances are indicated by the symbol [C]. Increasingly, drug interaction and medication side effects can be related to a drug’s metabolism and the enzymes of the cytochrome P450 system are essential for the metabolism of many medications. There are more than 50 CYP450 enzymes, but the CYP1A2, CYP2C9, CYP2C19, CYP2D6, and CYP3A4 enzymes metabolize 90% of drugs and are predominantly expressed in the liver. The table at the end of the chapter (page 975) summarizes some of the common medications and their CYP450 interactions that are noted for many of the medications listed here.

### MEDICATION KEY

Medications are in alphabetical order by their generic name. Some of the more commonly recognized trade names in the US are listed for each (in parentheses after the generic name). If a drug is available without prescription, it is noted as OTC (over-the-counter).

**GENERIC DRUG NAME (SELECTED COMMON BRAND NAMES) [CONTROLLED SUBSTANCE DESIGNATION] [OTC]**

**WARNING:** Summarized versions of the Black Box precautions deemed necessary by the FDA. These are significant precautions and contraindications concerning the individual medication. **Usual:** This includes both FDA-labeled indications bracketed by **~** and other “off-label” uses of the medication. Because many medications are used to treat various conditions based on the medical literature, and these uses are not listed in their package insert, we list common uses of the medication in addition to official labeled indications (FDA approved) based on input from our editorial board. **Action:** How the drug works. This information is helpful in comparing classes of drugs and understanding side effects and contraindications. **Spectrum:** Specifies activity against selected microbes for antimicrobials. **Dose:** Adults & Peds: When no specific pediatric dose is given, the implication is that this drug is not commonly used or indicated for that age group. At the end of the dosing line, important dosing modifications may be noted (ie, take with food, avoid antacids, etc.). **IP:** (Warning/Precaution): (Pregnancy/fetal risk categories, breast-feeding [as noted below]) Cautions concerning the use of the drug in specific settings. **C:** Contraindications. **Disp:** Common dosing forms. **SE (Side Effects):** Common or significant side effects. **Notes:** Other key useful information about the drug, including additions made by our editorial board.

### CONTROLLED SUBSTANCE CLASSIFICATION

Medications under the control of the US Drug Enforcement Agency (DEA) (Schedules I–V controlled substances) are indicated by the symbol (C). Most medications are uncontrolled and do not require a DEA prescriber number or a special prescription pad. The following is a general description for the schedules of DEA-controlled substances.

**Schedule (C-I):** All nonresearch use forbidden (eg, heroin, etc.).

**Schedule (C-II):** High addictive potential; medical use accepted. No telephone call-in prescriptions; no refills.

**Schedule (C-III):** Low to moderate risk of physical dependence, high risk of psychologic dependence; prescription usually must be rewritten after 6 mo or 5 refills (eg, codeine, oxycodone).

**Schedule (C-IV):** Limited potential for dependence; prescription rules same as for Schedule III (eg, buprenorphine, propoxyphene).

**Schedule (C-V):** Very limited abuse potential; prescribing regulations often same as for uncontrolled medications; some states have additional restrictions.

### FDA FETAL RISK CATEGORIES

**Category A:** Adequate studies in pregnant women have not demonstrated a risk to the fetus in the 1st trimester of pregnancy; there is no evidence of risk in the last 2 trimesters.

**Category B:** Animal studies have not demonstrated a risk to the fetus, but no adequate studies have been done in pregnant women.

**Category C:** Animal studies have shown an adverse effect on the fetus, but no adequate studies have been done in humans. The benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.

**Category D:** Animal studies have shown an adverse effect on the fetus; but adequate studies in pregnant women have not demonstrated a risk to the fetus during the 1st trimester of pregnancy, and there is no evidence of risk in the last 2 trimesters.

**Category X:** Animal studies have shown an adverse effect on the fetus, but no adequate studies have been done in humans. The benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.

</table>
**ACETAMINOPHEN (CODEINE) (TYLENOL NO. 2, 3, AND 4) [C-II, C-V]**

**USES:**
- Mild-mild pain (No. 2–3); moderate pain (No. 4).
- Combined APAP and narcotic analgesic.

**DOSE:**
- Adults: 1–2 tabs q4-h to 30–60 mg/codeine q4–6h based on codeine content (max. dose APAP = 4 g/day). 
- Pediatric: 325–650 mg PO or PR q4–6h or 1,000 mg q6h; max. 4 g/d.

**NOTES:**
- Associated w/ doses 4 g/d; limit SEs (hypokalemia and hypertension); if taken with warfarin; serious skin rxns (SJS, TEN), photosensitivity, hyperglycemia.
- Absorption may be reduced w/ CYP3A4 substrates/CYP3A4 inhibitors or inducers; do not use w/ severe liver insufficiency.

**DISP:**
- Tablets 500 mg.

**ACETYLCYSTEINE (ACETADOTE, MUCOMYST)**

**USES:**
- Mucolytic, antioxidant to acetaminophen hepatotoxicity, adjacent treat chronic bronchopulmonary disease & cystic fibrosis; prevent contrast-induced renal dysfunction.

**ACTIONS:**
- Splits mucoprotein disulfide linkages; reduces glutathione in acetaminophen OD to protect liver.

**DOSE:**
- Adult: PO or IV: 140 mg q4-h, then 70 mg q8-h × 7 days (dose may be limited ≤1.5 mg/kg q6-h for patients ≤65 kg or ≤25 mg/kg q6-h for patients >65 kg).
- Adult: PO or IV: 35 mg/kg q8-h × 7 days (dose may be limited ≤1.5 mg/kg q6-h for patients ≤65 kg or ≤25 mg/kg q6-h for patients >65 kg).

**NOTES:**
- Activated charcoal adsorbs PO
- Sodium bicarbonate may increase availability; use only if severe toxicity.

**ACIDOPHILUS, OMIFRIM IV (Rx), TYLENOL, OTHER GENERIC**

**NOTC**

**W/ Rx:**
- May cause acute liver failure; associated w/ doses > 4,000 mg/d & taking APAP in > 1 product.

**DOBIEF:**
- Mild–mod pain, HA, fever

**ACTIONS:**
- Nonspecific analgesic; CVS synth of prostaglandin & hypotensive & hypothermic effect.

**DOSE:**
- Adults: 125–450 mg PO or PR q4-h to 1,000 mg PO q4–8-h; max. 4 g/d, max. 4 g/d.
- Pediatric: 0.5–8 mg/kg q4–6h; max. 4 g/d.
- Pediatric: < 12 kg: 10–15 mg/kg q4–6h; max. 5 g/d.
- Pediatric: 12–25 kg: 15 mg/kg q4–6h; max. 10 g/d.
- Pediatric: 25–50 kg: 12.5 mg/kg q4–6h max. 7.5 mg/kg q4–6h.

**W/P:**
- [C] + w/ high-dose aspirin and acetazolamide, as readministration. With serious reactions occur, d/c use.

**NOTES:**
- Additive toxicities to sulfonamides (e.g., Stevenson–Johnson syndrome [SJS], toxic epidermal necrolysis [TEN], hepatic necrosis, agranulocytosis, aplastic anemia, and other blood dyscrasias). Sensitizations w/ a sulfonamide is possible, cross-sensitivity may be possible.

**ACETYLCYSTEINE**

**USES:**
- Prevent renal injury risk.

**ACTIONS:**
- Adjunct for chronic urea-splitting UTI infection.

**DOSE:**
- Adult: 325 mg of APAP/325 mg codeineudent until available. FDA advisory has rec’d in max. dose to 3,000 mg/d.

**ACETAMINOPHEN (APAP, N-ACETYL-O-AMINOHEXANOL) (ACEPHEN, OMIFRIM IV [Rx]), TYLENOL, OTHER GENERIC [(OTC)]

**WARNING:**
- May cause acute liver failure; associated w/ doses > 4,000 mg/d & taking APAP in > 1 product.

**DOSE:**
- Adults: 125–450 mg PO or PR q4-h to 1,000 mg PO q4–8-h; max. 4 g/d, max. 4 g/d.
- Pediatric: 0.5–8 mg/kg q4–6h; max. 4 g/d.
- Pediatric: < 12 kg: 10–15 mg/kg q4–6h; max. 5 g/d.
- Pediatric: 12–25 kg: 15 mg/kg q4–6h; max. 10 g/d.
- Pediatric: 25–50 kg: 12.5 mg/kg q4–6h max. 7.5 mg/kg q4–6h.

**W/P:**
- [C] + w/ high-dose aspirin and acetazolamide, as readministration. With serious reactions occur, d/c use.

**NOTES:**
- Additive toxicities to sulfonamides (e.g., Stevenson–Johnson syndrome [SJS], toxic epidermal necrolysis [TEN], hepatic necrosis, agranulocytosis, aplastic anemia, and other blood dyscrasias). Sensitizations w/ a sulfonamide is possible, cross-sensitivity may be possible.

**ACETAMINOPHEN (APAP, N-ACETYL-O-AMINOHEXANOL) (ACEPHEN, OMIFRIM IV [Rx]), TYLENOL, OTHER GENERIC [(OTC)]

**WARNING:**
- May cause acute liver failure; associated w/ doses > 4,000 mg/d & taking APAP in > 1 product.

**DOSE:**
- Adults: 125–450 mg PO or PR q4-h to 1,000 mg PO q4–8-h; max. 4 g/d, max. 4 g/d.
- Pediatric: 0.5–8 mg/kg q4–6h; max. 4 g/d.
- Pediatric: < 12 kg: 10–15 mg/kg q4–6h; max. 5 g/d.
- Pediatric: 12–25 kg: 15 mg/kg q4–6h; max. 10 g/d.
- Pediatric: 25–50 kg: 12.5 mg/kg q4–6h max. 7.5 mg/kg q4–6h.

**W/P:**
- [C] + w/ high-dose aspirin and acetazolamide, as readministration. With serious reactions occur, d/c use.

**NOTES:**
- Additive toxicities to sulfonamides (e.g., Stevenson–Johnson syndrome [SJS], toxic epidermal necrolysis [TEN], hepatic necrosis, agranulocytosis, aplastic anemia, and other blood dyscrasias). Sensitizations w/ a sulfonamide is possible, cross-sensitivity may be possible.
ALDESKLEUKIN (IL-2) (PROLEUKIN)

WARNING: Restrict to pts w/ IL-2 cardiac/pulmonary functions as defined by formal testing. Caution w/ IL-2 cardiac dysfunction. Administer in hospital setting w/ physician experienced w/ antinecotic agents. Aux: w/ capillary leak syndrome (CLS) characterized by ↓ BP and organ perfusion w/ potential for cardiac/respiratory tox, GI bleeding/infection, renal insufficiency, edema, and mental status changes; ↓ risk of sepsis and bacterial endocarditis. Thrush bacterial infection before use. Pts w/ central lines are at ↑ risk for infection. Propofol w/ oxacillin, nafcillin, ciprofloxacin, or vancomycin may reduce staphylococcal infection. Hold w/ moderate-severe lethargy or somnolence; continue use may result in coma.

USES: Met RCC & melanoma.

ACTIONS: Acts via T-2 receptor; many immunomodulatory effects.

DOSE: 6,000 IU/kg q8h = max. 1.4-doses daily 1-5 day and days 15-19 of 28-day cycle (DAYSA schedule for RCC); other schedules (eg, “high dose” schedule for RCC); other schedules (eg, “high dose” schedule for RCC); other schedules (eg, “high dose” schedule for RCC);

ALFUSOZIN (UROXATRAL, GENERIC)

USES: "Symptomatic BH*.

ACTIONS: α-Blockers

DOSE: 10 mg PO daily immediately after the same meal, do not crush/hold.

W/P: [B, C, T] w/ any Hx

BP: ↓, ↓ BP: ≤ 80/60 mmHg, urine output ≤ 0.5 mL/kg body weight/h; ↓ BP: ≤ 80/60 mmHg, urine output ≤ 0.5 mL/kg body weight/h

SE: Headache, syncope, dizziness; rare priapism.

NOTES: Do not cut or crush.

ALLOPURINOL (ALLOPRIM, ZYLOPRIM, GENERIC)

USES: "Gout, hyperuricemia of malignancy, uric acid urolithiasis, recurrent calcium oxalate calcium uric acid urolithiasis, recurrent calcium oxalate calculi (w/ urinary uric acid > 800 mg/dL in males and 700 mg/dL in females).* "

ACTIONS: Xanthine oxidase inhibitor; ↓ uric acid production.

DOSE: Adults: 100–400 mg PO bid; up to 800 mg/d in renal impairment.

W/P: [B, C, T] ≤ 30 mL/min. w/ NSAID

SE: Headache, nausea, vomiting, diarrhea, abdominal pain, drug fever, rash, pruritus, urticaria, urticarial rash, pruritic rashes, urticaria, GI bleed/infarction, renal & mild hematologic tox (w/ transfusion), WBC, eosinophilia, worsening renal function; 80% have desquamative skin rash, fever, hepatic dysfunction, hematologic tox including leukopenia, anemia, thrombocytopenia; 13% have flu-like syndrome (malaise, fever, chills), 3% with fever, chills, rigors, headache, fatigue, weakness, myalgia, arthralgia; 30% have fever, chills, malaise, myalgia, arthralgia, flu-like syndrome.

ALPROSTADIL, INTRACAVERNOUS (CAVERJECT, CAVERJECT IMPULSE, EDEX)

USES: "Erectile dysfunction.* ACTIONS: A form of prostaglandin E1; relaxes smooth muscles, dilates cavernous arteries, 1 LAKURAR a 80% have desquamative skin rash, fever, hepatic dysfunction, hematologic maladoption, penis deformity/erection, men in whom sexual activity inadvisable.

Counsel about priapism, penile fibrosis, & hematoma risks.

ALPROSTADIL, URETHRAL SUPPOSITORY (MUSE)

USES: "Erectile dysfunction.* ACTIONS: A form of prostaglandin E1; urethral absorption, vasodilator, relaxes smooth muscle of corpus cavernosum.

Dose: 125–200 μg PRN to achieve erection (max. 2 systems/24 h) duration 30–60 min.

W/P: [B, C, T] ≤ 30 mL/min. w/ NSAID

SE: Headache, nausea, vomiting, diarrhea, abdominal pain, drug fever, rash, pruritus, urticaria, urticarial rash, pruritic rashes, urticaria, GI bleed/infarction, renal & mild hematologic tox (w/ transfusion), WBC, eosinophilia, worsening renal function; 80% have desquamative skin rash, fever, hepatic dysfunction, hematologic tox including leukopenia, anemia, thrombocytopenia; 13% have flu-like syndrome (malaise, fever, chills), 3% with fever, chills, rigors, headache, fatigue, weakness, myalgia, arthralgia; 30% have fever, chills, malaise, myalgia, arthralgia, flu-like syndrome.

ALVIMOPAN (ENTEREG)

WARNING: for short-term hospital use only (max. 14 days).

USES: "Accelerate the time to upper and lower gastrointestinal recovery following partial or small bowel resection surgery with primary anastomosis.* ACTIONS: (opioid μ) receptor antagonist; selectively binds GI receptors, antagonizes effects of opioids on GI motility/acidity.

Dose: 12 mg 30 min-3 h preop PO, then 12 mg 8h up to 7 days, max. 15 doses.

W/P: [B, C, T] ≤ 30 mL/min. w/ NSAID

SE: Headache, nausea, vomiting, diarrhea, abdominal pain, drug fever, rash, pruritus, urticaria, urticarial rash, pruritic rashes, urticaria, GI bleed/infarction, renal & mild hematologic tox (w/ transfusion), WBC, eosinophilia, worsening renal function; 80% have desquamative skin rash, fever, hepatic dysfunction, hematologic maladoption, penis deformity/erection, men in whom sexual activity inadvisable.

Counsel about priapism, penile fibrosis, & hematoma risks.

NOTES: Do not cut or crush.

NOTES: Do not cut or crush.

NOTES: Do not cut or crush.

NOTES: Do not cut or crush.

NOTES: Do not cut or crush.

NOTES: Do not cut or crush.
AMLODIPINE/VALSARTAN (HA EXFORGE)

**AMLODIPINE (MIDAMOR, GENERIC)**

**USES:** Calcium channel blocker w/ angiotensin II receptor blocker.

**DOSE:**
- Adults: Initial 5 mg PO q day, max 10 mg PO q day.
- BP: 0–125 mg/mL, w/ hepatic impairment.
- W/P: [D, ?]

**ACTIONS:**
- Calcium channel blocker; relaxes smooth muscle, reduces vascular resistance, decreases total peripheral resistance, and decreases myocardial oxygen demand.

**DISP:** Tabs 2.5, 5, 10 mg.

**NOTES:** Take w/o regard to meals.

**ADVERSE EFFECTS:**
- Edema, headache, palpitations, flushing, dizziness.
- Take w/o regard to meals.

**AMLODIPINE/OLMESARTAN (AZOR)**

**USES:**
- Calcium channel blocker w/ angiotensin II receptor blocker.
- **DOSE:**
  - Initial 4.5 mg PO q day, max 10 mg PO q day.
  - **BP:** With [D, ?] w/o regard to meals.
  - **NOTES:** Take w/o regard to meals.

**ACTIONS:**
- Calcium channel blocker; relaxes coronary vascular smooth muscle.

**DOSE:**
- Adults: 2–3 g PO, q 12 h, w/ hepatic impairment.
- W/P: [C, ?]

**DISP:** Tabs 2.5, 5, 10 mg.

**NOTES:** Take w/o regard to meals.

**AMLODIPINE/OLMESARTAN (HA EXFORGE)**

**USES:** Calcium channel blocker w/ angiotensin II receptor blocker.

**DOSE:**
- Adults: Initial 5 mg PO q day, max 10 mg PO q day.
- BP: [D, ?] w/o regard to meals.
- **NOTES:** Take w/o regard to meals.

**ACTIONS:**
- Calcium channel blocker; relaxes coronary vascular smooth muscle.

**DISP:**
- Adults: Initial 4.5 mg PO q day, max 10 mg PO q day.
- **BP:** With [D, ?] w/o regard to meals.
- **NOTES:** Take w/o regard to meals.

**AMLODIPINE (RANOLIN, EXFORGE)**

**USES:**
- Calcium channel blocker.

**DOSE:**
- Adults: Initial 5 mg PO q day, max 10 mg PO q day.
- BP: [D, ?] w/o regard to meals.
- **NOTES:** Take w/o regard to meals.

**ACTIONS:**
- Calcium channel blocker; relaxes coronary vascular smooth muscle.

**DISP:**
- Adults: Initial 4.5 mg PO q day, max 10 mg PO q day.
- **BP:** With [D, ?] w/o regard to meals.
- **NOTES:** Take w/o regard to meals.
AMLODIPINE/VALSARTAN/HCTZ (EXFORGE HCT)

AMLODIPINE/VALSARTAN/HCTZ (EXFORGE HCT)

WARNING: Use of renin-angiotensin agents in PREGNANCY can cause fetal injury and death, so C5 immediately when PREGNANCY detected.

USES: + Hypertension (not initial therapy).

ACTIONS: Calcium channel blocker, angiotensin II receptor blocker, β-blocker diuretic.

SE: Edema, dizziness, headache, fatigue, t. & k laboratory changes, renal impairment, hypotension, syncope, rash.

ACTIONS: β-blocker, angiotensin receptor blocker, diuretic.

DOSE: Adults: 250–500 mg PO q8h or 875 mg q12h, XR 2,000 mg PO q12h.

SE: Anaphylaxis, fever, chills, headache, J, P, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.

AMPHOTERICIN B LIPID COMPLEX (ABELCET)

USES: "Refactory invasive fungal infection in pts resistant to conventional amphotericin B.

DOSE: Adults & Peds: 3–6 mg/m² IV q10–14d.

NOTES: Do not use in-line filter; check LFTs/lytes.

AMPHOTERICIN B LIPOSOMAL (AMBISOME)

USES: "Refactory invasive fungal infection w/ intolerance to conventional amphotericin B/cryptococcal meningitis in HIV, empiric for fungal meningitis, visceral leishmaniasis.

DOSE: Adults & Peds: 3–6 mg/m² IV q10–14d.

NOTES: Do not use in-line filter; check LFTs/lytes.

AMPICILLIN (GENERIC)

USES: "Neutropenia, G.幽门螺杆菌, E. coli, B, & inhibitor (SIB prophylaxis).

DOSE: Adults & Peds: 250–500 mg PO q6–8h or up to 250 mg PO q4h.

SE: Anaphylaxis, fever, chills, headache, J, P, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.

AMPICILLIN (AMOXIL)

USES: "Ear, lower resp, skin, urinary tract infections from susceptible gram(-) bacteria; +/−Lactam antibiotic; a cell wall synth. Spectrum: (gran-) B, & enterococcus (G), S, & enterococcus (G).

DOSE: Adults: 3–4 mg/kg/d; 1 mg/kg/h IV, q6–8h.

SE: Anaphylaxis, fever, chills, headache, J, P, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.

AMLLODIPINE/VALSARTAN/HCTZ (EXFORGE HCT)

USES: "H. pylori endocarditis prophylaxis, + Lactam antibiotic; a cell wall synth. Spectrum: (gran-) B, & enterococcus (G).

DOSE: Adults: 250–500 mg PO q8h or 875 mg q12h, XR 2,000 mg PO q12h.

SE: Anaphylaxis, fever, chills, headache, J, P, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.

AMOXICILLIN/CLOVANILIC ACID (AUGMENTIN, AUGMENTIN ES-600, AUGMENTIN XR)

USES: "Ear, lower resp, skin, urinary tract infections caused by β-lactamase-producing H, influenzae, S, pneumoniae, & E. coli.

DOSE: Adults: 250–500 mg PO q8h or 875 mg q12h, XR 2,000 mg PO q12h.

SE: Anaphylaxis, fever, chills, headache, J, P, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.

AMMONIUM ALUMINIUM SULFATE (ALUM) [OTC]

USES: "Hemorrhagic cystitis when saline bladder irrigation fails.

ACTIONS: Alginates, forms precipitates over bladder surface.

DOSE: Adults/Peds: 1–4 mg col w/ constant NS bladder irrigation 200–250 mL/h.

W/P: [B, ?].

SE: Constipation, nausea, vomiting.

AMPHOTERICIN B (FUNGIZONE)

USES: "Severe, systemic fungal infections; oral & cutaneous candidiasis.

ACTIONS: Binds ergosterol in fungal membrane, alters permeability.

DOSE: Adults: 3–6 mg/kg/d q12h; max. dose 10/320/25 mg.

W/P: [B, enters breast milk].

SE: Anaphylaxis, fever, chills, headache, J, P, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not substitute 250 mg tabs for one 500-mg tab (possible OD of clavulanic acid).

BENZYL BENZilate (AMPHOTEC)

USES: "Abscesses; systemic candidiasis.

ACTIONS: Binds ergosterol in fungal membrane, alters permeability.

DOSE: Children: 3–4 mg/kg/d; 1 mg/kg/h IV, q6–8h.

SE: Anaphylaxis, fever, chills, headache, J, P, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.

BREZOZ (AMPHOREX)

USES: "Parenteral nutrition, drug eluting devices, hyperkalemia.

ACTIONS: Improves hemodynamics, reduces peripheral vascular resistance.

DOSE: Adults: 1,000–2,000 mg or 8–12 or 250–500 mg PO q8h.

SE: Hypotension, nausea, vomiting, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.

BREZOZ (GENERIC)

USES: "Parenteral nutrition, drug eluting devices, hyperkalemia.

ACTIONS: Improves hemodynamics, reduces peripheral vascular resistance.

DOSE: Adults: 1,000–2,000 mg or 8–12 or 250–500 mg PO q8h.

SE: Hypotension, nausea, vomiting, N/V, P, K, <Mg, BP, anemia.

NOTES: Do not use in-line filter; check LFTs/lytes.
AMPICILLIN-SULBACTAM (UNASYN, GENERIC)

**USES:** Gynecologic, intra-abdominal, skin infections, w/ lactamase-producing S. aureus, Enterococci, H. influenzae, P. mirabilis & Bacteroides sp.

**ACTIONS:** β-Lactam antibiotic & β-lactamase inhibitor; Spectrum: gram + & – as amp alone; also in combination, Aminopenicillin, Bacteriostatic.

**DOSE:**

- **Adults:** 1.5–3 g IV or IV gtt.
- **Ped:** 100–400 mg ampicillin/kg (150–300 mg UnasyN gtt)/q6h; ↓ w/ renal insufficiency.

**W/P:** (R, M).

**Disp:** Powder for injection 1 g (ampicillin 577 mg & sulbactam 423 mg).

**Notes:** A 2:1 ratio ampicillin:sulbactam.

**ANIDULAFUNGIN (ERAXIS)

**USES:** Candidiasis, esophageal candidiasis, other Candida infections (peritonitis, intra-abdominal abscesses).

**ACTIONS:** Echinocandin; ↓ cell wall synthesis. Spectrum: C. albicans, C. glabrata, C. parapsilosis, C. krusei.

**DOSE:**

- **Adults:** 200 mg IV × 1, then 150 mg IV daily [T, 4 days after last (±) culture]. 1.1 mg/m² max, Inf rate.
- **Ped:** 3–4 mg/m² 

**W/P:** (R, M)

- **Cl:** Aminocandin hypersens.

**Disp:** Powder 50, 100 mg

**Notes:** ↓ Inf rate to < 1.1 mg/m² in IV injections.

**APIXABAN (ELIQUIS)

**Warning:** Risk of spinal epidural hematoma w/ paralysis & 3° thoracic events w/ DC in all pts, monitor closely.

**Uses:** Prevents CV death in nonvalvular AF.

**ACTIONS:** Factor Xa inhibitor.

**Dose:** 5 mg BD, 2.5 mg w/ the following:

- **Adults:** Warfarin 60 mg q4 (may be 1.5, 2.5 mg w/ strong dual inhibitor of CYP3A4 and P-glycoprotein; if on 2.5 mg do not use w/ strong dual inhibitor of CYP3A4 and P-glycoprotein.

**W/P:** (R, M)

- **Cl:** Do not use w/ prophylactic values.

**Disp:** Tablets 2.5, 5 mg

**Notes:** ↓ Inf apixaban.

**ATENOLOL (TENORMIN, GENERIC)

**Warning:** Avoid abrupt withdrawal (esp. CAO emb, syndromal T2DM, acute HR, TNF inhibitors).

**Uses:** HTN, angina, post-MI.

**ACTIONS:** Selective β-adrenergic receptor blocker.

**Dose:** 50 mg PO up to 50 mg PO/d; ↓ renal impairment.

**W/P:** (M), D, bronchospasm, abrupt DC can exacerbate angina & ↑ HR risk.

- **Cl:** HR, congestive shock, cardiac failure, 2nd/3rd-degree AV block, sino-atrial dysfunction, pulm edema.

**Disp:** Tablets 25, 50, 100 mg

- **S.E:** HR, β, BF, 2nd/3rd-degree AV block, dizziness, fatigue.

**ATENOLOL & CHLORHLIDONE (TENORETIC)

**Uses:** Malignant HTN.

**ACTIONS:** β-Adrenergic blockade w/ diuretic.

**Dose:** 50–100 mg PO based on atenolol, ↓ dose w/ CVD 25–35 ml/min.

**W/P:** (D), β, ↓, DM, bronchospasm.

- **Cl:** See atenolol; anuria, softening, cyanosis.

**Disp:** Atenolol 50 mg/chlorthalidone 25 mg, aminophylline 100 mg/chlorthalidone 25 mg.

- **SE:** HR, BF, 2nd/3rd-degree AV block, dizziness, fatigue, ↓ K⁺, photosensitivity.

**AVANAFIL (STENDRA)

**Uses:** Erectile dysfunction.

**ACTIONS:** Phosphodiesterase type 5 (PDE5) responsible for GMP breakdown; ↑ cGMP activity to relax smooth muscle in 5° flow to corpus cavernosum, onset 30–60 min (delayed 1–1.25 hr with high fat meals).

**Dose:** 25 mg PO as early as 15 min before sex activity, no more than 1–2x/week; ↓ dose 50–200 mg based on effect; do not use w/ strong CYP3A4 inhibitor, use 50 mg w/ mod CYP3A4 inhibitor; w/ or w/o food.

**W/P:** (M)

- **Cl:** Priapism risk. Hypersensitivity w/ BP meds or substantial alcohol; seek immediate attention w/ hearing loss or acute vision loss (may be NAION; w/ substantial alcohol; seek immediate attention w/ hearing loss or acute vision loss (may be NAION).

**Disp:** Tablets 50, 100, 200 mg.

**Notes:** Mean capitol onset w/ sildenafil (15–30 min).

**ATROPINE, BENZODIAZEPIN, HYDROXYCINNAMIC ACID, METHENAMINE, METHYLENE BLUE, PHENYL SALICYLATE (URISED)

**Uses:** Lower urinary tract dysfunction.

**ACTIONS:** Methylamine in acidic urine neutralizes fornicate/methanet (cardiotonic), methylene blue (cardiovascular-acidic) (imidazolacetic), phenyl salicylate (imidazolacetic), hyoscine and atropine (parasympatholytic; ↓ muscle spasm).

**Dose:**

- **Adults:** 2 tablets PO QID.

- **Ped:** 6 yr: Individually.

**W/P:** (R, M)

- **Cl:** Nausea, vomiting; w/ sulfonamides.

**Disp:** Tablets: atropane 0.5 mg, hyoscyamine 0.05 mg, methylamine blue 4.5 mg, phenyl salicylate 18.1 mg.

**S.E:** Rash, dry mouth, flushing, ↑ pulse, diastolic, blurred vision, unreflex diastasis, voiding difficulties.

**Notes:** Take w/ plenty of fluid; can cause crystalluria; see also hyoscine and methenamine listings.

**AVANAFIL (STENDRA)

**Uses:** Erectile dysfunction.

**ACTIONS:** Phosphodiesterase type 5 (PDE5) responsible for GMP breakdown; ↑ cGMP activity to relax smooth muscle in 5° flow to corpus cavernosum, onset 30–60 min (delayed 1–1.25 hr with high fat meals).

**Dose:** (M) only 100 mg PO as early as 15 min before sex activity, no more than 1–2x/week; ↓ dose 50–200 mg based on effect; do not use w/ strong CYP3A4 inhibitor, use 50 mg w/ mod CYP3A4 inhibitor; w/ or w/o food.

**W/P:** (M)

- **Cl:** Priapism risk. Hypersensitivity w/ BP meds or substantial alcohol; seek immediate attention w/ hearing loss or acute vision loss; may be NAION; w/ CYP3A4 inhibitor (eg. ketoconazole; rifampin, erythromycin) ↑ effect; do not use w/ severe retinal/vascular impairment.

- **Cl:** Severe of use if not advised.

**Disp:** Tablets 50, 100, 200 mg.

**Notes:** Mean capitol onset w/ sildenafil (15–30 min).
AZITHROMYCIN (ZITHROMAX)

USES: Community-acquired pneumonia, pharyngitis, otitis media, skin infections; nongonococcal (chlamydial) urethritis, chancroid & pharyngitis, otitis media, skin infections, PID; Treat & prevention of MAC in HIV.

DOSE: Adults: 5 mg PO q2-3d; then 5 mg PO qd; 25 mg/d q1–2wk, target dose 2–3 mg/kg/d.

adiran of use or dose by ½ if usual or strong CYPLA4A inhibitor.

DISP: Tabs 250, 500, 600 mg; 2 Pack (5-dg, 250 mg); Tri Pack (500 mg tabs x 3); susp 2 g; single-dose unit-dose (Zmax) FR susp (2 x 2) susp 100, 200 mg/mL; inj powder 500 mg, 2.5 mL.

SE: GI upset, metallic taste.

AZTREONAM (AZACTAM)

USES: Acute gonorrhea – UTIs, lower resp, intra-abdominal, skin, genitourinary infections & septicemia.

ACTIONS: Monobactam; 1 Cell-wall synth.

DISP: Intramuscular, IM; optimal number of induction instillations and resection; do not administer intravesical forms SQ or IM;

SE: GI upset, metallic taste.

BACITRACIN, NEOMYCIN, & POLYMYXIN B, TOPICAL (BACIGUENT); BACITRACIN & POLYMYXIN B, TOPICAL (NEOSPORIN); BACITRACIN, NEOMYCIN, & POLYMYXIN B, TOPICAL (CORTISPORIN)

USES: Prevent/Treat of minor skin infections.

ACTIONS: Topical antibiotics w/ added components (anti-inflammatory & analgesics).

DOSE: Apply sparingly BID-QD.

SE: Not for deep wounds, punctures, or animal bites.

BASILIXIMAB (SIMULECT)

WARNING: Use only under the supervision of a physician experienced in immunosuppressive therapy in an appropriate facility.

USES: Prevent acute transplant rejection.

AEs: Myelosuppression; malignancies; risk of infections.

DISP: Powder 10, 20 mg.

SE: Edema, J, HTN, Headache, dizziness, fever, pain, infection. GI effects, electrolyte disturbances.

DOSE: Adult & Peds: >35 kg: 20 mg IV 2 hr before transplant, then 20 mg IV 4 days post-transplant.

Peds: >35 kg: 10 mg 2 hr prior to transplant; same dose 4 days post-transplant.

SE: Hypersensitivity to murine proteins.

DISP: mg powder 10, 20 mg.

SE: Edema, J, HTN, Headache, dizziness, fever, pain, infection. GI effects, electrolyte disturbances.

NOTES: A neutrophilic M.

DOSE: Adult: >35 kg: 20 mg IV 2 hr before transplant, then 20 mg IV 4 days post-transplant.

Peds: >35 kg: 10 mg 2 hr prior to transplant; same dose 4 days post-transplant.

SE: Hypersensitivity to murine proteins.

BASILIXIMAB (SIMULECT)

WARNING: May not be effective in immunosuppressed patients.

USES: Myelosuppression; malignancies; risk of infections.

DISP: Powder 10, 20 mg.

SE: GI upset, metallic taste.

BASILIXIMAB (SIMULECT)

WARNING: Myelosuppression; malignancies; risk of infections.

DOSE: Adult: >35 kg: 20 mg IV 2 hr before transplant, then 20 mg IV 4 days post-transplant.

Peds: >35 kg: 10 mg 2 hr prior to transplant; same dose 4 days post-transplant.

SE: Hypersensitivity to murine proteins.

DISP: mg powder 10, 20 mg.

SE: Edema, J, HTN, Headache, dizziness, fever, pain, infection. GI effects, electrolyte disturbances.

NOTES: A neutrophilic M.

DOSE: Adult & Peds: >35 kg: 20 mg IV 2 hr before transplant, then 20 mg IV 4 days post-transplant.

Peds: >35 kg: 10 mg 2 hr prior to transplant; same dose 4 days post-transplant.

SE: Hypersensitivity to murine proteins.

DISP: mg powder 10, 20 mg.

SE: Edema, J, HTN, Headache, dizziness, fever, pain, infection. GI effects, electrolyte disturbances.

NOTES: A neutrophilic M.

DOSE: Adult: >35 kg: 20 mg IV 2 hr before transplant, then 20 mg IV 4 days post-transplant.

Peds: >35 kg: 10 mg 2 hr prior to transplant; same dose 4 days post-transplant.

SE: Hypersensitivity to murine proteins.

DISP: mg powder 10, 20 mg.

SE: Edema, J, HTN, Headache, dizziness, fever, pain, infection. GI effects, electrolyte disturbances.

NOTES: A neutrophilic M.

DOSE: Adult & Peds: >35 kg: 20 mg IV 2 hr before transplant, then 20 mg IV 4 days post-transplant.

Peds: >35 kg: 10 mg 2 hr prior to transplant; same dose 4 days post-transplant.

SE: Hypersensitivity to murine proteins.

DISP: mg powder 10, 20 mg.

NOTES: A neutrophilic M.
BROMOCRIPTINE (PARLODEL)

**USES:** Parkinson’s disease, hyperprolactinemia, acromegaly, pharyngitis.

**DOSE:** Oral: 0.015–0.1 mg/kg PO q6–24h (max. 10 mg/d).

**ACTIONS:** Agonist to striatal dopamine receptors; reduces prolactin secretion. USES: hyperprolactinemia, acromegaly, pituitary tumors.

**SE:** Edema from CHF, hepatic cirrhosis, & renal disease. May induce withdrawal in opioid dependency. NOTE: May induce withdrawal in opioid dependency.

**BUPIVACAINE (MARCAINE, SENSORCANE, GENERIC)

**WARNING:** Avoid 0.75% for OB anesthesia due to reports of cardiac arrest and death.

**USES:** Local or regional anesthesia or analgesia for surgery, dental and oral surgery procedures, diagnostic and therapeutic procedures, and for obstetrical procedures.

**DOSE:** Local anesthetic: 1–3 mg/mL; duration 5–7 hr; max. 300 mg.

**ACTIONS:** Local anesthetic: 1–3 mg/mL; duration 5–7 hr; max. 300 mg.

**SE:** Drowsiness, dizziness, nasal congestion.

**DISP:** Note for withdrawal if opioid dependent.

**BUTABARBITAL, HYDROXYCaine, PHENAZOPyrIDine**

**USES:** Atropine-like, pain & migraine headache.

**ACTIONS:** Opiate agonist-antagonist w/ central analgesic actions.

**DOSE:** Use: Acute pain: 5–40 mg IM or IV or 50–100 units SQ; in renal impairment.

**SE:** Urinary tract pain w/ UTI, procedures, trauma.

**DOSE:** 1 PO OD, pc & fc; w/ antiacid for UTI.

**BUTABARBITAL, HYDROXYCaine, PHENAZOPyrIDine**

**USES:** Atropine-like, pain & migraine headache.

**ACTIONS:** Opiate agonist-antagonist w/ central analgesic actions.

**DOSE:** Use: Acute pain: 5–40 mg IM or IV or 50–100 units SQ; in renal impairment.

**SE:** Urinary tract pain w/ UTI, procedures, trauma.

**DOSE:** 1 PO OD, pc & fc; w/ antiacid for UTI. 2 days max.

**CALCITONIN (FORTICAL, MICALCIN)

**USES:** Hypercalcemic deaths reported; check CBCs, Cl w/ AKI > 1500 calcium; severe hypercalcemia (exsymptomatic, ↓ BP; bronchospasm) may occur, D/C if no response w/ bisphosphonates, sepsis, N/V/diarrhea, shock & sepsis.

**ACTIONS:** Microtuble inhibitor.

**DOSE:** 25 mg/m² at 1 hr; duration 5–7 hr; may titrate w/ bisphosphonates, sepsis, N/V/diarrhea, shock & sepsis.

**SE:** N/V/diarrhea, renal function deterioration.

**CALCITONIN (FORTICAL, MICALCIN)

**USES:** Hypercalcemic deaths reported; check CBCs, Cl w/ AKI > 1500 calcium; severe hypercalcemia (exsymptomatic, ↓ BP; bronchospasm) may occur, D/C if no response w/ bisphosphonates, sepsis, N/V/diarrhea, shock & sepsis.

**ACTIONS:** Microtuble inhibitor.

**DOSE:** 25 mg/m² at 1 hr; duration 5–7 hr; may titrate w/ bisphosphonates, sepsis, N/V/diarrhea, shock & sepsis.

**SE:** N/V/diarrhea, renal function deterioration.

**CALCITONIN (FORTICAL, MICALCIN)

**USES:** Hypercalcemic deaths reported; check CBCs, Cl w/ AKI > 1500 calcium; severe hypercalcemia (exsymptomatic, ↓ BP; bronchospasm) may occur, D/C if no response w/ bisphosphonates, sepsis, N/V/diarrhea, shock & sepsis.

**ACTIONS:** Microtuble inhibitor.

**DOSE:** 25 mg/m² at 1 hr; duration 5–7 hr; may titrate w/ bisphosphonates, sepsis, N/V/diarrhea, shock & sepsis.

**SE:** N/V/diarrhea, renal function deterioration.
CALCITROL (ROCALCITROL, CALCICUE)

USES: Probable decrease of FPTH levels to treat bone disease. Ca2+ on dialysis.

ACTIONS: 1,25-Dihydroxycholecalciferol (vit D analog); Ca2+ and phosphorus absorption; Ca bone mineralization.

DOSE: Adults: Initial, 0.25 μg PO, 0.25 μg q=4 wk PRN; 0.5–4 g diet to control serum phosphate discomfort. Nonaluminum phosphate binders and low phosphate tox.

DISP: Chew tabs 350, 420, 500, 550, 750, 850 mg; CI: [C, ?].

W/P: [C, ?].

SE: Can vary; ± GI distress.

CI: [B, M].

W/P: [C, ?].

OTHERS) (CALCICUE, CALCIJEX)

USES: Calcium carbonate (Tums, Alka-Mints) [OTC]

USES: NEPHRO-ASSOCIATED HYPERPARATHYROIDISM (HPT) * ACTIONS: Ca2+ spike in serum to PTH absorption.

DOSE: 2–4 tabs PO w/ meals; usual 2,001–2,668 mg PO w/ meals.

W/P: [C, ?].

SE: ↑ GI, possible w/ antacids.

CI: ↑ Ca2+; ↓ GI toxic.

DISP: Hx: ↑ GI, renal calculi.

SE: ↑ Ca2+; ↓ GI toxic.

W/P: [C, ?].

CALCIUM CARBONATE TUMS, ALKA-MINTS [OTC]

USES: Hypochlorhydric-associated gastrointestinal disorders, infant formula, etc. – calcium supplementation.

ACTIONS: Neutrophil granulocytes.

DOSE: 500 mg–2 PO PRN; [G, 70 mg, ]; w/ renal impairment.

W/P: [C, ?].

CI: Hx: ↑ Ca2+; renal calculi, suspected digoxin tox.

DISP: Chew tabs 330, 420, 500, 550, 750, 850 mg; susp.

SE: ↑ Ca2+; ↓ PO 60%, constipation.

W/P: [C, ?].

CULCIONATE (CALCIONATE) [OTC]

USES: Treat & prevent calcium deficiency. 

ACTIONS: Calcium supplement.

DOSE: Adults: 1,000–2,000 mg/d – doses.

Peds: 200–1,300 mg/d.

W/P: [C, ?].

DISP: PO susp 1.8–9.5 g elemental Ca 110–220 mL.

SE: ↑ Ca2+, ↓ PO 60%, constipation.

SE: ↑ PO, ↓ Ca2+.

W/P: [C, ?].

CALCIMET (CALCIUM SALTS) [PHOSPHATE, GLUCONATE, GLUCOPATE]

USES: Calcium replacement, VF, calcium blocker tox (calcium channel block,); severe ↑ hypomagnesemia tetany, hyperparathyroidism in ESRD.

ACTIONS: Calcium supplement replacement.

DOSE: Adults: Replacement: 1–2 g PO. Tetany: 1 g CaO over 10–30 min; repeat in 6 hr PRN.

Hypercalcemia/hyperphosphatemia/calcium channel blocker overdose: 500–1,000 mg (5–10 min of 10% calcium IV); repeat PRN; comparable dose of 10% calcium gluconate 15–30 ml.

Peds: Tetany: 10 mg/kg CaO (5–10 min); repeat in 6–8 hr or use Inf (200 mg/kg max). Hypercalcemia/hyperphosphatemia/calcium channel blocker overdose: Calcium chloride or gluconate 20 mg/kg (11.2 mg/kg slow IV); repeat PRN; renal venous stasis preferred.

Adults & Peds: ↓ calcium oral chelated blood tox in; 0.45 mlg Ca100 mL chelated blood tox (in renal impairment).

W/P: [C, ?].

CI: ↑ Ca2+, suspected digoxin tox.

DISP: SPC: CaH10 10% = 100 mg/ml Ca 27.2 mgmL; CaH10 10% = 100 mg/ml Ca, 28.5 mg/cc; 735 mg Ca; 975 mg Ca; 1 g = 95 mg Ca; Ca glucopate 200 ml = 1 mg/ml; 10% CaO IV; repeat PRN; calcium gluconate 13–30 mL.

Peds: Tetany: 10 mg/kg CaO (5–10 min); repeat in 6–8 hr or use Inf (200 mg/kg max).

Hypercalcemia/hyperphosphatemia/calcium channel blocker overdose: Calcium chloride or gluconate 20 mg/kg (11.2 mg/kg slow IV); repeat PRN; renal venous stasis preferred.

Adults & Peds: ↓ calcium oral chelated blood tox in; 0.45 mlg Ca100 mL chelated blood tox (in renal impairment).

W/P: [C, ?].

CI: ↑ Ca2+, suspected digoxin tox.

DISP: SPC: CaH10 10% = 100 mg/ml Ca 27.2 mgmL; CaH10 10% = 100 mg/ml Ca, 28.5 mg/cc; 735 mg Ca; 975 mg Ca; 1 g = 95 mg Ca; Ca glucopate 200 ml = 1 mg/ml; 10% CaO IV; repeat PRN; calcium gluconate 13–30 mL.

Peds: Tetany: 10 mg/kg CaO (5–10 min); repeat in 6–8 hr or use Inf (200 mg/kg max).

Hypercalcemia/hyperphosphatemia/calcium channel blocker overdose: Calcium chloride or gluconate 20 mg/kg (11.2 mg/kg slow IV); repeat PRN; renal venous stasis preferred.

Adults & Peds: ↓ calcium oral chelated blood tox in; 0.45 mlg Ca100 mL chelated blood tox (in renal impairment).

W/P: [C, ?].

SE: ↑ PO, ↓ Ca2+.

CI: [C, ?].

W/P: [C, ?].

CALCIFEROL (VITAMIN D3, ROCALTROL) [GENERIC]

USES: Treat & prevent vitamin D deficiency.

ACTIONS: Calciferol.

DOSE: Adults: 0.5–4 g diet to control serum phosphate discomfort. Nonaluminum phosphate binders and low phosphate tox.

DISP: Chew tabs 350, 420, 500, 550, 750, 850 mg; susp.

SE: ↑ GI, renal calculi, suspected digoxin tox.

DISP: Chew tabs 330, 420, 500, 550, 750, 850 mg; susp.

SE: ↑ PO, ↓ Ca2+.

W/P: [C, ?].
CEFDROXIL (GENERIC)

USES: *Infections of the nose, skin, bone, & urinary tract.*

ACTIONS: 1st-gen cephalosporin; j cell wall synth. Spectrum: Good gram (+) bacilli & cocci (Streptococcus, Staphylococcus) except Enterococcus); some gram (E. coli, Proteus, Klebsiella).

DOSE: Adults: 1–2 g PO, ↓ doses. Peds: 25–100 mg/kg IV → 6–8 h; ↓ in renal impairment.

W/P: [B, M].

SE: Cephalosporin/PCN allergy.

Disp: Caps 300 mg; susp 250, 375 mg/5 mL.

CI: Cefadroxil/PCN allergy.

W/P: [B, M].

3rd-gen cephalosporin; j cell wall synth. Spectrum: Good gram (+), + (Bacteroides); anaerobic: ↑ (not B. fragilis). Spectrum: S. pneumoniae, S. pyogenes, M. catarrhalis, H. influenzae, some anaerobes (not B. fragilis).

DOSE: Adults: 400 mg PO → daily-BID. Peds: 8 mg/kg PO → daily-BID; ↓ in renal impairment.

W/P: [B, M].

SE: N/V/diarrhea, rash, pruritus, cellulitis, eosinophilia, ↑ LFTs.

Disp: Susp 100, 200, 400 mg/5 mL.

CI: Cefadroxil/PCN allergy.

W/P: [B, M].

4th-gen cephalosporin; j cell wall synth. Spectrum: Most gram (+) - (except Enterococcus); some gram (E. coli, Proteus, Klebsiella). Use with severe infections.

DOSE: Adults: 1–2 g IV q4–8h. Peds: 20 mg/kg q8h for febrile neutropenia; ↓ doses.

W/P: [B, M].

SE: N/V/diarrhea, rash, pruritus, cellulitis, eosinophilia, ↑ LFTs.

Disp: Caps 500 mg; tabs 1 g; susp. 250, 500 mg/mL.

CI: Cefadroxil/PCN allergy.

W/P: [B, M].

50 mg/kg q8h for febrile neutropenia; ↓ doses.

W/P: [B, M].

NOTES: May interfere w/ warfarin.

CEFOTAXIME (CLAFORAN, GENERIC)

USES: *Infections of lower resp tract, skin, bone & joint, urinary tract, meningitis, sepsis, PCP, GC.*

ACTIONS: 3rd-gen cephalosporins; j cell wall synth. Spectrum: Most gram (+) - (except Pseudomonas, some gram (-) cocci S. pneumoniae, S. aureus (penicillinase-resistant pneumococci produced), enterococci [including ampicillin resistant], not Enterobacter; many PCN-resistant pneumococci.

DOSE: Adults: Unconjugated infection: 1 g IVIM q12h; Abdomen sepsis: 1–2 g IVIM q6–8h. Enterococcus: 2 g IVIM q8–12h; G. vini; enterococci, catalase in hemol: 0.5 mg/d PO; ↑; Viocin: G. vini: 1 g/d PO; ↑;

Peds: 50–200 mg/kg/d IV q4–8h; ↓ in renal/hepatic impairment.

W/P: [B, M].

SE: Arthralgia w/ rapid inj; ↑ LFTs.

Disp: Powder for inj 500 mg, 1, 2, 10 g; premixed sol 25 mg/mL, 40 mg/mL.

SE: diarrhea, rash, pruritus, cellulitis, eosinophilia, ↑ transaminases.

CEFOTETAN (GENERIC)

USES: *Infections of the upper & lower resp tract, skin, bone, urinary tract, abdominal & gynecologic system.*

ACTIONS: 2nd-gen cephalosporins; j cell wall synth. Spectrum: Some active against gram (+) anaerobes including B. fragilis, gram (+), including E. coli, Klebsiella, & Proteus.

DOSE: Adults: 1–3 g PO/L/IV. Peds: 20–40 mg/kg/dose IV → q12h (6–12 kg max); ↓ in renal impairment.

W/P: ↓ 1; ↑ 1/2 h; ↑ in renal impairment.

SE: Diarrhea, rash, pruritus, cellulitis, ↑ transaminases, hypoprothrombinemia, & bleeding (1–3 MIT side chain).

NOTES: May interfere w/ warfarin.

CEFOTAXIM (GENERIC)

USES: *Infections of the upper & lower resp tract, skin, bone, urinary tract, Abdominal & gynecologic system.*

ACTIONS: 2nd-gen cephalosporins; j cell wall synth. Spectrum: Good gram (+) - against enteric bacilli (E. coli, Klebsiella, & Proteus), anaerobic & fragilis.

DOSE: Adults: 2–6 g IV q8h. Peds: 80–160 mg/kg/d IV q4–8h (12 kg max); ↓ in renal impairment.

W/P: [B, M].

CI: Cefadroxil/PCN allergy.

Disp: Powder for inj 1, 2, 10 g.

SE: Diarrhea, rash, eosinophilia, ↑ transaminases.
CEFPODOXIME (GENERIC)

USES: "Throat, ear, skin, & urinary tract infections." 

ACTIONS: 3rd-gen cephalosporin; j, cell wall synth. 
Spectrum: β-lactamase–producing H. influenzae, acute uncomplicated N. gonorrhoeae, zone unconfmed gram−. (cf. clavulanate, Proxna) 

DOSE: 
- Adults: 100–400 mg PO q12h. 
- Peds: 10 mg/kg PO – RID; ↓ in renal impairment, w/ food. 

W/P: [R, X]. 

Cl: Cephalosporin/PCN allergy. 

DISP: Caps 250, 500 mg; susp, 125, 250 mg; susp premixed 20, 40 mg/mL. 

CI: Sulfonamide allergy, perioperative CABG. 

W/P: [C/D (3rd tri), ?] w/ renal impairment. 

NOTES: Watch for Sxs of GI bleed; no effect on plt/bleeding time; can affect drugs metabolized by COX-2 pathway. 

CEFIBUTEN (CEDAX)

USES: "Throat, ear, skin, & urinary tract infections, & otitis media."

ACTIONS: 3rd-gen cephalosporin; j, cell wall synth. 
Spectrum: N. influenzae & M. catarrhalis; weak against S. pneumonia. 

DOSE: 
- Adults: 400 mg/d PO. 
- Peds: 9 mg/kg PO, ↓ in renal impairment; take on empty stomach (susp). 

W/P: [R, X]. 

Cl: Cephalosporin/PCN allergy. 

DISP: Caps 400 mg; susp 90 mg/mL. 

CI: Sulfonamide allergy, perioperative CABG. 

NOTES: See "Warning," GI upset, HTN, edema, renal failure, headache. 

CEFTRIAXONE (ROCEPHIN, GENERIC)

WARNING: Avoid in hypothyroidism or confusion w/ calcium-containing products. 

USES: "Throat, ear, skin, bone, abdominal & urinary tract infections, meningitis, septicaemia, GC, PID, perioperative." 

ACTIONS: 3rd-gen cephalosporin; j, cell wall synth. 
Spectrum: fried gram−, excellent β-lactamase producers. 

DOSE: 
- Adults: 1–2 g IM/IV q12–24h. 
- Peds: 50–100 mg/kg IM/IV − q12–24h; decrease dose with renal insuficiency. 

W/P: [R, X]. 

Cl: Proximal acute renal failure (PARF) in children may require dialysis. 

Cl: Cephalosporin allergy, hypothyroidism/neonates. 

DISP: Powder for inj 160 mg, 250 mg IV q8h. 

W/P: [R, X]. 

Cl: Cephalosporin allergy. 

DISP: Caps 50, 100, 200, 400 mg. 

CI: Sulfonamide allergy, perioperative CABG. 

NOTES: See "Warning," GI upset, HTN, edema, renal failure, headache. 

CEFTRIAXONE (CETIN PO, ZINACEF (PARENTERAL), GENERIC)

USES: "Upper & lower resp tract, skin, bone, urinary tract infections, meningitis, & septicaemia." 

ACTIONS: 2nd-gen cephalosporins; j, cell wall synth. 
Spectrum: β-lactamase–producing H. influenzae, acute uncomplicated N. gonorrhoeae, zone unconfmed gram−. (cf. clavulanate, Proxna) 

DOSE: 
- Adults: 250–500 mg PO q6h. 
- Peds: 15–25 mg/kg PO q6h; ↓ in renal impairment; take PO w/ food. 

W/P: [R, X]. 

Cl: Cephalosporin allergy. 

DISP: Caps 250, 500 mg; susp, 125, 250 mg; susp premixed 20, 40 mg/mL. 

CI: Sulfonamide allergy, perioperative CABG. 

NOTES: Cefuroxime film coated tabs & susp not bioequivalent; do not substitute on a mg/mg basis; IV crosses blood–brain barrier. 

CELECOXIB (CELEBREX)

WARNING: ↑ Risk of serious CV thrombotic events, MI, & stroke; can be fatal; ↑ Risk of serious GI adverse events including bleeding, ulceration, & perforation of the stomach or intestine; can be fatal. 

USES: "Osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, acute pain, primary dysmenorrhea." 

ACTIONS: NSAID; decreases urine pH. 

DISP: Caps 200 mg, 400 mg PO q12–24h; decrease dose w/ hepatic impairment. 

CI: Hypersensitivity; anaphylaxis; HTN, edema, renal failure, jaundice. 

NOTES: Watch for Sxs of GI bleed; no effect on pitibinding time; can affect drugs metabolized by P450 pathway. 

CEPHEALXIN (KLEXF, GENERIC)

USES: "Nasal, bone, upper/lower resp tract (streptococcal pharyngitis), otitis media, uncompy synths infections." 

ACTIONS: 1st-gen cephalosporin; j, cell wall synth. 
Spectrum: Streptococcus (including β-hemolytic), Staphylococcus, E. coli, Proteus, & Klebsiella. 

DOSE: 
- Adults & Peds: > 15 yr: 250–1,000 mg PO q8h; < 15 yr: 7–14 days (4 g/d max.). 
- Peds: 30–125 mg/kg PO q8h. 

W/P: [R, X]. 

Cl: Cephalosporin allergy. 

DISP: Caps 250, 500 mg; susp, 125, 250 mg; susp premixed 20, 40 mg/mL. 

CI: Sulfonamide allergy, perioperative CABG. 

NOTES: Cefuroxime film coated tabs & susp not bioequivalent; do not substitute on a mg/mg basis; IV crosses blood–brain barrier. 

CHLOROTHIAZIDE (DIURIL)

USES: "HTN, edema." 

ACTIONS: Thiazide diuretics; decreases urine calcium. 

ACTIONS: 2nd-gen cephalosporins; j, cell wall synth. 
Spectrum: β-lactamase–producing H. influenzae, acute uncomplicated N. gonorrhoeae, zone unconfmed gram−. (cf. clavulanate, Proxna) 

DOSE: 
- Adults: 250–1,5 g IV q8h or 250–500 mg PO bid. 
- Peds: 15–100 mg/kg IV − q8h or 20–30 mg/kg PO − BID; ↓ in renal impairment; take PO w/ food. 

W/P: [R, X]. 

Cl: Cephalosporin allergy. 

DISP: Caps 250, 500 mg; susp, 125, 250 mg; susp premixed 20, 40 mg/mL. 

CI: Sulfonamide allergy, perioperative CABG. 

NOTES: Cefuroxime film coated tabs & susp not bioequivalent; do not substitute on a mg/mg basis; IV crosses blood–brain barrier. 

933
CHLORTHALIDONE (GENERIC)

DOSE:
- Adults: 500–1 mg PO daily; 50–1,200 mg IV (for edema only).
- Peds: ≤ 6 mo: 10–20 mg/kg/d PO ⇒ BID; 4 mg/kg ⇒ daily IV; OK w/ food.
- W/P: (+, +, +).
- Cl: Sensitivity to thiazide/sulfonylureas, anemia.
- DISP: Tabs 250, 500 mg; susp 250 mg/mL IV ⇒ 500 mg/mL
- SE: ↑ K+, Na+, dizziness, hypertension, hyperuricemia, sexual dysfunction; 25–50 mg/d for idiopathic hypercalcemia.
- NOTES: Do not use (M/O) take early in the day to avoid nocturia; use sunblock; monitor lym.

CHLORTHALIDONE (GENERIC)

USES: ↑ HTN, edema.

ACTIONS: Thiazide diuretic.

DOSE:
- Adults: 25–100 mg PO daily.
- Peds: (Not FDA approved) 0.3–2 mg/kg/dose PO ⇒ 1–2 mg/kg/dose IV ⇒ in renal impairment; OK w/ food, NR.
- W/P: (+, +, +).
- Cl: Cross-sensitivity w/ thiazides or sulfonamides; anemia.
- DISP: Tabs 25, 100, 150 mg.
- SE: ↑ K+, dizziness, photosensitivity, ↑ glucose, hyperuricemia, sexual dysfunction; 25–50 mg/d for idiopathic hypercalcemia.

CHOLECALCIFEROL (VITAMIN D3) (DELTA D)

USES: Dietary sup to Tract vitamin D deficiency.

ACTIONS: ↑ Intestinal Ca2+ absorption.

DOSE: 400–1,000 IU PO.

W/P: (D dose above the RDA), + (+).

Cl: ↑ Ca2+, hypercalciuria, allergy.

DISP: Tabs 400, 1,000 IU.

SE: ↑ Ca2+ renal failure, HTN, psychosis.

NOTES: 1 mg cholecalciferol = 40,000 IU ⊥ D activity.

CIPROFLOXACIN (CIPRO, CIPRO XR)

WARNING: ↑ Risk Achilles tendon rupture and tendinopathy. ↑ in risk ⇒ 40–60 y on thiazide or w/ organ transplant; axial w/ myopathy–myalgia, may ↑ muscle weakness.

USES: Treat lower resp tract, urinary, skin & skin structure, bone/joints, complex intra-abdominal infection (peritonitis, typhoid, infectious diarrhea), urticaria GC, inhaled asthma, futures including poscid; Peds only for multi resistant UTI not as first agent.

DOSE: Adults: 250–750 mg PO q2–4h; XR 500–1,000 mg PO q2–4h; 200–400 mg IV q12h; J ⇒ renal impairment.

CITRIC ACID, GLUCONOLACTONE, AND MAGNESIUM CARBONATE (RENACIN)

USES: Chemolysis of calculi: dissolution; insoluble Ca2+ of the urinary tract composed of apatite (calcium phosphate) or struvite (magnesium ammonium phosphate) in nonsurgical candidates; adjunctive therapy to dissolve residual urothelial/tract fragments postop; partial dissolution of calculi to facilitate surgical removal.

ACTIONS: dissolution of calcium by exchange of Mg2+ from irrigating solution for insoluble Ca2+ in calculus. Mg2+ salts are soluble in the citrate irrigating solution, dissolving calculus.

DISP: (Invertment & blind) irrigation: 30–50 mL via Foley, stumped for 30 mins, repelled TID for 3–5 or bladder stones; irrigation via dual nephrostomy tube (without cuffing) or into ureteral catheter with nephrostomy drainage; essential to keep pressure >80 cm H2O by manipulation.

W/P: (+, +) Caution ⇒ irrigating the renal pelvis of patients w/ impaired renal function. Observe for early signs/symptoms of hypermagnesemia (nausea, lethargy, confusion and hypotension). Severe hypermagnesemia may result in hyporeflexia, dyspnea, apneic episodes, cardiac arrest, and subsequent death. Monitor magnesium levels and deep tendon reflexes should be evaluated.

CI: Obstructed urinary tract, extravasation, UPI.

DISP: Solution: Se: Hypermagnesemia, limitation, sialosis, other infections.

NOTES: fluid solution G was modified by addition of magnesium salts to create Renacidin.

CLARITHROMYCIN (BIAxin, Biaxin LR)

USES: ↑ Upperson flap tract, skin & skin structure infections, H. pylori infections, & infections caused by nontuberculous (atypical) Mycobacterium; prevention of MAC infections in HIV infection.

DOSE:
- Adults: 250–500 mg PO BID or 1,000 mg (2 × 500 mg X tab)/t/d (Macrolide carbonic 500 mg PO PO)
- Peds: ≤ 6 mo: 7.5 mg/kg PO PO; BD; ↓ renal impairment.

W/P: (+, +) Antibiotic-associated colitis; rare ↑ QT & ventricular arrhythmias; not rec w/ PDE5 inhibitors.

Cl: Macrolide allergy; w/ H pylori w/ Biaxir; w/ aspirin, piroxicam, atorvastatin, leflunomide, ergotamines, PDE5 inhibitors (sildenafil, others); w/ corticosteroids; w/ cimetidine & renal impairment; w/ statins, ↑ QT or ventricular arrhythmias.

DISP: Tabs 250, 500 mg susp 125, 250 mg/mL; 500 mL NX tab.

SE: ↑ QT interval; causes metabolic taste, Vomiting, abdominal pain, rash.

NOTES: Multiple drug interactions; ↑ theophylline & carbamazepine levels, do not refrigerate susp.

CLINDAMYCIN (Cleocin, Cleocin-T, Others)

WARNING: Pseudomembranous colitis may range from mild to life threatening.

USES: ↑ aerobic & anaerobic infections; topical for severe acne & Vag infections.

ACTIONS: Bactericidal interferes w/ protein synthesis. Spectrum: Streptococci (eg, pneumococci, staphylococci), & (find ↔ anaerobes, no activity against gram) – aerobes.

DOSE:
- Adults: PO: 150–450 mg PO q6–8 h. IV: 300–400 mg q4–8 h ⇒ 900 mg IV q4 h. Vag cream: 1 applicator ⇒ 7 days. Vag supp: Insert 1 qhs ⇒ 3 days. Topical: Apply 1% gel, lotion, or ointm BD.

Ped: (Avoid use; contains benzyl alcohol) 10–15 mg/kg/day IV ⇒ q8–12 h. Children > 3 y: 30–50 mg/kg/d4 h ⇒ 48–49 h. ↑ to a max of 1.8 g/d PO or 4.8 g IV. Topical: Apply 1%, gel, lotion, or ointm BD, ↓ in severe hepatic impairment.
**COLLAGENASE CLOSTRIDIUM HISTOLYTICUM (XIAFLEX)**

**WARNING:** Corporal rupture, severe hematoma, mild allergic reactions (pruritus).

**NOTES:** For details of procedure see package insert; administer only by experienced provider. If the deformity < 15 degrees after any treatment cycle subsequent cycles should not be administered.  

**Ped:** Analgesic: 0.5–1 mg/kg/dose PO q4–6h PRN. Antitussive: 1–1.5 mg/kg/24h PO q4–6h max. 30 mg/24h; 1 mg renal/hepatic impairment.

**W/P:** JC: (D prolonged use or high dose at term), ox (CNS depression), Hr drug abuse, severe hepatic impairment.

**CI:** Component sensitivity.

**DISP:** Tabs: 15, 30, 60 mg; soln: 30 mg/5 mL; inj: 15, 30 mg/5 mL.

**SE:** Drowsiness, constipation, J BP.

**NOTES:** Usually combined w/ vasoepinephrine for pain or as agents (eg, terbutyl hydrazide) as an antispasmodic, 120 mg Hying 10 mg IM morphine.

---

**CODEINE [C-II]**

**USES:** Mild–mod pain; symptomatic relief of acute coronary syndrome.

**ACTIONS:** Narcotic analgesic, J cough reflex.

**DOSE:** Adults: Analgesic: 15–60 mg PO or IM q4h PRN; 360 mg max/24h. Antitussive: 10–20 mg PO q4h PRN; max. 120 mg.

**SE:** Ovarian enlargement, vasomotor flushes.

**DISP:** tabs: 0.1, 0.2, 0.3 mg.

**CI:** Component sensitivity.

**DISP:** Tabs: 0.1, 0.2, 0.3 mg.

**SE:** Drowsiness, orthostatic, J BP, serotonina, constipation, J MR, dizziness.

**NOTES:** More effective for HTN if combined w/ diuretics; withhold slowly, naranbolic HTN w/ abrupt D/C of doses >0.2 mg BID. (Duloxad oral is used for chronic, cancer pain.

---

**COLONICPHEN (CLomid, Serophene, Generic)**

**USES:** 1x ovulatory dysfunction in women desiring pregnancy.

**ACTIONS:** Nonsteroidal ovulatory stimulant; estrogen antagonists, increase FSH and LH through blocking feedback inhibition on the pituitary.

**DOSE:** 50 mg × 5 days; If no ovulation × 10 mg × 5 days @ 30 day; ovulation usually 5–10 days postcourse, time cycling w/ expected ovulation time.

**DISP:** Tabs 0.1, 0.2, 0.3 mg.

**SE:** Ovarian enlargement, vasomotor flushes.

**NOTES:** Off-label use in males to increase testosterone or for low sperm counts; >10% of men w/ azospermia and hypospermidion have return of sperm to ejaculate after 1 treatment using clomifene.

---

**CLOMIDONE, ORAL (CATEAPRS)**

**USES:** Clomiphene citrate, Clomid, Serophene, Generic.

**ACTIONS:** Clomiphene citrate, Clomid, Serophene, Generic.

**DOSE:** Adults: 50 mg/d; full effects take several days.

**ACTIONS:** D/C drug w/ diazepam, evaluate for C. diff.

---

**CODEINE [C-II]**

**USES:** Mild–mod pain; symptomatic relief of acute coronary syndrome.

**ACTIONS:** Narcotic analgesic, J cough reflex.

**DOSE:** Adults: Analgesic: 15–60 mg PO or IM q4h PRN; 360 mg max/24h. Antitussive: 10–20 mg PO q4h PRN; max. 120 mg.

**SE:** Drowsiness, constipation, J BP.

**NOTES:** More effective for HTN if combined w/ diuretics; withhold slowly, naranbolic HTN w/ abrupt D/C of doses >0.2 mg BID. (Duloxad oral is used for chronic, cancer pain.

---

**COLLAGENASE CLOSTRIDIUM HISTOLYTICUM (XIAFLEX)**

**W**arning: Corporal rupture, severe hematoma, mild allergic reactions (pruritus).

**NOTES:** For details of procedure see package insert; administer only by experienced provider. If the deformity < 15 degrees after any treatment cycle subsequent cycles should not be administered.  

**Ped:** Analgesic: 0.5–1 mg/kg/dose PO q4–6h PRN. Antitussive: 1–1.5 mg/kg/24h PO q4–6h max. 30 mg/24h; 1 mg renal/hepatic impairment.

**W/P:** JC: (D prolonged use or high dose at term), ox (CNS depression), Hr drug abuse, severe hepatic impairment.

**CI:** Component sensitivity.

**DISP:** Tabs: 15, 30, 60 mg; soln: 30 mg/5 mL; inj: 15, 30 mg/5 mL.

**SE:** Drowsiness, constipation, J BP.

**NOTES:** Usually combined w/ vasoepinephrine for pain or as agents (eg, terbutyl hydrazide) as an antispasmodic, 120 mg Hying 10 mg IM morphine.

---

---

**COLIODIGEL (PLAXIV, GENERIC)**

**USES:** ‘Reduce attherosclerotic events, acute coronary syndrome.’

**ACTIONS:** J PR aggregation.

**DOSE:** 75 mg; ACL: 350–400 mg PO loading dose, then 75 mg PO, full effects take several days.
CONIVAPTAN HCL (VAPRISOL)

- Hold pressure for 30 s and release, after 30 s repeat, repeat 3 times.
- Patient should perform self-modeling with spontaneous erection and stretch flaccid penis

CONIVAPTAN HCL (VAPRISOL)

USES: Edematous & hyponatremic hypovolemia.

ACTIONS: Dual arginine vasopressin 2 receptor antagonist.

DOSE: 20 mg IV 1–2 max. dose, then 20 mg cont for 24 h; 20 mg IV load for 1–3 more days; may ↑ 1 mg/hr if Na+ not responding; 4-day max; use, use large vial, change site q24h.

W/P: [C, ↓] Rapid↑ Na+ (12 mEq/L) may cause cardiac decompensation, impaired renal function, high aldosterone levels, CYP3A4 inhibitor.

CL: Hyponatremic hypovolemia, w/ CYP344 inhibitor, anuria.

DISP: IV 20 mg/100 mL.

SE: Ile ile reactions, headache, IVN/Dxanthea, constipation, J, K, orthostatic, J, RP, thirst, pain, dry mouth, paresthesia, pitting, infection.

NOTES: Monitor Na+, vol and neurologic status; Na+ w/ vol replacement.

CORTISONE

See Textbook Systemic and Topical Pages 968, 969

CYCLOSPORINE (GENGRAF, NEORAL, SANDIMMUNE)

WARNING: Risk nephrotoxic, risk of malignancies, risk H/TN and nephrotoxic.

USES: Organ rejection in kidney, liver, heart, rheumatoid arthritis, psoriasis.

ACTIONS: Immunosuppressant reversible inhibition of immunocompetent lymphocytes, a calcineurin.

DOSE: Adults & Peds: PO: 15 mg/kg/12 h transplantant; after 2 wk, taper by 5 mg/kg/d to 6–10 mg/kg/d or PO: 75 mg PO BID; do not chew/crush; NPO, give 1/3 PO dose IV; DID 15–30 mL/min

W/P: [C, ↓] CYP3A4 inhibitor.

CL: Decreased renal, hepatic dysfunction, cirrhosis.

DISP: Caps 25, 75 mg.

SE: Trough:
- Headache, dizziness, anxiety, nephrotox, pulm edema, pain, anaphylaxis/hypersens.
- Administer w/in 4 hr of prep.
- Follow WBC cystine or plasma cysteamine levels.
- Risk neoplasm, irreversible testicular atrophy possible; cardiotox rare; anorexia; N/V; hepatotox; rare interstitial pneumonitis; allergic reactions; anaphylaxis; rash; myalgia; headache; diarrhea; flushing; fever; hypotension; increase BUN & Cr and mimic transplant rejection; peds up to 12 yr: Maint 1.3 g/m2/d; patients with normal renal function 0.75 g/m2/d.

NOTES: Monitor renal function.

CYTOSPORIN

See Textbook Systemic and Topical Pages 988, 997

CYTOXAN, NEOSAR

WARNING: Risk aplasia, myelosuppression, risk WBC, risk of malignancies, risk H/TN, risk of malignancies.

USES: Hodgkin disease & NHLs; multiple myeloma; chronic lymphocytic leukemia, ovarian, cervical, melanoma, tumors; neuroblastoma; retinoblastoma; acute leukemias; allogeneic & ABMT in high doses; severe rheumatologic disorders (SLE, JRA, Weger granulomatosis); “internal change” nephrotic syndrome in children.

ACTIONS: Alkalizing agent.

DOSE: Adults: (per protocol) 500-1,500 mg/m2 qm o .

W/P: [C, ↓] Risk of TTP and/or thrombocytopenia.

CL: GI absorption.

DISP: Caps 25, 75 mg.

SE: Myelosuppression, N/V, anorexia, vomiting, abdominal pain, renal ischemia.

NOTES: Monitor BUN & Cr and mimic transplant rejection.

CYSTAMINE (CYSTAGON, PROCYBSI)

DOSE: Risk of thrombosis; risk of malignancies.

ACTIONS: Benemid corticosteroid.

DOSE: Benemid: 500 mg–1g/m2 qm o .

W/P: [C, ↓] Risk of TTP and/or thrombocytopenia.

CL: GI absorption.

DISP: Caps 25, 75 mg.

SE: Nausea, vomiting, anorexia and abdominal pain, lethargy.

NOTES: Follow WBC cystine or plasma cysteamine levels.

DABIGATRAN (PRADAXA)

WARNING: Pradaxa D/C if inadequate anticoagulation may 1 stroke risk, epidural or spinal hematomas may occur.

USES: ↑ Risk stroke/systemic embolism w/ nonvalvular AF; treat DVT and PE in patients who have been treated with a parenteral anticoagulant for 5–10 days.

ACTIONS: Thrombin inhibitor.

DOSE: C/O: [C, ?] QD 30 mg/m2/150 mg PO BID.

W/P: [C, ↓] Dose at 2-wk intervals; 1.8 g/m2–160 mg/kg (or 15 mg/kg/12 h pretransplant; 10.7% at 12 yr.

CL: Prevention of acute organ rejection.

DISP: Caps 75, 150 mg.

SE: Bleeding, gastritis, dyspepsia.

NOTES: See label to convert between anticoagulants; caps sensitive to humidity (30-day life span).

DACLIZUMAB (ZENAPAX)

WARNING: Administer in glass container; N/O to Sandimmune and Neoral (Sandimmun); avoid refeeding HCQ patients after D/C.

ACTIONS: Δ Proliferative activity, immunosuppression.

DOSE: Adult: 10 mg/kg IV/IM/Inj 3 times weekly; 5–10 days.

W/P: [C, ↓] Δ Risk of wound infection.

CL: GI absorption.

DISP: Caps 50, 150 mg.

SE: Trough:
- Headache, dizziness, anxiety, nephrotox, pulm edema, pain, anaphylaxis/hypersens.
- Administer in w/ IV 4 hr of prep.

DACLIZUMAB (ZENAPAX)
**DACTINOMYCIN (COSMEGEN)**

**WARNING:** Administer under skilled supervision in properly equipped facility; powder and citric acid, dextrose, mannitol, potassium hydroxide, and thiomersal; avoid exposure and use precautions.

**USES:** Choriocarcinoma, Wilms' tumor, Kaposi and Ewing sarcomas, rhabdomyosarcoma, uterine and testicular cancer.

**DOSE:**
- Adults: 15 µg/mL for 5 for 5 qh 6–8 wk or 400–600 µg/m² q4–6 wk.
- Pediatric: S/C.

**ACTIONS:** DNA-intercalating agent.

**SIDE Effects:** Hypersensitivity, pyrexia, fever, chills, abdominal pain, vomiting, diarrhea, nausea, stomatitis, anorexia, vomiting, retching, hypotension, fever, chills, rash, erythema, arthralgia, myalgia, edema, urticaria and angioedema.

**NOTES:** Classified as antibiotic but not used as antibacterial.

---

**DALBANVANCIN (DALVANCE)**

**USES:** Acute bacterial skin & skin structure infections (ABSSSI), complicated skin & skin structure infections (cABSSSI).

**DOSE:**
- Adults: 2,500–5,000 U SQ 1–2 hr.
- Pediatric: Adjust to appropriately for age and weight.

**ACTIONS:** Glycopeptide antibacterial (blocks cell wall synthesis).

**SIDE Effects:** Nausea, vomiting, anaphylaxis reported; avoid rapid inf; severe infusion reactions include hemodynamic instability, hypotension, anaphylaxis and anaphylactoid reactions.

---

**DARIFENACIN (ENABLEX)**

**USES:** Overactive bladder with symptoms of urge incontinence, urgency and frequency.

**DOSE:**
- Adults: 15 mg p.o. in 1 or 2 doses.

**ACTIONS:** Muscarinic receptor antagonist.

**SIDE Effects:** Diarrhea, constipation, dyspepsia, flatulence.

---

**DARITONTE (DANTIUM, REVONTO)**

**WARNING:** Hepatic reported; DC after 45 days. May not be beneficial.

**USES:** Treat spasticity due to upper motor neuron disorders (eg, spinal cord injury, stroke, CP, MS), malignant hyperthermia.

**DOSE:**
- Adults: 25, 40, 60, 100, 200, 300 µg/kg single IV or SQ qwk; titrate, do not exceed target Hgb of 12 g/dL; use lowest doses possible; see PI to convert from Hemoprep.

**ACTIONS:** Erythropoiesis, recombinant human EPO (rHuEPO).

**SIDE Effects:** Headache, hypertension, vertigo, chest pain, abdominal pain, back pain, myalgia, edema, edema, rash, urticaria and angioedema.

---

**DEGARELIX (FIRMAGON)**

**USES:** Advanced prostate cancer.

**DOSE:**
- Adults with mHSPC: 3.6 mg SC at baseline and 6 months.

**ACTIONS:** Reversible LHRH antagonists; LH and testosterone (obv) saw use in prostate (obv) and testicular (obv).

**SIDE Effects:** Hot flashes, sexual dysfunction, fatigue, mood swings, abdominal pain.

---

**DENOSUMAB (PROLIA, XGEVA)**

**USES:** Multiple myeloma postmenopausal women; 1 BMD in men on ADT (Prolia); prevent skeletal events in bone metastases (Xgeva).

**DOSE:**
- Prolia: 60 mg SQ giv, in upper arm, thigh, abdominal.
- Xgeva: 120 mg SQ q6mo; in upper arm, thigh, abdominal.

**ACTIONS:** RANK ligand (RANKL) inhibitor (human Fc fusion protein).

**SIDE Effects:** Tenderness, pain at injection site, subcutaneous fat atrophy, arthralgia, myalgia.

---

**DESMPRESSIN (ddAVP, DDAVP NASAL SPRAY, STIMATE)**

**USES:** Amniotic fluid levels in women with severe polyhydramnios.

**DOSE:**
- Adults: 10–40 µg/mL in 1–3 doses.
- Pediatric: 3–12 yrs:
  - 0.50–0.63 µg/mL in 1 or 2 doses.

**ACTIONS:** Nonselective LHRH receptor agonist.

**SIDE Effects:** Nausea, vomiting, diarrhea, abdominal pain, retentive, abnormal vision, dizziness, asthenia.

---

**DENTROHEMOCRINE (DANTRIUM, REVONTO)**

**WARNING:** Hepatic reported; DC after 45 days. May not be beneficial.

**USES:** Treat spasticity due to upper motor neuron disorders (eg, spinal cord injury, stroke, CP, MS), malignant hyperthermia.

**DOSE:**
- Adults: 25, 40, 60, 100, 200, 300 µg/kg single IV or SQ qwk; titrate, do not exceed target Hgb of 12 g/dL; use lowest doses possible; see PI to convert from Hemoprep.

**ACTIONS:** Erythropoiesis, recombinant human EPO (rHuEPO).

**SIDE Effects:** Headache, hypertension, vertigo, chest pain, abdominal pain, back pain, myalgia, edema, edema, rash, urticaria and angioedema.

---

**DERIVATIONS (DANTRIUM, REVONTO)**

**SIDE Effects:** Diarrhea, constipation, dyspepsia, flatulence.

---

**DEGARELIX (FIRMAGON)**

**USES:** Advanced prostate cancer.

**DOSE:**
- Adults with mHSPC: 3.6 mg SC at baseline and 6 months.

**ACTIONS:** Reversible LHRH antagonists; LH and testosterone (obv) saw use in prostate (obv) and testicular (obv).

**SIDE Effects:** Hot flashes, sexual dysfunction, fatigue, mood swings, abdominal pain.

---

**DENOSUMAB (PROLIA, XGEVA)**

**USES:** Multiple myeloma postmenopausal women; 1 BMD in men on ADT (Prolia); prevent skeletal events in bone metastases (Xgeva).

**DOSE:**
- Prolia: 60 mg SQ giv, in upper arm, thigh, abdominal.
- Xgeva: 120 mg SQ q6mo; in upper arm, thigh, abdominal.

**ACTIONS:** RANK ligand (RANKL) inhibitor (human Fc fusion protein).

**SIDE Effects:** Tenderness, pain at injection site, subcutaneous fat atrophy, arthralgia, myalgia.

---

**DESMPRESSIN (ddAVP, DDAVP NASAL SPRAY, STIMATE)**

**USES:** Amniotic fluid levels in women with severe polyhydramnios.

**DOSE:**
- Adults: 10–40 µg/mL in 1–3 doses.
- Pediatric: 3–12 yrs:
  - 0.50–0.63 µg/mL in 1 or 2 doses.

**ACTIONS:** Nonselective LHRH receptor agonist.

**SIDE Effects:** Nausea, vomiting, diarrhea, abdominal pain, retentive, abnormal vision, dizziness, asthenia.
**DEXAMETHASONE (DECADRON)**

See steroids, Spernic and steroids, Topical: Pages 968, 969.

**DEXAMETHASONE (DECADRON)**

**USES:**

- Minimize paralytic ileus, Treat postoperative ileus.

**ACTIONS:**

- Cholinergic agent.

**DOSE:**

- Relief of pain: 2–3 tabs PO TID. Present postoperative ileus: 250–500 mg IM stat, repeat in 2 hr; then q8h PNI, IM: 500 mg IM stat, repeat in 2 hr; then q8h IM.

**W/P:**

- Cef: Hemophilic, mechanical bowel obstr.

**DISP:**

- 150 mg IM; cream 2% (Parabrodin chew [OTC]).

**SIDE EFFECTS:**

- GI cramps, heartburn, rash, GI ulceration, urinary retention.

**NOTES:**

- Do not crush tabs, watch for GI bleed; check CBC, U/S.

---

**DILTIAZEM (CARDIZEM, CARDIZEM CD, CARDIZEM LA, CARDIZEM SR, CARTIA XT, DILACOR XR, DILTIA XT, TAZTIA XT, TIZAC)**

**USES:**

- Angina, prevention of reinfarction, HTN, AF or A flutter.

**ACTIONS:**

- Calcium channel blocker.

**DOSE:**

- HTN: 2R 120–360 mg PO BID, 1 to 360 mg PO max. 2R or XR: 120–380 mg PO max. 540 mg PO or LA 180–360 mg PO.

**W/P:**

- CEF: + Effect w/ amiodarone, diltiazem, ranolazine, tiotidine, digoxin, H blockers, thiazides.

**CI:**

- All blocks, AM, R patient.

**DISP:**

- Cardizem CD: Caps 120, 180, 240, 300, 360 mg; Cardizem LA: Tabs 120, 180, 240, 360, 420 mg; Cardizem SR: Caps 60, 90, 120 mg; Cardizem: Tabs 10, 60, 90, 120 mg; Cartia XT: Caps 120, 180, 240, 300 mg; Dilacor-XR: Caps 120, 180, 240 mg; Ziac: Tabs 120, 180, 240, 300, 360, 420 mg, 540 mg; Taztia XT: 120, 180, 240, 300, 360 mg.

**SE:**

- Sinus hypoplasia, AV block, ECG abnormalities, peripheral edema, dizziness, headache.

**NOTES:**

- Cardizem CD, Dilacor XR, Tiazac not interchangeable.

---

**DIMETHYL SULFOXIDE (DMSO) (RIMSO-50)**

**USES:**

- Intravenous cystoscopy.

**ACTIONS:**

- Sterilizes.

**DOSE:**

- Intratwuos, 50 ml retain for 15 min; repeat q2hr until relief.

**W/P:**

- CEF: + See cystitis, w/ urinary retention.

**CI:**

- Component sensitivity.

---

**DIPHENHYDRAMINE (BENADRYL, GENERIC) [OTC]**

**USES:**

- Treat & prevent allergic reactions, motion sickness, postoperative nausea, sedation, cough suppression, Thrust of extrapontal reactions.

**ACTIONS:**

- Anticholinergic, antihistamine.

**DOSE:**

- Adults: 25–50 mg PO, IM or IM-TID-QID.

**Ped:**

- 2 yr: 0.5–1 mg/Kg/24 hr PO or IA – QID (max. 300 mg/d, ↓ during infancy w/ minimal-severe renal insufficiency).

**W/P:**

- CEF: Elderly, narrow-angle glaucoma, BPH, or MAOIs.

**CI:**

- Acute asthma.

**DISP:**

- Tabs & caps 25, 50, 100; chew tabs 12.5 mg, oral 6.25 mg PO, 25 mg PO or IM; 12.5 mg PO or IM; 12.5 mg/mL; IM; 50 mg/mL cream, gel, inj 2%.
DIPHENOXYLATE/ATROPINE (LOMOTIL, LONOX, GENERIC) [C-V]

USES: Sensitivity to meds w/ polysorbate 80, component sensitivity.

CI:

W/P: Elderly, w/ renal impairment.

DOSE:

ACTIONS:

USES:

∗

NOTES:

DORIPENEM (DORIBAX)

USES: Complicated intra-abdominal infection and G1 including pelvic.

ACTIONS:

USES:

NOTES:

SE:

DISP:

DOSE:

ACTIONS:

USES:

†

NOTES:

DOXAZOSIN (CARDURA, CARDURA XL, GENERIC)

USES: Hypertension.

ACTIONS: α-1-Adrenergic blocker; relaxes bladder neck smooth muscle.

USES:

∗

NOTES:

DOXORUBICIN (ADRIMYACIN, GENERIC)

USES: Acute leukemias; Hodgkin disease & NHLs; soft tissue, osteo & body carcinomas; Wilms' tumor; neuroblastoma; bladder, breast, ovarian, gastric, thyroid, & lung cancers*; intravesical for bladder cancer.

ACTIONS: Interleukin DNA; DNA topoisomerase I & II.

DOSE:

†

NOTES:

DOXYCYCLINE (ADOXA, ORACEL, VIBRAMYCIN, VIBRA-TABS)

USES: Broad-spectrum antibiotic*; acne vulgaris, uncomplicated UTI, chlamydia, PID, lymphocytic inflammation, anthrax, malaria prophylaxis.

ACTIONS: Tetracycline; bacteriostatic; spectrum: Limited gram (+) and (−), Rickettsia sp, Chlamydia sp, Mycoplasma, B. anthracis.

DOSE:

NOTES:

d-PENICILLAMINE (CUPRIMINE, DEPEN)

WARNING: Physicians planning to use penicillamine should thoroughly familiarize themselves with its toxicity, special dosage considerations, and therapeutic benefits. Penicillamine should never be used casually. Each patient should remain under the close supervision of the physician. Patients should be warned to report promptly any symptoms suggesting toxicity.

ACTIONS: Chelating agent.

DOSE:

NOTES:

d-PENICILLAMINE (CUPRIMINE, DEPEN)

WARNING: Physicians planning to use penicillamine should thoroughly familiarize themselves with its toxicity, special dosage considerations, and therapeutic benefits. Penicillamine should never be used casually. Each patient should remain under the close supervision of the physician. Patients should be warned to report promptly any symptoms suggesting toxicity.

ACTIONS: Chelating agent.

DOSE:

NOTES:

d-PENICILLAMINE (CUPRIMINE, DEPEN)

WARNING: Physicians planning to use penicillamine should thoroughly familiarize themselves with its toxicity, special dosage considerations, and therapeutic benefits. Penicillamine should never be used casually. Each patient should remain under the close supervision of the physician. Patients should be warned to report promptly any symptoms suggesting toxicity.

ACTIONS: Chelating agent.

DOSE:

NOTES:

939
DUOXETINE (CYMBALTA)

SE: Allergic reactions in up to 39%; azoselerosis, aplastic anemia, dizziness, diarrhea, abdominal pain, dermatologic manifestations, nephrotic syndrome.

NOTES: Do not discontinue therapy in; interruptions of a few days can cause hypersecretion with re-emergence of therapy; monitor CBC, CRP (proteins, hematologic, urinary, systemic levels), use PTH/8 if intact or use parathyroid.

DULOXETINE (CYMBALTA)

WARNING: antidepressants may ↑ risk of suicidality; consider risk/benefit of use. Easily monitor for clinical worsening, suicidality, or behavior change, not for peels.

USES: Depression, diabetic peripheral neuropathic pain, generalized anxiety disorder (GAD), fibromyalgia, chronic osteoarthritic & back pain.

ACTIONS: Selective serotonin & norepinephrine reuptake inhibitor (SSNRI).

DOSE: Depression: 60–40 mg PO; 80–60 mg PO; 120 mg/d; Fibromyalgia, Osteoarthritis/back pain: 60 mg/d PO; neuropathy: changes; not for peds.

USES: Treatment of moderate to severe chronic pain.

ACTIONS: Sympathomimetic; stimulates α & β receptors; bronchodilator.

DOSE: Adults: 0.25–1 mg/kg IV; 1.25–10 mg IV/q4h; Peds: 0.05–0.1 mg/kg IV PO q2–4h; ↑ in renal impairment.

ECONAZOLE (ECOZA, SPECTAZOLE, GENERIC)

USES: Tinea, candidiasis, & tinea versicolor infections.

ACTIONS: Antifungal.

DOSE: Topical formulations 0.5–1% BID q4–24h.

EMLA (LIDOCAINE 2.5%, PRilocaine 2.5%, GENERIC)

USES: nummular eczema, dysesthesias.

ACTIONS: Topical anesthetic.

DOSE: Apply to areas BID q12h.

ENZALUTAMIDE (XTANDI)

USES: Metastatic castration-resistant prostate cancer w/ or w/o previous docetaxel.

ACTIONS: Androgen receptor inhibitor.

DOSE: Oral (only) 160 mg daily, do not chew/nail caps.

EPIPHEN (EPHEDRINE, GENERIC)

USES: Acute bronchospasm, bronchial asthma, nasal congestion, ↑ BP, nasal spray, ephedrine, & isoprenaline gels.

ACTIONS: Symptomomimetic; stimulates β1 receptors; bronchodilators.

DOSE: Adults: 12.5–25 mg PO q4h PRN expectorant; 1–2 mg/kg IV q1–2h; 30–60 mg IM q2–4h; 0.5–1 mg/kg SQ q6–12h; 100–200 mg SC q4–6h.

ENOXAPARIN (LOVENOX)

USES: Recent or anticipated epidural/spinal anesthesia, ↑ risk of spinal epidural hematoma w/ subsequent paralysis.

ACTIONS: LMW heparins; inhibit thrombin by complexes w/ antithrombin III.

DOSE: Adults: Prevention & Treat of DVT; Treat PE: unstable angina & non-Q SBMI.

WARNING: Recent or anticipated epidural/spinal anesthesia, ↑ risk of spinal epidural hematoma w/ subsequent paralysis.

USES: Prevention & Treat of DVT; Treat PE: unstable angina & non-Q SBMI.

ACTIONS: LMW heparins; inhibit thrombin by complexes w/ antithrombin III.

DOSE: Adults: Prevention: 30 mg SQ 12 or 40 mg SQ BID; DVT/PE Treat: 1 mg/kg SQ 2H or 1.5 mg/kg SQ 4H; SCI: 30 mL/m² 1 to 1.5 mg/kg SQ 4H.

Ped: Prevention: 0.5 mg/kg SQ 2H; DVT/PE Treat: 1 mg/kg SQ 2H; 2 dose w/ SCI: 30 mL/m².

W/P: [C, ?] not for prophylaxis in prosthetic heart valves.

CI: Active bleeding, heparin induced thrombocytopenia-Ah, heparin, clot, skin, mass.

DISP: IV 10 mg/1 mL; SQ 0.5 mg/kg SQ 12H; 120, 150 mg SQ; 300 mg/mL multi-dose vial.

SE: Bleeding, hemarthrosis, bruising, thrombocytopenia, local, pain/hematoma at site, ↑ A/G.

NOTES: ↑ risk on bleeding time, function, PT, or aPTT; monitor SIH for heparin-induced thrombocytopenia, clinical bleeding, may monitor antifactor Xa kit for PT.
EPOETIN ALFA (Erythropoietin, Epo) (EPOGEN, PROCRIT)

**WARNING:** Inj. Morbidity, serious CV thromboembolic events, and tumor progression. Renal failure pts experienced greater risks (death/CV events) on erythropoiesis-stimulating agents (ESA) to target Hgb 11 g/dL, Maintain Hgb 10–12 g/dL. In cancer pts, ESA survival advantage progression in some cancer when dosed Hgb > 2 g/dL. Use lowest dose needed. Use only for myelosuppressive some cancer when dosed Hgb

ESAs dose needed. Use only for myelosuppressive some cancer when dosed Hgb

In cancer pt, ESAs target Hgb levels 11 g/dL. Maintain Hgb 10–12 g/dL.

thrombocytosis, ↑ Can give IM
ESTRADIOL, SPRAY (EVAMIST)

WARNING: Risk endometrial cancer. Do not use to prevent CV disease or dementia. ↑ risk MI, stroke, breast cancer (PL), and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥ 65 yr).

USES: Vasomotor sx in menopause.

ACTIONS: Estrogen supl.

DOSE: Spray on inner surface of forearm. 
W/P: [X, ↓–↓] May ↑ PT/PTT aggregation w/ thyroid disease.

CI: Unspecified genitai bleeding, breast cancer, estrogen-dependent tumors, thromboembolic disorders, thrombophlebitis, recent MI, pregnancy, severe hepatic disease.

DISP: 1.9 mg spray [16–spray container].

NOTES: Contains alcohol; caution around flames until dry; not for Vag use.

ESTRADIOL, TRANSDERMAL (ALORA, CLIMARA, ESTRADERM, VIVELLE DOT)

WARNING: Risk endometrial cancer. Do not use to prevent CV disease or dementia. ↑ risk MI, stroke, breast cancer (PL), and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥ 65 yr).

USES: Severe menopausal vasomotor sx; female hypogonadism.

ACTIONS: Estrogen supl.

DOSE: Start 0.0375 mg/24 h patch ↑ to 0.05–0.075 mg/24 h w/ intact uterus cycle 3 wk ↑ 0.1 mg/24 h/wk. 
W/P: [X, ↓–↓] May ↑ PT/PTT aggregation w/ thyroid disease; toxic shock reported.

CI: Unspecified genitai bleeding, breast cancer; estrogen-dependent tumors; thromboembolic disorders; thrombophlebitis, recent MI, pregnancy, severe hepatic disease.

DISP: 1 patch 1–2 wk.

NOTES: Contains alcohol; caution around flames until dry; not for Vag use.

ESTRADIOL, VAGINAL (ESTRING, FEMRING, VAGIFEM)

WARNING: Risk endometrial cancer. Do not use to prevent CV disease or dementia. ↑ risk MI, stroke, breast cancer (PL), and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥ 65 yr).

USES: Postmenopausal Vag atrophy (EstrinG™), vulvar and vaginal atrophy associated w/ menopause (Ferring™), atrophic vaginitis (Vagifem™).

ACTIONS: Estrogen supl.

DOSE: Estring: Insert ring into upper 3rd of Vag vault; remove and replace after 90 d; reassess 3–6 mo. 
W/P: [X, ↓–↓] May ↑ PT/PTT aggregation w/ thyroid disease; toxic shock reported.

CI: Unspecified genitai bleeding, breast cancer; estrogen-dependent tumors; thromboembolic disorders; thrombophlebitis, recent MI, pregnancy, severe hepatic disease.

DISP: Estring ring: 0.0075 mg/24 h, Ferring ring: 0.05 and 0.1 mg/24 h [Ferring 10 μg].

SE: Headache, leukorhea, back pain, candidiasis, vaginitis, Vag discomfort/hemorrhage, arthralgia, insomnia, abdominal pain; see estradiol, oral notes.

ESTRADIOL/LEVONORGESTREL, TRANSDERMAL (CLIMARA PRO)

WARNING: Risk endometrial cancer. Do not use to prevent CV disease or dementia. ↑ risk MI, stroke, breast cancer (PL), and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥ 65 yr).

USES: Menopausal vasomotor sx; prevent postmenopausal osteoporosis.

ACTIONS: Estrogen & progestrone.

DOSE: 1 patch ↑ to 4 wk.
W/P: [X, ↓–↓] thyroid.

CI: AUB, estrogen-sensitive tumors, he thromboembolism, liver impairment, pregnancy, hypertension.

DISP: Estraderm 0.045 mg/levonorgestrel 0.015 mg/day patch.

SE: Site reaction, Vag bleeding, spotting, breast changes, abnormal bleeding/spotting, headache, retention fluid, edema, ↑ BT.

NOTES: Apply to lower abdomen; for osteoporosis give CA2+↑ BT↓ sup; follow breast exams.

ESTRADIOL/NORETHINDRONE (ACTIVELLA, FEMHRT, GENERIC)

WARNING: Risk endometrial cancer. Do not use to prevent CV disease or dementia. ↑ risk MI, stroke, breast cancer (PL), and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥ 65 yr).

USES: Menopausal vasomotor sx; prevent postmenopausal osteoporosis.

ACTIONS: Estrogen/progestrone; plant derived.

DOSE: 1 tab start w/ lowest dose combo.
W/P: [X, ↓–↓] ↑ BT↑ PTH↑. 
CI: Pregnancy; he breast cancer; estrogen-dependent tumor; abnormal genitai bleeding; he DVT, he OR related disorder; recent (≤ 15 yr) arterial thromboembolic disease (CVs, MI).

DISP: Femhrt: Tab. 2.5/0.1, 2.5/0.3 mg ↓ BT↓ PTH↑. 
ACTIVELLA: Tabs: 10/0.5, 0.5 mg/0.1 mg.

SE: Thrombosis, dizziness, headache, blood changes, insomnia, emotional instability, breast pain.

NOTES: Use in women w/ intact uterus; caution in heavy smokers; combo also used as oral contraceptive.

ESTRAMUSTINE PHOSPHATE (EMCYT)

USES: Palliative treatment of metastatic and/or advanced carcinoma of the prostate.

ACTIONS: Estradiol w/ nitrogen mustard; exact mechanism unknown.

DOSE: 0.4 mg/kg/d in 3–4 doses; on empty stomach, no dairy products.
W/P: [X, ↓–↓] not used in females.
CI: Active thromboembolism or thromboembolic disorders.

DISP: Caps 140 mg.
SE: ↑ N/V; exacerbation of pre-existing CHF, edema, hepatic disturbances, thrombophlebitis, MI, PE, gynecomastia in 20–100%.

NOTES: Low-dose breast irradiation before may ↓ gynecomastia.

ESTROGEN, CONJUGATED (PREMARIN)

WARNING: Risk endometrial cancer. Do not use to prevent CV disease or dementia. ↑ risk MI, stroke, breast cancer (PL), and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥ 65 yr).

USES: Mid–severe menopausal vasomotor sx; atrophic vaginitis; hypogonadism; palliation of advanced breast and prostate cancer; prevention osteoporosis.

ACTIONS: Estrogen replacement.

DOSE: 0.3–1.25 mg PO; Intramuscular cream 0.5–2 g x 21 days, then off x 7 days or 0.5 mg twice weekly.
W/P: [X, ↓–↓] thyroid.

CI: Severe hepatic impairment, genitai bleeding of unknown cause, breast cancer; estrogen-dependent tumors, thromboembolic disorders, thrombosis, thrombophlebitis, recent MI.

DISP: Caps 0.3, 0.45, 0.625, 0.9, 1.25 mg; Vag cream 0.625 mg/d.
SE: ↑ Risk of endometrial cancer, galbladder disease, thromboembolism, headache, & possibly breast cancer.

NOTES: Generic products not equivalent.

ESTROGEN, CONJUGATED/ MEDROXYPGROGESTERONE (PREMPRO, PREMPHASE)

WARNING: Risk endometrial cancer. Do not use to prevent CV disease or dementia. ↑ risk MI, stroke, breast cancer (PL), and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥ 65 yr).

USES: Mid–severe menopausal vasomotor sx; atrophic vaginitis; prevent postmenopausal osteoporosis.

ACTIONS: Hormonal replacement.
FENTANYL, INJECTION (SUBLIMAZE, GENERIC) [C-II]

DOSE: Prempro 1 tab PO daily, Premphase 1 tab PO daily.
W/P: [K, L].
CI: Severe hepatic impairment, genital bleeding of unknown cause; breast cancer, estrogen-dependent tumors; thromboembolic disorders, thrombosis, thrombophlebitis.

DOSE: [As estrogen/progestogen replacement] Prempro: Tabs 0.315, 0.451/3, 0.625/2.5, 0.625/5 mg; Premphase: Tabs 0.625/10 (days 1–14) & 0.625/5 mg (days 15–28).
SE: Gallbladder disease, thrombembolism, headache, breast tenderness.
NOTES: See WHI (www.whi.org); use lowest dose/timeframe possible.

ESTROGEN, CONJUGATED SYNTHETIC (CENESTIN, ENUUVIA)

WARNING: 1 Risk endometrial cancer: Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). 2 Dementia risk in postmenopausal (≥70 yr).

USES: Vaginosis, perineal swelling, vulvovaginal atrophy.

ACTIONS: Multiple estrogen replacement.

DOSE: For all w/ intact uterus: Prempro = 10–14 days/28-day cycle; Premphase: Tabs 0.625–1.25 mg (Enjuvia vasomotor: 10–14 days/28-day cycle; 50–79 yr). 2 Dementia risk in postmenopause (≥50 yr).

DOSE: [C, ?/L].

SE: Headache, hyperuricemia, acute gout, abdominal pain, ↑ BP; risk MI, stroke, dementia.

DOSE: 0.3 mg/d.

ETOPOSIDE [VP-16] (ETOPOPHOS, GENERIC)

WARNING: Should be administered under the supervision of a qualified physician experienced in the use of chemotherapy. Severe myelosuppression with resulting infection or bleeding may occur.

USES: Small cell lung cancer; testicular cancer; Hodgkin disease; NHLs, peds ALL, & BMT in high dose.

ACTIONS: Topoisomerase II inhibitor.

DOSE: 50–150 mg/m² IV 3–5 days; 50 mg/m² PO for 21 days (PO availability = 50% of IV; ≥ 46 gm² or 25–20 mg/kg in IM (per protocol); ↑ in renal/hepatic impairment.
W/P: [K, L].
CI: ↑ blood pressure.

EVEROLIMUS (AFINITOR, AFINITOR DISPERZ)

USES: 1 Afinitor: Hormone receptor positive, HER2-negative breast cancer w/ or without an endocrine therapy; unresectable progressive neuroendocrine tumors of pulmonary origin (PNET); advanced renal cell carcinoma (RCC) after failure of targeted therapy; adult patients w/ angiosarcoma, or lobular breast cancer, and tuberous sclerosis complex (TSC), not requiring immediate surgery, Afinitor and Afinitor Disperz: Pediatric and adult w/ tuberous sclerosis complex (TSC) who have subependymal giant cell astrocytoma (SEGA) that requires therapeutic intervention but cannot be resected.

ACTIONS: mTOR inhibitor.

DOSE: 10 mg PO daily, ↓ to 5 mg w/ or without a decrease in risk of death (see also everolimus)
W/P: [K, L].

SE: Hypertension, creatinine, ↑ serum cholesterol, ↑ triglycerides, ↑ diabetes, ↑ lab tests; ↑ AMI, stroke, MI.

EVEROLIMUS (ZORTRESS)

USES: Prevent renal and liver transplant rejection; combo w/ basiliximab w/ ↓ incidence of transfusions due to chronic rejection.

ACTIONS: mTOR inhibitor (mammalian target of rapamycin).
**FENTANYL, TRANSDERMAL (DURAGESIC, GENERIC) [C-II]**

**WARNING:** Potential for abuse and fatal OD; resp depression possible; use w/ CYP3A4 inhibitors (or discontinuation of CYP3A4 inducers) to prevent initial titration. Initiation of CYP3A4 inhibitors (or discontinuation of CYP3A4 inducers) can result in a fatal OD; avoid use in application site, can cause OD.

**USES:** Persistent mod-severe chronic pain in pts already tolerant to opioids.

**DOSE:** Apply patch to upper torso ≥24h; dose based on narcotic requirements in previous 24 h; start 25 μg patch of 20; ↓ in renal impairment.

**W/P:** [B, ↑] w/ CYP3A4 inhibitor or CV CYP3A4 inducer may ↑ fentanyl effect, w/ Hx substance abuse.

**Cl:** Not topical tolerant, short term pain management, postoperative pain in outpatient surgery, mild pain, PONV use, ↑ 1CYP; resp depression, severe renal/hepatic impairment, pediatrics; ↓ 2–3 yrs.

**DISP:** Patches 12.5, 25, 50, 75, 100 μg/h.

**SE:** Head press (can be fatal), sedation, ↓ BP, ↓ HR, constipation, N/V.

**NOTES:** 0.1 mg fentanyl = 10 mg IM morphine. Do not cut patch; peak level in PREGNANCY 24–72 h.

---

**FERRIC CARBOXYMALTOSE (INJECTAFER)**

**USES:** Use of deficiency anaemia.*

**ACTIONS:** Fe Supl.

**DOSE:**
- **Adults:** 500–1000 mg elemental Fe or 7.5 mg/kg over 30 min after inf.
- **Children:** 2.25 mg/kg over 15–30 min after inf.

**Cl:** Component hypersensitivity; Fe absorption w/ vit C; Fe absorption w/ tetracycline, fluoroquinolones, antacids, H2 blockers, proton pump inhibitors.

**SE:** Head press, flushing, hypophosphatemia, dizziness, HTN.

---

**FERRIC GLUCONATE (FERGON, OTHERS)**

**WARNING:** Accidental OD of iron-containing products is a leading cause of fatal poisoning in children ≤6 yr. Keep out of reach of children.

**USES:** Use of deficiency anaemia & Fe suppl.*

**CI:** Hemochromatosis, hemolytic anemia.

**DISP:** IV 30 mg/mL. (510 mg elemental Fe/kg/d) max. 2 doses daily–TID; on empty stomach.

**SE:** Head press, flushing, hypophosphatemia, dizziness, HTN.

---

**FERROUS SULFATE (OTC)**

**USES:** Use of deficiency anaemia & Fe suppl.*

**ACTIONS:** Dietary suppl.

**DOSE:**
- **Adults:** 510 mg IV × 1, then 510 mg IV × 1 3–8 days later; give 1 ML/s.
- **Children:** 2.25 mg/kg over 15–30 min after inf.

**Cl:** Monitor for hypersens & Fe BP for 30 min after dose, may alter MRI studies.

**SE:** Head press, flushing, hypophosphatemia, dizziness, HTN.

---

**FESOTERODINE (TOVIAZ)**

**USES:** Overactive bladder w/ urge urinary incontinence, urgency, frequency.*

**ACTIONS:** Competitive muscarinic receptor antagonist; w/ bladder muscle contractions.

**DOSE:** 4 mg PO qd, ↑ to 8 mg PO daily PRN.

**Cl:** [C, ↑] Avoid in prnl w/ severe renal insufficiency or w/ CV CYP3A4 inducer (eg, ketoconazole, clarithromycin); w/ bladder outlet obstruction, ↓ GI motility/constriction, narrow-angle glaucoma, myasthenia gravis.

**Cl:** Urinary retention, or uncontrolled narrow-angle glaucoma, hypersens to class.

**DISP:** Tabs 4, 8 mg.

**SE:** Dry mouth, constipation, ↓ sweating may cause heat prostration.

---

**FIDACOMICIN (DIFIDIC)**

**USES:** Gram-positive infection-associated diarrhea.*

**ACTIONS:** Marizole antibiotic.

**DOSE:** 200 mg PO BID × 10 days.

**W/P:** [B, ↓] Not for systemic infection or <14 yr; to ↑ resistance, use only when diagnosis suspected/ proven.
FINASTERIDE (PROSCAR, GENERIC, PROPECIA)

USES: 
- HHM & androgenetic alopecia.

ACTIONS: 
- 5α-reductase.

DOSE: 
- PB: 5 mg PO. 
- Allopase: 1 mg PO; food increases absorption.

W/P: 
- [X, ] — Hepatic impairment.

Cl: 
- Pregnant women should avoid handling pills, lest estrogen-to-mask feil.

DISP: 
- Tabs 1 mg (Propecia), 5 mg (Proscar).

Cl: 
- libido, wt ejaculate, erectile dysfunction, gynecomastia; may slightly ↑ risk of high-grade prostate cancer.

NOTES: 
- Both 5 PSA by ~50%; receiveable PSA baseline 6 mo (double PSA to "true" reading).
- 3–6 mo for effect on urinary flow; continue to maintain new flow; clot for use in women.

FLAVOXATE (GENERIC)

USES: 
- Relief of sx of biliary, urinary, rectal, postoperative pain, urinary frequency, incontinence.

ACTIONS: 
- Antispasmodic.

USES: 
- Relief of Sx of dysuria, urgency, nocturia, suprapubic pain, urinary frequency, incontinence.

DOSE: 
- Adult: 50–100 mg PO 1–2 mo.

W/P: 
- [B, ] — Irritant chemotherapy, W/P: [X, ]

CI: 
- [D, ?] Irritant chemotherapy, W/P: [X, ]

DISP: 
- Cream 0.5, 1, 5%; soln 1%, 2%, 5%.

CI: 
- Indications: pregnancy, serious infection, biliary, thrombocytopenia, major surgery w/in past mo, G6PD, infections, MAOI.

NOTES: 
- Spontaneous abortions in peds.

FLUCONAZOLE (DIFLUCAN, GENERIC)

USES: 
- Candidiasis (oral, cutaneous), actinomycosis, oral thrush, tinea, tinea versicolor.

ACTIONS: 
- Antifungal; 1, cytochrome P-450 steroid metabolism.

USES: 
- Basal cell carcinoma (when standard therapy impractical), actinomycosis keratitis; carcinoma in situ (CIS) of the penis.

ACTIONS: 
- Inhibits thymidylate synthetase (7, DNA synthesis).

NOTES: 
- Healing may not be evident for 1–2 mo; wash hands thoroughly, avoid occlusive dressings; do not overuse; typical penile regimen describes: apply 12 hr every 48 hr for 28 days.

FLUCORTOLONE ACETATE (GENERIC)

USES: 
- Adrenocortical insufficiency, Addison disease, self-feeding adrenocortical syndrome.*

ACTIONS: 
- Mineralocorticoid.

DOSE: 
- Adult: 0.1–0.2 mg PO.

W/P: 
- [C, ] — ↑ risk of high-grade prostate cancer.

Fluocortolone: 
- 0.05–0.1 mg/d PO.

Flucortolone: 
- 0.1–0.2 mg/d PO.

Cl: 
- Systemic fungal infections; known hypersensitivity.

DISP: 
- Tabs 0.1 mg.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 0.1 mg.

SE: 
- HTN, edema, CCF, headache, dizziness, convulsions, acne, rash, bruising, hyperglycemia.

DISP: 
- Cream 0.5, 1, 5%; soln 1%, 2%, 5%.

Cl: 
- Men with carcinomas of the breast or with overt carcinoma in situ, male hypogonadism, prostatectomy, delayed puberty in males; postmenopausal metastatic breast cancer.

USES: 
- Synthetic androgen; 
- 5α-reductase inhibitor.

ACTIONS: 
- Inhibits thymidylate synthetase (7, DNA synthesis).

NOTES: 
- Closely monitor for worsening depression or emergence of suicidality, particularly in ped.

FLUXOXYMESTERONE (GENERIC) (C-I, III)

USES: 
- Hypogonadism (primary, hypogonadotropic), delayed puberty in males, postmenopausal metastatic breast cancer.*

ACTIONS: 
- Synthetic androgen; ↓ secretion of LH & FSH (feedback inhibition).

DOSE: 
- Breast cancer: 10–40 mg/d × 1–3 mo. 
- Hypogonadism: 2–30 mg/d.

W/P: 
- [X, ] — ↑ risk of high-grade prostate cancer.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 10 mg.

W/P: 
- [C, ] — ↑ risk of high-grade prostate cancer.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 20 mg/d.

Cl: 
- Men with carcinomas of the breast or with known/unexpected prostate cancer; women who are/are becoming pregnant.

DISP: 
- Tablets 100, 150, 200 mg: susp 10, 20 mL; 250 mg PO TID (750 mg total).

Cl: 
- Common: 0.5, 1, 5%; rarer: 1%, 2%, 5%.

Cl: 
- Abrupt discontinuation.

SIDE EFFECTS: 
- N/V, abdominal pain, GI bleed, anemia, reticulocytosis.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 0.1 mg.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 0.1 mg.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 0.1 mg.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 10 mg.

Flucortolone: 
- Flucortolone: 
- Flucortolone: 
- Tabs 20 mg/d.

FONDAPARINUX (ARIXTRA)  

**USES:** Thromboprophylaxis in hip replacement, abdominal surgery; w/ DVT or PE in cardiothoracic surgery.

**DOSE:** Po: 5 mg SQ daily; in renal impairment.

**ACTIONS:** Protein cross-linking.

**CI:** Severe hepatic impairment.

**DISP:** Caps 125 mg.

FOSFOMYCIN (MONUROL, GENERIC)  

**USES:** Uncomplicated UTI in women.

**DOSE:** 1 mg/kg PO q6–12h or 2 mg/kg PO q24h (max. 6 mg/kg/dose).

**ACTIONS:** ACE inhibitor.

**CI:** Hypotension, peritonitis, ileus.

**DISP:** Caps 250, 500 mg; soln 250 mg/5 mL; TID, 50 mg/kg/d max.

FOSYNA (GENERIC)  

**USES:** Intraocular implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg.

GANCICLOVIR (CYTOVENE, VITRASERT, GENERIC)  

**USES:** Herpes, CMV, adenovirus.

**DOSE:** 5 mg/kg IV q8h; 2 mg/kg dose PO q3–24h (max. 6 mg/kg/dose), ↓ dose in renal impairment.

**ACTIONS:** Antiviral.

**CI:** Hypocalcemia, ↑ K+.

**DISP:** Tablets 20, 40, 80 mg; soln 10 mg/mL.

GEMICITABINE (GENMAR, GENERIC)  

**USES:** Plasmocytic cancer (single agent), breast cancer w/ paclitaxel, WSCD w/ cisplatin, ovarian cancer w/ carboplatin, gastric cancer, urothelial carcinoma (systemic and intravesical).

**DOSE:** 1,000–2,500 mg/m² over 30–60 min–1/hr IV infusion × 3–4 wk or 4–6 wk, ↓ dose based on hematologic function (per protocol).

**ACTIONS:** Antineoplastic, nucleoside metabolic inhibitor, ↓ ribonucleotide reductase, produces false nucleoside base-inhibiting RNA synth.

**CI:** ↓ renal/cisplatin, gastric cancer, hepatic impairment.

**DISP:** Tablets 3–12 yr: 0–15 mg/kg/d × 10; over 3 days, 3–4 yr: 15 mg/kg/d × 3; ≥ 5 yr: 25–35 mg/kg/d × 10; 50 mg/kg/d max, ↓ in renal impairment.

GEPACTIN (NERVENTIN, GENERIC)  

**USES:** Postoperative neuroaplasia (PNAH) adjacent in partial seizure; chronic pain synds.

**DOSE:** Anticonvulsant; GABA analog.

**ACTIONS:** Sodium channel blocker; ↓ seizure frequency.

**DISP:** Tablets & Peds: > 12 yr: Anticonvulsant: 300 mg PO TID; ≥ max. 600 mg, Peds: 300 mg/day, 300 mg BID day 1, 330 mg BID day 2, 300 mg TID day 3, intrave 1,800–3,600 mg/d.

GEMSA (OSO/OSYO)  

**ACTIONS:** Cough, dizziness, angioedema, rash.

**CI:** Hereditary/idiopathic angioedema or angioedema w/ C1 esterase deficiency.

**DISP:** Tablets 10, 20, 40 mg.

GENERIC)  

**USES:** Hypertension, diabetic nephropathy.

**DOSE:** 10 mg PO initial, max. 40 mg PO/d; ↓ in elderly, ↓ in renal impairment.

**ACTIONS:** Bladder fibrosis, skin irritation with contact, reflux resulting in azotemia, vesical fibrosis or obstruction or papillary necrosis; extravesical causation perineal fistulas.

**CI:** Severe hepatic impairment.

**DISP:** Caps 100, 300, 400 mg; soln 250 mg/5 mL; scored tabs 600, 800 mg.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic; ↓ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**CI:** Renal dysfunction.

**DISP:** Tablets 20, 40, 80 mg.

GENERIC)  

**USES:** CMV retinitis in patients w/ AIDS.

**DOSE:** Following induction, 1,000 mg PO TID.

**ACTIONS:** ↑ BP , hyperglycemia,↑ K+.

**CI:** Components sensitive.

**DISP:** Caps 250, 500 mg; oral tablet 4.5 mg.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Intravesical treatment.

**DOSE:** 5 mg/kg IV q8h; 2 mg/kg dose PO q3–24h (max. 6 mg/kg/dose).

**ACTIONS:** Antiviral.

**CI:** Hypocalcemia, ↑ K+.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic; ↓ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

GENERIC)  

**USES:** Prevention: intravitreal implant.

**DOSE:** 4.5 mg.

**ACTIONS:** Loop diuretic.

**CI:** Hypovolemia, diuretics; ↑ Na & Cl reabsorption in ascending loop of Henle & distal tubule.

**DISP:** Tablets 20, 40, 80 mg; solns 10 mg/mL.

HYDROCHLOROTHIAZIDE/AMILORIDE (MODURETIC, GENERIC)

W/P: (D, +) Idiosyncratic reaction, resulting in acute transient myelopen and acute angioedema plasma; latent ID may become manifest.
CI: Asthma, sulfonamide allergy, renal insufficiency.
DISP: Tabs 25, 50, mg; caps 1.25 mg PO q4–6h Mg/mL.
SE: ↓ K+; ↓ hypercalcinemia, hyperuricinemia, ↓ Na+; sun sensitivity.
NOTES: Follow K+, may need supplementation.

HYDROCHLOROTHIAZIDE/AMILORIDE (MODURETIC, GENERIC)

USES: *HTN.

ACTIONS: Combined thiazide & K+- sparing diuretic.
DOSE: 1–2 tabs PO. W/P: (D, +). CI: Renal failure, sulfonamide allergy.
DISP: Tabs (amiloride/HCTZ) 5 mg/50 mg. SE: ↓ BP, photosensitivity, ↓ K+; ↓ Na+; ↓ hypercalcinemia, hyperlipidemia, hyperuricemia.

HYDROCHLOROTHIAZIDE/SPIRONOLACTONE (ALDACTAZIDE, GENERIC)

USES: *HTN.

ACTIONS: Thiazide & K+-sparing diuretic.
DOSE: 25–200 mg each component q4–6h. W/P: (D, +) CI: Sulfonamide allergy.

HYDROCHLOROTHIAZIDE/TRIAMTERENE (DYAZIDE, MAXZIDE, GENERIC)

USES: *HTN.

ACTIONS: Combo thiazide & K+-sparing diuretic.
DOSE: Dyazide 1–2 caps PO daily–BID. Maxzide: 1 tab PO. W/P: (D, +). CI: Sulfonamide allergy.
DISP: Tabs (HCTZ/triamterene) 37.5/25, 75/50 mg. SE: Photosensitivity, ↓ BP, ↑ ↓ ↓ ↓ Na+, hypercalcinemia, hyperlipidemia, hyperuricemia.
NOTES: HCTZ component in Maxzide more bioavailable than in Dyazide.

HYDROCODONE (ZONEHYDRO ER)

WARNING: Addiction, abuse, misuse, overdose and death risk. Fatal respiratory depression: overdose especially in children can be fatal. With pregnancy maternal opioid withdrawal syndrome possible. Do not consume alcohol.
USES: *Pain severe enough to require daily, around-the-clock, long-term opioid.

HYDROCODONE/ACETAMINOPHEN (HYCET, LORCET, GENERIC) [C-III]

WARNING: Acetaminophen has been associated with acute liver failure (liver transplant and death possible). Most cases associated with doses ≥4,000 mg/d and often involve more than 1 acetaminophen-containing product.
USES: *Mod–severe pain.
ACTIONS: Narcotic analgesic w/ nonnarcotic analgesic.
DOSE: Adults: 1–2 caps or tabs PO q4–6h PRN. W/P: (C, M). SE: CNS depression, severe resp depression. Disp: Many formulations; specify hydrocodone/acetaminophen dose; caps 5/50 mg, tabs 2, 5/50, 5/100, 5/200, 7.5/100, 7.5/250, 7.5/500, 7.5/1000, 10/250, 10/325, 10/500, 10/650, 10/900, 10/1500, 10/1700 mg. SE: GI upset, sedation, fatigue. NOTES: Do not exceed 4–5 acetaminophen; see Acetaminophen note.

HYDROCODONE/IBUPROFEN (REPREXAN, VICOPROFEN, GENERIC) [C-III]

USES: *Mod–severe pain (≤10 days).
ACTIONS: Narcotic, w/ NSAID.
DOSE: 1–2 tabs q4–6h PRN. W/P: (C, M) renal insufficiency, ↓ effect w/ ACE inhibitors & diuretics; ↑ effect w/ CNS depressants, EDDH, MAOI, ASA, tricyclic antidepressants, anticoagulants. CI: Component sensitivity.
DISP: Tabs 2.5/7.5, 5/10 mg hydrocodone/ibuprofen.

SE: Sedation, fatigue, GI upset.
NOTES: Not for arthritis.

HYDROCORTISONE, RECTAL (ANISOL-UC SUPOSITORY, CORTIFOMO RECTAL, PROCTOCORT, OTHERS, GENERIC)

USES: *Thermal annecia conditions, radiation proctitis, dermatoic. CI:

ACTIONS: Anti-inflammatory, steroid.
DISP: Hydrocortisone acetate. Rectal aerosol 90 mg/applicator; supp 25 mg. Hydrocortisone base. Rectal 0.5%, 1%, 2.5%, rectal sup 100 mg/BY mL. SE: Minimal systemic effect.

HYDROCORTISONE, SYSTEMIC (CORTEF, SOLU-CORTEF, GENERIC) [C-II]

See also Steroids Systemic and Topical.
USE: Adrenal insufficiency.
ACTIONS: Glucocorticoid.
DOSE: 2 mg/kg IV/ID weekly; max. dose 100 mg. W/P: (B, +). CI: Viral, fungal, or tubercular skin lesions; serious infections (except septic shock or TB meningitis).
SE: Systemic: ↑ Appetite, insomnia, hyperglycemia, bruising.
NOTES: May cause hypothalamic-pituitary-adrenal axis suppression.

HYDROMORPHONE (DILAUDID, DILAUDID HP, GENERIC) [C-II]

WARNING: A potent Schedule II opioid agonist, highest potential for abuse and risk of resp depression. HP formula is highly concentrated; do not confuse w/ standard formulations; OD and death could result. Alcohol, other opioids, CNS depressants ↓ resp depression effects.
USES: *Mod–severe pain.
ACTIONS: Narcotic analgesic. DOSE: 1–4 mg PO, IM, IV or PR q4–6h PRN; max PR q4–6h PRN; w/ hepatic failure.
W/P: (B) if prolonged use or high doses near term, ↑ resp depression and CNS effects. CI: CNS leuko w/ ↑ ICP, CO2, cor pulmonale, emphyema, hydrocortisone, status asthmaticus, HP-mg form in OB anaesthesia.
DISP: Tabs 2, 4, 8 mg scored; 20 mg 5 mL or 1 mg/mL; by 1, 4 mg, Oral/Ap/10 mg/mL; sup 3 mg.
SE: Sedation, nausea, GI upset.
NOTES: Morphine 10 mg IM = Hydromorphone 1.5 mg IV.

948
**HYDROXYZINE (ATARAX, VISTARIL, GENERIC)**

**USES:** Anxiety, sedation, itching.

**ACTIONS:** Anticholinergic, antihistamine.

**DOSE:**
- Adults: 10–25 mg PO q8h;
- SE, heat prostration w/ hot weather.

**W/P:**
- 

**CI:**
- Nephrogenic.

**DISP:** Tablets 10, 25, 50 mg; sup 10 mg/g (inj 100 mg/mL).

**ACTIONS:** Anticholinergic, antispasmodic.

**USES:** Irritable bowel, spastic colitis, peptic ulcer ulcers.

**NOTES:**
- After 3–5 yr.
- 15–30 s q3mo; w/ low risk for fracture, consider D/C day (do not lie down for 60 min after); 3 mg IV over 30 min q6h.

**DOSE:**
- 

**CI:**
- Nephrogenic.

**DISP:** Tablets 100, 200, 400, 600, 800 mg; chew tabs 250, 500 mg; sup 250, 500 mg/mL; inj 200 mg/mL.

**ACTIONS:** Bactericidal; d/t susceptible bacteria.

**USES:** Lower respiratory, UTI, intra-abdominal, gen, saphenous, bone and joint, skin and skin structure, endocarditis, polymicrobial infections.

**NOTES:**
- D after 30 wk, D after 30 wk, ?/↓.

**DOSE:**
- 

**CI:**
- Nephrogenic.

**DISP:** Tablets 100, 200, 400, 600, 800 mg; chew tabs 250, 500 mg; sup 250, 500 mg/mL; inj 200 mg/mL.

**ACTIONS:** Anticholinergic, antispasmodic.

**USES:** Irritable bowel, spastic colitis, peptic ulcer ulcers.

**NOTES:**
- After 3–5 yr.
- 15–30 s q3mo; w/ low risk for fracture, consider D/C day (do not lie down for 60 min after); 3 mg IV over 30 min q6h.

**DOSE:**
- 

**CI:**
- Nephrogenic.

**DISP:** Tablets 100, 200, 400, 600, 800 mg; chew tabs 250, 500 mg; sup 250, 500 mg/mL; inj 200 mg/mL.

**ACTIONS:** Bactericidal; d/t susceptible bacteria.

**USES:** Lower respiratory, UTI, intra-abdominal, gen, saphenous, bone and joint, skin and skin structure, endocarditis, polymicrobial infections.

**NOTES:**
- D after 30 wk, D after 30 wk, ?/↓.

**DOSE:**
- 

**CI:**
- Nephrogenic.

**DISP:** Tablets 100, 200, 400, 600, 800 mg; chew tabs 250, 500 mg; sup 250, 500 mg/mL; inj 200 mg/mL.

**ACTIONS:** Bactericidal; d/t susceptible bacteria.

**USES:** Lower respiratory, UTI, intra-abdominal, gen, saphenous, bone and joint, skin and skin structure, endocarditis, polymicrobial infections.

**NOTES:**
- D after 30 wk, D after 30 wk, ?/↓.

**DOSE:**
- 

**CI:**
- Nephrogenic.

**DISP:** Tablets 100, 200, 400, 600, 800 mg; chew tabs 250, 500 mg; sup 250, 500 mg/mL; inj 200 mg/mL.

**ACTIONS:** Bactericidal; d/t susceptible bacteria.

**USES:** Lower respiratory, UTI, intra-abdominal, gen, saphenous, bone and joint, skin and skin structure, endocarditis, polymicrobial infections.

**NOTES:**
- D after 30 wk, D after 30 wk, ?/↓.

**DOSE:**
- 

**CI:**
- Nephrogenic.

**DISP:** Tablets 100, 200, 400, 600, 800 mg; chew tabs 250, 500 mg; sup 250, 500 mg/mL; inj 200 mg/mL.

**ACTIONS:** Bactericidal; d/t susceptible bacteria.

**USES:** Lower respiratory, UTI, intra-abdominal, gen, saphenous, bone and joint, skin and skin structure, endocarditis, polymicrobial infections.

**NOTES:**
- D after 30 wk, D after 30 wk, ?/↓.
DOSE:
Adults: Hospitalized: Initial 100 mg/24 h PO in 4 doses; 
Max: 500 mg/24 h max. 
Pediatrics: See adult dosages. 
PTM: (Aldara): 5% (250-mg cream) single-dose packets 5% (250-mg cream). 

INDIGO CARMINE, INJECTION (INDIGOTINDISULFONATE) (GENERIC) 
ACTION: IC: Extracted and appears in urine as blue color usually within 10 min of injection. 
DOSE: 1 ml (prefered) or IV. 
PTM: [C, 1]. 
Cl: Allergy to compound. 
DOS: 1 mg/kg max. for injection; do not dilute or inject with other solutions. 
PTM: Pseudocyesis, rarely idiopathic reaction. 
NOTE: May transiently alter pulse oximetry; originally used as a renal function test. Label is not officially approved by the FDA. 

IMIDOMETHICIN (INDOCIN, TIVOREX, GENERIC) 
WARNING: May risk of CV events & GI bleeding; not post-CABG pain. 
USES: "Arthritis (osteo, rheumatoid); ankylosing spondylitis; close ductus arteriosus, *" 
ACTION: [J] Prostaglandins. 
Adults: 25–50 mg PO BID–TID. 
Pediatrics: 0.2–0.25 mg/kg/24 h; may ingest 1–2 mg/d. 
PTM: [C +]. 
Cl: ASA/NSAID sensitivity, peptic ulcerativeGI bleed. 

INTERFERON ALFA-2B (INTRON-A) 
WARNING: Can cause or aggravate or fatal disease, myocarditis, or other serious disorder. 
USES: Primary: 
Adults: Per protocols. 
Pediatrics: Per protocols. 
DOSE: 1 mg/vial; caps 25, 50; susp 25 mg/5 mL; vials 20, 40 mg caps. 
PTM: [J] bleeding or ulcer, dizziness, edema. 
Cl: Monitor renal function. 

ISONIAZID (INH) 
WARNING: Severe and sometimes fatal hep may occur usually within 1–2 mo of therapy, although may develop after mo of therapy. 
USES: "Neat & prophylaxis of TB. 
ACTION: Bacterial: interferes w/ mycolic acid synth, disrupts cell wall. 
DOSE: Adults: Active TB: 5 mg/kg/24 h PO or IM usually (300 mg/d) or 207: 15 mg/kg (max 1000 mg) x/wk. 
Prophylaxis: 300 mg PO xt 6–12 mo or 900 mg 2x/wk. 
Pediatrics: Active TB: 10–15 mg/kg daily PO or IM (300 mg max). 
Prophylaxis: 10 mg/kg/24 h PO; in hepatolental dysfunction. 
PTM: [C, +] Liver disease, dialysis; avoid INH. 
Cl: Acute liver disease, Hep INH hep. 

ITRACONAZOLE (ONEMEL, SORANOX, GENERIC) 
WARNING: GI side effects, pruritis, palmar, xerosis, dermatitis, or scleatorrhematitis. 
USES: "Systemic antifungal used in fungal infections (aspergillosis, blastomycosis, histoplasmosis, candidiasis, onychomycosis, or " 
ACTION: Acute antifungal, J. ergosterol synth. 
DOSE: Dose based on indication. 200 mg PO daily, 150 mg 3 doses for intramuscular use. 200 mg orally, 8–12 h and 600 mg (40 mg/kg) 3 doses for intramuscular use. 
PTM: [C, +] Hypersensitivity, pruritis, xerosis, dermatitis, onychomycosis, or " 

IRBSERANT (AVAPRO) 
WARNING: D/C immediately if hypertension develops. 
USES: "HTN, diabetic nephropathy*, CHF 
ACTION: Angiotensin II receptor antagonist. 
DOSE: 150 mg PO, may tit to 300 mg. 
PTM: [C 11b, 24d, 1; J 1, 2; K, 1]. 

ISOTONIC solutions (Lactated Ringers, PlasmaLyte, Saline) 
Uses: "Surgical infections (periapical, blastomycosis, histoplasmosis, candidiasis, onychomycosis, or " 
ACTION: Acute antifungal, J. ergosterol synth. 
DOSE: Dose based on indication. 200 mg PO daily, 150 mg for oral diazepam, 1875 mg (40 mg/kg) 3 doses for intramuscular use. 
PTM: [C, +] Hypersensitivity, pruritis, xerosis, dermatitis, onychomycosis, or " 

ISSUES: "Hep, peripheral neuropathy, GI upset, anorexia, dizziness, skin reaction. 
NOTE: Use w–2–3 other drugs for active TB, based on INH resistance patterns when TB acquired & sensitivity results; prophylaxis usually w/INH alone. IM rarely used. 
Cl: Peripheral neuropathy w/ pyridoxine 50–100 mg. 
See CDC guidelines (http://www.cdc.gov/ty/ for current TB recommendations. 

ITALIAN HERBS (LAUREL, BAY, MARJORAM, OREGANO) 
USING: "Spices, flavor, condiments. 
PTM: [C, +] Hypersensitivity, pruritis, xerosis, dermatitis, onychomycosis, or " 

ITALIAN WALNUT (JUGLANS REGIA) (GENERIC) 
USING: "Walnuts, an excellent source of protein and zinc. 
PTM: [C, +] Hypersensitivity, pruritis, xerosis, dermatitis, onychomycosis, or " 

ITALIAN YARROW (AUSTRIACUM) (GENERIC) 
USING: "An edible herb, used in the treatment of digestive disorders and as a diuretic. 
PTM: [C, +] Hypersensitivity, pruritis, xerosis, dermatitis, onychomycosis, or "
KETOCONAZOLE, ORAL (NIZORAL, GENERIC)
WARNING: (Oral use) Risk of total hepatoctye. Concomitant deliabetes, deont, pricline, ciapride, metabolites, DPD and DMD, DMD and maltose, antacid production. USES: - Systemic fungal infections (Candida, dimethicone, itraconazol, etc.), refractory topical dermatophytes, infection; P:ca when rapid, testosterone needed or hormone refractory. Cushings disease medical therapy when surgery not possible. ACTIONS: Adult, a fungal cell wall synth; high dose boosts P450, too, testosterone production. DOSE: PO: 200 mg PO daily, 1 to 400 mg PO daily for serious infection. PO: 400 mg PO TID w/ hydrocortisone 20–40 mg divided BID; best on empty stomach. W/P: [C, I], io any agent that a gastric pH (absorption), may enhance antacids; an EIN (Bisulfate-like reaction); numerous interactions including statins, niacin; do not use w/ hypophosphatemia. NSAIDs may cause insufficiency, bleeding diathesis, L&D, nursing, and w/ mod–severe acute pain; CI w/ PUD, GI bleed, post surgery/L&D, w/ Hx allergy to other NSAIDs recent or of GI block or perfusion. DISP: Oral tablets 200 mg. SE: N. nausea, hair loss, headache, t PS gain, dizziness, delirium, fatigue, impotence, hepatitis, adrenal suppression, acquired cutaneous adherence ("sticky skin syndrome"). NOTES: Monitor LFTs; can rapidly ↓ testosterone levels at high dose.

KETOROLAC NASAL (SPIRX)
WARNING: For short-term (≤5 days) use; CI w/ PUD, GI bleed, suspended bleeding risk, postop CABS, advanced renal disease or risk of renal failure w/ vol depletion, risk CV thrombotic events (MI, stroke). Not indicated for use in children. USES: - Short-term (≤5 days) treat pain requiring opioid level analgesia. ACTIONS: NSAIDs, i postpartum. DOSE: - 65 yr: 31.5 mg (one 17.5 mg spray each q6h), max. 126 mg/d; ↓ 65 yr, w/ renal impairment or ↓ < 50 kg: 15.75 mg (one 17.5 mg spray in only 1 nostril) q6h, max. 63 mg/d. W/P: [C (D 3rd tri), I] do not use w/ other NSAIDs can cause severe skin reactions; do not use w/ critical bleeding risk, w/ CHF. CI: See "Warning" (prophylactic to major surgery), CI w/ allergy to other NSAIDs recent or of GI block or perfusion. DISP: Nasal spray 15.75–mg ketorolac/100 μl spray (8 sprays/bottle). SE: Nasal desensitization, t sneezing, throat irritation, oliguria, rash, ↑ AR, ↑ urine output. ↓ ↑ ALT/AST, ↑ TP. NOTES: Discard open bottle after 2 hr.

KUNECATECHINS (SINECATECHINS) (VEREGEN)
USES: - External gentianviolet warts. ACTIONS: Unknown; green tea extract. DOSE: Apply 0.5%-cm ribbon to each wart 3 x/d until all warts clear, not > 16 wk. W/P: [C, I], ↓ Dose Clear 15%. SE: Erythema, pruritus, burning, pain, lesion/crateration, edema, induction, rash, phlebitis. NOTES: Youth hands beforehand use, not necessary to scale off prior to next user, avoid on open wounds, may weaken condoms & Vag diaphragms, use in comb is not recommended.

LACTOBACILLUS (LACTINEX GRANULINES) (OTC)
USES: - Control of diarrhea, especially after antibiotic treat. ACTIONS: Repairs normal intestinal flora, lactase production, (Lactobacillus acidophilus) and Lactobacillus helveticus. DOSE: Adults: [C] or Pediatric (≤10 yr), 1 packet, 1–2 caps, or 4 to 6 tabs PO–QD. W/P: [C, I]; ↓ Some products may contain whey. CI: Milk/lactose allergy. DISP: Tabs, caps, granules in packets (all OTC). SE: Flatulence, Dyspepsia. NOTES: May take granules on food.

LANTHANUM CARBONATE (FOSFENOL)
USES: - Hyperphosphatemia in end-stage renal disease. ACTIONS: Phosphate binders. DOSE: 750–1,500 mg PO daily in —, obese, w/ or immediately after meal; (tablete I) – I I-bound on PO, levels. W/P: [C, I] — No data in GI disease, not for peds. CI: Bowel obstruction, fecal impaction, ileus. DISP: Chew tabs 500, 750, 1,000 mg. SE: ↑ Gastro occlusion, headache, ↑ TP. NOTES: Chew tabs before swallowing, separate from meds that interact w/ antibiotics by 2 hr.

LEUPROLIDE (ELIGARD, LUPRON, LUPRON DEPOT, LUPRON DEPOT-PED, GENERIC)
USES: - Advanced PCA (all except Depot-Ped), endometriosis (Lupron), urethral fibrosis (Lupron), & precocious puberty (Lupron-Ped). ACTIONS: LHRH agonist, paradoxically, release of GnRH w/ Gn from anterior pituitary; in men ↓ testosterone, in women ↓ estrogen. DOSE: Adults: PCA: LUPRON DEPOT: 7.5 mg IM q4wk or 22.5 mg IM q8w or 45 mg IM q4mo. Eligard: 7.5 mg SQ q4wk or 22.5 mg SQ q6w or 45 mg SQ q2mo or 45 mg SQ q1mo. Endometriosis (LUPRON DEPOT): 3.5 mg IM q4w × 1 or 21.5 mg q2w × 1. Lupron for PCa: 25–35.75 mg IM q4wk; ↓ 37.5 mg IM q8w; ↓ 30 mg IM q4mo; ↓ 57.5 mg IM q2mo; ↓ 57.5 mg IM q1mo. Lupron-Ped: 50 μg/kg SQ q4wk; ↓ 10 μg/kg until annual downregulation achieved. Lupron DEPOT: 25 mg 3.75 mg IM q4wk. W/P: [K, I] ↓ Impending cord compression in PCA, I ↓ w/ meds or pre-existing CV disease; postmarketing reports of seizures. CI: AUB, implant in nonmen/peds, pregnancy. DISP: Inj 5 mg/mlmL, LUPRON DEPOT: 7.35 mg 1 mL for fibrinol, endometriosis; LUPRON DEPOT for PCa: 7.35 mg (1 mL), 11.25 (3 mL), 22.5 (10 mL), 45 mg (14 mL), 45 mg (16 mL). Eligard depot for PCA: 7.5 mg (1 mL), 22.5 (3 mL), 30 (4 mL), 45 mg (6 mL), LUPRON DEPOT-Ped: 7.5, 11.25, 15, 30 mg. SE: Hot flashes, gynecomasia, NV, diplopia, anorexia, dizziness, headache, insomnia, panthothenics, depression, depression, peripheral edema, & bone pain (transient "false reaction" 7–14 days after the 1st dose/3[hypercalcemia supress before suspension]); ↓ BMI w/ ≤ 8–6–8–6 use, bone loss possible, abnormal bone density, hypercalcemia. NOTES: Nonsteroidal antiinflammatory (Ig, bicarbamid) may block function in men w/ PCa, Viadur 12 mo form unavailable to new patients.
**LEVOFLOXACIN (LEVAQUIN, GENERIC)**

### Uses:
- Topical anesthetic for venipuncture and dermatologic procedures.
- Local anesthetic, epidural/caudal anesthesia.
- Regional nerve blocks, topical on mucous membranes.
- Inhibits ionic fluxes required for initiation and conduction.

### Dosage:
- Adults: Inj: 200 mg/mL; tabs 250, 750 mg, Inj 1 g (amp); Pronto 2.5 g thick layer 2–2.5 g to intact skin over 20–25 cm² of skin surface; cover with occlusive dressing (eg, Tegaderm) for at least 1 hr. Peds: Max. 30 mL to dry hair, develop a lather; wash off for 4–5 min, comb-out rins.

### Side Effects:
- Erythema, blanching, and edema.
- Component sensitivity (PABA or local anesthetics).

### Notes:
- Use on skin only; avoid eyes; use sparingly.
- Apply 30 mL to dry hair, develop a lather; wash off for 4–5 min, comb-out rins.

### LIDOCAINE/P RILOCaine (EMLA, ORAq IX)

### Uses:
- Topical anesthetic for intact skin or genital mucous membranes; adjust to physeology or dermal procedures.

### Actions:
- Local anesthetics.

### Dosage:
- Adults: EMLA cream, thin layer 2–2.5 g to intact skin over 20–25 cm² of skin surface; cover with occlusive dressing (eg, Tegaderm) for at least 1 hr.
- Peds: Max. dose: 3–3 mg/kg or 5 kg: 1 g/10 cm² for 1 hr. 3–12 mo & > 5 kg: 2 g/20 cm² for 4 hr.

### Side Effects:
- Dizziness, paresthesias, & seizures associated w/ depression.

### Notes:
- Longer contact time ↑ effect.

### LIDOCAINE/TETRACAINE, PATCH (SYNERA) CREAM (PLIAGLIS)

### Uses:
- Topical anesthetic for venipuncture and dermatologic procedures (Synera). dermatologic procedures (Patchy).

### Actions:
- Combi anest and anest local anesthetic.

### Dosage:
- Adults & Peds: Synera: Apply patch 20–30 min before procedure.
- Peds: Apply cream 25–40 min before procedure, volume based on site surface (use label).

### Side Effects:
- Erythema, blanching, and edema.

### LINDANE (GENERIC)

### Warning:
- Only for proximoinferior 1st line treat for sebaceous agents.

### Uses:
- Skin irritant.

### Actions:
- Ectoparasiticide & ovicide.

### Dosage:
- Adults & Peds: Cream on lesion: Thin layer to dry skin after curing, leave for 8–12 hr; may also use on laundry. Shampoo: Apply 30 mL to dry hair, develop a lather; wash off for 4–5 min, comb-out rins.

### Side Effects:
- Erythema, blanching, and edema.
W/P: [C (troleandomycin)]

**LYMPHOCYTE IMMUNE GLOBULIN (ANTITHYMOCYTE GLOBULIN, ATG) (ATGAM)**

**WARNING:** Should only be used by physician experienced in immunosuppressive therapy or management of solid organ and/or BMT pts. Adequate lab and supportive resources must be readily available.

**USES:** Anti-thymocyte globulin if not candidates for BMT.

**DISP:**
- **Premix Inj:** 10, 20, 40, 80 mg/mL; Inj 125, 250, 500, 600 mg; tabs 400 mg (OTC).
- **Cream:** 1%; 30/60 g.

**SE:** Anaphylactoid reaction (rare), dizziness, headache, edema, skin rash.

**W/P:**
- **GI:** abdominal pain, vomiting, diarrhea, anorexia, cramps, constipation, nausea, ileus.
- **Respiratory:** wheezing, bronchospasm, dyspnea.
- **Skin:** rash, pruritus, urticaria.
- **Other:** fever, chills, myalgia, systemic reaction precludes use; give via central line; site reaction, rare.

**NOTES:**
- **INJECTABLE** (Genentech, San Francisco, CA).
- **Ophthalmic** (Alcon Laboratories, Fort Worth, TX).
- **Rheumatic** (Mepha, Neuss, Germany).
- **Transplant** (Lilly).
MEGESTOL ACETATE (MEGACE, MEGACE-ES)

USES: “Anorexia, cachexia, or an unexplained significant weight loss in patients with AIDS; palliative treatment of advanced carcinoma of the breast or anovulatory." 

ACTIONS: Hormone; anti-lueticizing; progestogenic analog.

DOSE: 40–320 mg/d divided doses.

NOTES: Do not D/C abruptly; Megace-ES not equivalent to others in mg.

W/P: [C, –] risk for dependency, j seizure threshold, adrenal insufficiency, head injury. 1 ICP, hepatic impairment, not OK in sickle cell disease.

CI: no MADDs.

DISP: Tabs 50, 100 mg; intracut 50 mg/mL; inj 25, 50, 75, 100 mg/mL.

SE: Rare CNS depression, seizures, adenocarcinoma; j BP; rash; N/V; bilirubin and urea spures, dyspnea.

NOTES: None.

MEPHALAN (L-PAM) (ALKERAN, GENERIC)

WARNING: Administer under the supervision of a qualified physician experienced in the use of chemotherapy. Multiple myeloma and mantle cancer*, breast & testicular cancer, melanoma; allergic & ABMT (high dose), neutropenia, thrombocytopenia.

ACTIONS: Ablating agent, nitrogen mustards.

DOSE: Alkylating multiple myeloma: 16 mg/m² IV qIVq: 4 d then at 4-wk intervals after tumor reduces; w/ or without pred. j BP, j RR allergic reaction, rash, j Ca, j glucose, j protein, j Mg, ethanol, hyoscines, j BM, j FP CT, palpitations.

NOTES: Do not D/C abruptly; Mephalan ES not equivalent to others in mg.

Peds: 2 mg/m² IV qIVq.

W/P: [D, –] r rigors from amphotericin B.

NOTES:

MEGETROL ACETATE (MEGACE, MEGACE-ES)

USES: “Anorexia, cachexia, or an unexplained significant weight loss in patients with AIDS; palliative treatment of advanced carcinoma of the breast or anovulatory." 

ACTIONS: Hormone; anti-lueticizing; progestogenic analog.

DOSE: Apertan. Megestrol ES 825 mg/dly (35 mL or 1 teaspoon), breast cancer: 160 mg/dQD (40 mg QOD), Endometrial cancer: 40–130 mg/dly divided doses.

Peds: 1–15 mg/kg/day PO in 2–4 divided doses.

W/P: [D, –] r thromboembolitis; handle w/ care.

CI: Pregnancy.

DISP: Tabs 20, 40, 45 mg; inj 50 mg/mL, Megestrol ES 135 mg/mL.

SE: Ovarian, breast, hepatic, intestinal bleeding, photosensitivity, N/V diarrhea, headache, mastodynia, j Ca, j glucose, j protein.

MELPHALAN (L-PAM) (ALKERAN, GENERIC)

WARNING: Administer under the supervision of a qualified physician experienced in the use of chemotherapy. Multiple myeloma and mantle cancer*, breast & testicular cancer, melanoma; allergic & ABMT (high dose), neutropenia, thrombocytopenia.

ACTIONS: Ablating agent, nitrogen mustards.

DOSE: Alkylating multiple myeloma: 16 mg/m² IV qIVq: 4 d then at 4-wk intervals after tumor reduces; w/ or without pred. j BP, j RR allergic reaction, rash, j Ca, j glucose, j protein, j Mg, ethanol, hyoscines, j BM, j FP CT, palpitations.

NOTES: Do not D/C abruptly; Mephalan ES not equivalent to others in mg.

Peds: 2 mg/m² IV qIVq.

W/P: [D, –] r rigors from amphotericin B.

NOTES:

MEGETROL ACETATE (MEGACE, MEGACE-ES)

USES: “Anorexia, cachexia, or an unexplained significant weight loss in patients with AIDS; palliative treatment of advanced carcinoma of the breast or anovulatory." 

ACTIONS: Hormone; anti-lueticizing; progestogenic analog.

DOSE: Apertan. Megestrol ES 825 mg/dly (35 mL or 1 teaspoon), breast cancer: 160 mg/dQD (40 mg QOD), Endometrial cancer: 40–130 mg/dly divided doses.

Peds: 1–15 mg/kg/day PO in 2–4 divided doses.

W/P: [D, –] r thromboembolitis; handle w/ care.

CI: Pregnancy.

DISP: Tabs 20, 40, 45 mg; inj 50 mg/mL, Megestrol ES 135 mg/mL.

SE: Ovarian, breast, hepatic, intestinal bleeding, photosensitivity, N/V diarrhea, headache, mastodynia, j Ca, j glucose, j protein.

MELPHALAN (L-PAM) (ALKERAN, GENERIC)

WARNING: Administer under the supervision of a qualified physician experienced in the use of chemotherapy. Multiple myeloma and mantle cancer*, breast & testicular cancer, melanoma; allergic & ABMT (high dose), neutropenia, thrombocytopenia.

W/P: [D, –] r rigors from amphotericin B.

NOTES:
METRONIDAZOLE (FLAGYL, FLAGYL ER, METOCREEM, METROGEL, METROLATION)

WARNING: Carcinogenic in rats.

USES: Metronidazole: flagelate (Trichomonas vaginalis, anaerobic bacteria, Helicobacter pylori), protozoa (Giardia lamblia), Trichomonas vaginalis, Giardia lamblia, anaerobic bacteria, especially in infections such as peptic ulcer disease, intra-abdominal infections, pelvic inflammatory disease, and intrauterine device infections. Metronidazole is a nitroimidazole derivative that inhibits bacterial and protozoal DNA synthesis by acting as a DNA alkylating agent. It is active against a wide range of aerobic and anaerobic bacteria and protozoa.

DOSE: Adults: 2 g/d; PO: 300 mg PO q4h or 500 mg PO q8h or 750 mg PO q12h for 7–10 days (PO preferred); IV: only if oral is not possible. IV: 1–2 mg/kg/dose IV as adults. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults & Peds: >14 yr: intravenous: 10 mg IV 1 over 1–2 min. Peds: Repeat: 1–2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults: 2 g/d; PO: 300 mg PO q4h or 500 mg PO q8h or 750 mg PO q12h for 7–10 days (PO preferred); IV: only if oral is not possible. IV: 1–2 mg/kg/dose IV as adults. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

METHYLENE BLUE (UROLENE, GENERIC)

DOSE: Adults: 2 g/d; PO: 300 mg PO q4h or 500 mg PO q8h or 750 mg PO q12h for 7–10 days (PO preferred); IV: only if oral is not possible. IV: 1–2 mg/kg/dose IV as adults. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults & Peds: >14 yr: intravenous: 10 mg IV 1 over 1–2 min. Peds: Repeat: 1–2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults & Peds: >14 yr: intravenous: 10 mg IV 1 over 1–2 min. Peds: Repeat: 1–2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults & Peds: >14 yr: intravenous: 10 mg IV 1 over 1–2 min. Peds: Repeat: 1–2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults & Peds: >14 yr: intravenous: 10 mg IV 1 over 1–2 min. Peds: Repeat: 1–2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults & Peds: >14 yr: intravenous: 10 mg IV 1 over 1–2 min. Peds: Repeat: 1–2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.

WARNING: CHLORAMPHENICOL (METAZOLV, REGLAN, GENERIC)

DOSE: Adults & Peds: >14 yr: intravenous: 10 mg IV 1 over 1–2 min. Peds: Repeat: 1–2 mg/kg/dose PO 30 min ac & hs. Chemo antiemetic: 1–2 mg/kg/dose IV as adults. Adults: 0.25 mg PO q4–8 h. Pediatric: 0.1–0.2 mg/kg/dose PO 30 min ac & hs.
MICAFUNGIN (MYCAMINE)

**USES:** Candidemia, acute disseminated candidiasis, Candida peritonitis & abscesses; prophylaxis Candida infection w/ HCT.

**ACTIONS:** Echinocandin, fungal cell wall synth.

**DOSE:** A. Con: 15–45 mg PO PRN. Fecal inspection after barium: 118 mL rectally × 1.

**WARNING:** Do not crush/ chew. keep away from children, throat dissection in < 1 yr or use last half of pill.

**MICONAZOLE (MONISTAT 1 COMBO, MONISTAT 3, MONISTAT 7 (OTC))

**USES:** Candital infections, dermatomycoses (tinea pedis/tinea cruris/candidiasis).

**ACTIONS:** Local antifungal, alters fungal membrane permeability.

**DOSE:** 150 mg IV daily; ↓ dosage adj may be necessary.

**SE:** Sepsis, Clostridium difficile, colitis, cholestasis, shock, hypotension.

**MICONAZOLE/ZINC OXIDE/PETROLATUM (TUCKS MINERAL OIL [OTC])

**USES:** Acute burning; on skin contact dermatitis, irritation, hydrate well.

**ACTIONS:** Temporary relief of anorectal disorders (first 7 days).

**DOSE:** Apply at each diaper change (2–12 yr); 50–60 mg/m2, N/V, diarrhea, headache, fever, rash, joint pain, fatigue, distension, photosensitivity, hyperpigmentation, 5L syndrome, pseudomembranous colitis.

**NOTES:** Do not cut/throw, keep away from children, tooth discoloration in <1 yr or use last half of pill.

**MINERAL OIL (OTC)

**USES:** Constipation, bowel irritation, fecal impaction.

**ACTIONS:** Lubricant laxative.

**DOSE:** Adults: 15–45 mL PO PRN. Fecal inspection after barium: 118 mL rectally × 1.

**WARNING:** Do not use PO in peds < 1 yr; do not use PO in peds > 1 yr.

**SE:** Lipid pneumonia (aspiration of PO mineral oil), ↑ protein, ↑ lipid phospholipids.

**MINERAL OIL/PRAMOXINE HCL/ZINC OXIDE (TUCKS OINTMENT (OTC))

**USES:** First 7 days.

**ACTIONS:** Topical anesthetic.

**DOSE:** Adults & Peds: ≥ 12 yr: Cleanse, rinse, & dry, apply externally or into anus canal w/ tip 3 × /12 h.

**SE:** No placement into rectum.

**MITOMYCIN (GENERIC)

**ACTIONS:** Alkylating agent; generates oxygen-free radicals,↑ protein synthesis.

**DOSE:** 1.7 mg/dL/↓ serum digoxin when starting both together.

**SE:** Colitis, vomiting, nausea, diarrhea, bloody diarrhea, anorexia, dizziness, fatigue.

**MIRABEGRON (MYRBETRIQ)

**USES:** Overactive bladder (OAB) w/ symptoms of urge urinary incontinence, urgency, and urinary frequency.

**ACTIONS:** 0–3 adrenergic agonist; relaxes smooth muscle.

**DOSE:** Start 25 mg PO daily; ↑ to 50 mg daily after 8 wk. PRN: 25 mg. daily w/ severe renal or mild hepatic impairment; swallow whole, do not cut/chew.

**SE:** [D, –] Severe uncontrolled HTN, urinary retention w/ bladder outlet obstruction & antimuscarinic drugs; w/ drugs metabolized by CYP2D6 (e.g., thioridazine, flecainide, propafenone); do not use w/ ESRD or severe hepatic impairment; monitor serum digoxin when starting both together.

**MITOMYCIN (GENERIC)

**ACTIONS:** Alkylating agent, generates oxygen-free radicals,↑ protein synthesis.

**DOSE:** 1.7 mg/dL/↑ protein synthesis.

**SE:** Colitis, vomiting, nausea, diarrhea, bloody diarrhea, anorexia, dizziness, fatigue.

**MIRABEGRON (MYRBETRIQ)

**USES:** Overactive bladder (OAB) w/ symptoms of urge urinary incontinence, urgency, and urinary frequency.

**ACTIONS:** 0–3 adrenergic agonist; relaxes smooth muscle.

**DOSE:** Start 25 mg PO daily; ↑ to 50 mg daily after 8 wk. PRN: 25 mg. daily w/ severe renal or mild hepatic impairment; swallow whole, do not cut/chew.

**SE:** [D, –] Severe uncontrolled HTN, urinary retention w/ bladder outlet obstruction & antimuscarinic drugs; w/ drugs metabolized by CYP2D6 (e.g., thioridazine, flecainide, propafenone); do not use w/ ESRD or severe hepatic impairment; monitor serum digoxin when starting both together.

**MITOMYCIN (GENERIC)

**ACTIONS:** Alkylating agent; generates oxygen-free radicals,↑ protein synthesis.

**DOSE:** 1.7 mg/dL/↑ protein synthesis.

**SE:** Colitis, vomiting, nausea, diarrhea, bloody diarrhea, anorexia, dizziness, fatigue.
**MITOTANE (LYSODREN)**

**WARNING:** Administer only by physician experienced in chemotherapy, discontinue temporarily immediately following shock or severe trauma since adrenal suppression is its prime action. Exogenous steroids should be administered in such circumstances.

**USES:** Adjuvant chemotherapeutic agent, suppresses corticosteroid production by inhibiting 11β-Hydroxylase (aromatase OC).

**DOSE:** 2–6 g/d in divided dose TID–QID; increase as tolerated up to max. tolerated dose (generally 2–10 g/d); decrease dose with side effects; administer with glucocorticoids and if needed mineralocorticoid replacement.

**W/P:** [C, I]; increases warfarin metabolism.

**CI:** Hypersensitivity to compound.

**DISP:** Tablets 500 mg.

**SE:** Adrenal insufficiency, GI distress, depression, lethargy, somnolence, dizziness, vertigo, orthostasis.

**NOTES:** Neurapraxic testing with use ≥2 yr; higher doses of glucocorticoids required due to metabolism; treat until there is no clinical benefit.

**MITOXANTRONE (GENERIC)**

**WARNING:** Administer only by physician experienced in chemotherapy, except for acute leukemia, do not use in WBC count of <1,500 cells/mm<sup>3</sup>; severe neutropenia can result in infection, follow CBC; cardiotoxic (CHF); secondary analysis, ARB recommended.

**USES:** Combination for myelogenous, promyelocytic, monocytic, and erythroid acute leukemias, progressive relapsing MS; pain related to inoperable adrenocortical carcinoma; discontinue temporarily in LVEF .

**ACTIONS:** Anthracycline; DNA-intercalating agent; pDNA synth by attacking topoisomerase II.

**DOSE:** IV prop, Cap 12–14 mg/kg ext 3–5 mg PO BID; ↓ dose w/ hepatic impairment, leukopenia, thrombocytopenia.

**W/P:** [B, D–I]; reports of secondary AML, w/ MS.

**CI:** Hypersensitivity, kidney disease, head injury; chewing delayed release forms can cause severe tissue reaction.

**SE:** Moderate to severe neutropenia, thrombocytopenia, anemia, leukopenia, GI distress, nausea, vomiting, diarrhea, abdominal pain, edema, fever, chills, headache, arthralgia, myalgia, hypotension, rash, urticaria, hypoadrenalinemia.

**NOTES:** May require chelated dosing to relieve severe tissue pain.

**MOXIFLOXACIN (AVELOX)**

**WARNING:** Risk Achilles tendon rupture and tendinitis. 1 in pts >60 yr; on steroids or with organ transplant; avoid w/ myelophthemia, may cause muscle weakness.

**USES:** Acute sinusitis & bronchitis, skin/tissue/bone/tendon/dental infections, conjunctivitis, community-acquired pneumonia 1B, anthrax, endocarditis.

**ACTIONS:** 4th-gen quinolone; pDNA synth. Spectrum: Excellent gram < except MRSA & S. aureus; good gram < except P. aeruginosa, Stenotrophomonas maltophilia, V. acnes, Enterococcus spp; good aerobic.

**DOSE:** 400 mg PO/TIV daily; avoid cation products, reduce 1B.

**W/P:** [D, C]; ↓ quinolone sensitivity, interactions w/ maj <, CYP1A2, 2C9, 3A4-containing products, & class III & IV antiarrhythmic agents.

**CI:** Quinolone component sensitivity.

**DISP:** Tablets 400 mg, ABC Pak 5 tabs, inj.

**SE:** Diarrhea, N, QT prolongation, sepsis, photosensitization, peripheral neuropathy risk.

**MUPIROCIN (BACTROBAN, BACTROBAN NASAL)**

**USES:** Impetigo (cont); skin lesion infection w/ S. aureus or S. pyogenes; eradicates NRP in nasal carriage.

**ACTIONS:** Bacterial protein synth.

**DOSE:** Topical: Apply small amount 3–5 x 5–14 days. Nasal: Apply 1/2 single-use tube BID in nostril 5–14 days.

**W/P:** [B, I, M]; do not use w/ other nasal products.

**DISP:** Oral 2%, cream: 2%; nasal unit 2% 1-g single-use tube.

**SE:** Nasal irritation, rash.

**NOTES:** Pt to contact healthcare provider if no improvement in 3–5 days.

**MYCOPHENOLATE MOFETIL (CELLCEPT, GENERIC)**

**WARNING:** Risk of infections, lymphoma, other cancer, progressive multifocal leukoencephalopathy (PML); risk of pneumonia loss and inflammation; female of child-bearing potential must use contraception.

**USES:** Prevent organ rejection after transplant.

**ACTIONS:** Cytosine to lymphocytes.

**DOSE:** Adults: 1 g PO BID, dose differ based on transplant.

**W/P:** [D, A-C]; 1 or 1.5 or 2 mg; 750 mg PO BID, [D, A-C]; 2–7.5 mg; 1 g PO used w/ steroids or prednisone or tacrolimus; ↓ in renal insufficiency in neutropenia.

**SE:** Infusion over ≥ 2 hr. PO: Take on empty stomach, do not open caps.

**DISP:** Caps 250, 500 mg; susp 200 mg/mL, inj 550 mg.

**CI:** Hypersensitivity, pain, fever, headache, infection, HTN, anemia, leukopenia, edema.

**NOTES:** CellGard & Myfico are not interchangeable.

**NALOXONE (GENERIC, EVZIO)**

**USES:** Opioid addiction (diagnosis) & OD.

**ACTIONS:** Competitive opioid antagonist.

**DOSE:** Oral: Apply small amount 3–10 x 5–14 days. Nasal: Apply 1/2 single-use tube BID in nostril 5–14 days.

**W/P:** [B, I, M]; do not use w/ other nasal products.

**DISP:** Oral 2%, cream: 2%; nasal unit 2% 1-g single-use tube.

**SE:** Nasal irritation, rash.

**NOTES:** Pt to contact healthcare provider if no improvement in 3–5 days.
**NAPROXEN (ALEVE [OTC]), ANAPROX, ANAPROX DS, EC-NAPROSYN, NAPRELAN, NAPROSYN, GENERIC**

**WARNING:** May ↑ risk of CV events & GI bleeding.

**USES:** Arthritis & pain.

**ACTIONS:** NSAID, prostaglandins.

**DOSE:** 
- Adults & Peds: > 12 yr: 200–500 mg BID to 1,500 mg/d max.
- > 2 yr: 245–510 mg/d PO, ↓ in hepatic impairment.

**W/P:** PO; ↓ in 3–4 doses.

**CI:** NSAID or ASA triad sensitivity, peptic ulcer, tox; also topical 

**Peds:** 0.01–0.1 mg/kg/dose IV, IM, or SQ; repeat IV 1–2 h ra co r2h rp c.

**SE:** Headache common on initial Treat; reflex sympathetic dystrophy; peripheral neuropathy, muscle 

**DISP:** PO soln may ↓ absorption; may ↑ with foods; GI upset; ↑ in pts with renal impairment.

**NEOMYCIN (NEO-FRADIN)

**WARNING:** Systemic absorption of oral route may cause neurotoxicity; rash; opportune infections. 

**USES:** Neutropenic colitis; ophthalmic w/ other topical agents; ear aminoglycoside; interstitial pneumonitis possible; most cases in 1st 3 mo; may require alternative CS for refractory cases.

**W/P:** PO; ↓ in 3–4 doses; 12 g max.

**DOSE:** PO: 50–100 mg/kg/d PO in 3–4 doses; 12 g max.

**CI:** Renal failure, neuromuscular disease, hoarseness, hearing loss.

**DISP:** Tabs 500 mg; Afl急Furadantin 200,000 U/mL; amp 1, 20 mL.

**NOTES:** Avoid w/ CrCl < 50 mL/min; use 400 mg qd.

**NEOMYCIN-POLYMIXYN BLADDER IRRITANT [NEOSPORIN GU IRRIGANT]

**USES:** ↓ Bladder irritant in the urinary bladder of albinistic patients to help prevent bacteria and gram-negative rod sepsis associated with the use of indwelling catheters.

**ACTIONS:** Bactericidal; do not for Senita or streptococc.

**DOSE:** 1 mL irrigant in 1 L of 0.9% NaCl; contain 640,000 U/mL; amp 1, 20 mL.

**CI:** Component allergy, anti-pseudomonal allergy.

**DISP:** Sodium neomycin sulfate 40 mg & polymyxin B 200,000 U/mL; amp 1, 20 mL.

**SE:** Rash, neomycin ophthalmic (rare).

**NOTES:** Potential for bacterial/fungal super-infection; not for IV use only 3-way catheter for irrigation.

**NIFEDIPINE (ADALAT CC, AFEITAB CR, PROCARDIA, PROCARDIA XL, GENERIC)

**USES:** HTN; tocolytic.

**ACTIONS:** Calcium channel blocker.

**DOSE:** 
- Adults: SR tabs 30–90 mg/d.
- PO: 0.25–0.5 mg/kg q24h + 0.6–4 y/d.

**W/P:** PO; ↓ in hepatic impairment.

**CI:** NSAID, aminoglycoside allergy.

**DISP:** Caps 10, 20 mg; SR tabs 30, 60, 90 mg.

**SE:** Headache common on initial Treat; reflex sympathetic dystrophy; peripheral neuropathy; ↑ BP, flushing, dizziness.

**NOTES:** Adalat CC & Procardia XL not interchangeable; used for medical expulsive therapy of ureteral stone; consider to IV w/ 1 blockers such as tamsulosin.

**NITROFURANTOIN (FURADANTIN, MACROBID, MACRODANTIN, GENERIC)

**USES:** Prophylaxis & treat UTI.

**ACTIONS:** Interferes w/ metabolism & cell wall synthesis. Spectrum: Some gram (+) & (-) Bacteria; Proteus, Enterococcus, Salmonella, & some Pseudomonas resistant.

**DOSE:** 
- Adults: Prophylaxis: 50–100 mg PO; Treat: 50–100 mg PO QID × 7 days; Macrolid 100 mg PO BID × 7 days.
- Peds: Prophylaxis: 1–2 mg/kg/d PO × 1–2 doses; max 100 mg/d. Treat: 5–7 mg/kg/d in 4–6 doses (as needed/failure).

**W/P:** PO; ↓ in OK if child < 1 mo) avoid w/ CR1 < 40 mL/min.

**CI:** Anuria, diaphoresis, or significant impairment of renal function (CrCl < 60 mL/min). Infants < 1 mo; pregnancy at term; history of cholestatic jaundice/hyperbilirubinemia associated w/ nitrofurantoin.

**DISP:** Caps 25, 50, 100 mg. Vodantoin susp 25 mg/mL.

**SE:** GI effects, depigmentation, various autonomic/pulmonary reactions, peripheral neuropathy, hemolytic anemia w/ G6PD deficiency, rare aplastic anemia.

**NOTES:** Macrolides (eg, Macrodantin) > neosporin than other forms; not for comp UTI; may turn urine brown (reflective of piperacillin or cephalosporin).

**NORFLOXACIN (NOROXIN)

**WARNING:** Risk Achilles tendon rupture and tendinitis, ~ 1 yr pts > 60 yr; on steroids or with organ transplant; avoid w/ myasthenia gravis, may ↑ muscle weakness.

**USES:** Cmp & uncomp UTI; prototaxis due to E. coli, gonorrhea, inflammatory diarrhea, conjunctivitis.

**ACTIONS:** Quinolone, J, DNA gyrase, bacteriostatic. Spectrum: Broad gram (+) and (-) E. coli, cef, k. pneumoniae, F. meningitidis, F. urethritis, S. epidermidis, S. aureus.

**DOSE:** 
- Uncomp UTI (E. coli, K. pneumoniae, P. aeruginosa): 400 mg PO BD × 3 doses; other uncomp UTI Treat: 7–10 days. Comp UTI: 400 mg PO q8h for 10–31 days. Gonorhea: 800 mg × 1 dose. Prostatitis: 400 mg PO BID × 28 days. Cysticfibrosis, traveler’s diarrhea: 400 mg PO BID × 1–3 days; take 1 h ac or 2 h pc.

**W/P:** PO; ↓ in Quinolone sensitivity, w/ some antibiotics ↓ QT.

**CI:** ↑ in left ventricular ejection fraction due to paroxysm.

**DISP:** Tabs 400 mg; ciprofloxacin 3 mg/mL.

**SE:** Phototoxicity, headache, dizziness, asthenia, GI upset, pseudomembranous colitis, ocular burning w/ ophthal., peripheral neuropathy risk w/ PO only.

**NOTES:** Interactions w/ antacids, theophylline, caffeine, good conc in the kidney & urine, poor blood levels; not for uspseps, CJD, suggests do not use for GC.
OXYBUTYNIN TRANSDERMAL SYSTEM (OXYTROL, OXYTROL FOR WOMEN [OTC])

OXYBUTYNIN (GENERIC)

USES: *Microsporum Canis infections (oral, skin, scalp).*

DOSE: Adults & Peds: PO: 400, 200–400, 600 U PO “wash & swallow” QID. Vag: 1 tab Vag hs 2 or hs, Topical: Apply BID–TID to area.

Ped Infants: 200,000 U PO q6h.

W/P: [B, ?/L, ?/O].

DISP: PO susp 100,000 U/mL; PO tabs 500,000 U; capsules 200,000 U; Vag tabs 100,000 U; topical ointment 100,000 U/g. Powder 100,000 U/g.

SE: GI upset, 5%. Not for systemic infections; see also transepidermal forms.

NFLOXACIN (FLOXIN)

WARNING: *Risk Achilles tendon rupture and tendinitis. 3 yr or pts >60 yr, on steroids or with organ transplant; avoid w/ myasthenia gravis, may ↑ weakness.

USES: *Lower resp tract, skin, skin structure, & UTI, prostatitis, uncomp mononucleosis, & Chlamydia infections.*

DOSE: Adults: 200–400 mg PO BID or tr q12h. ↓ in renal impairment, take on empty stomach.

W/P: [B, ?/L, ?/O]. Absorption w/ antacids, sucralfate, H2, CYP3A4 inhibit, CYP2C9, and CYP2C19; highly protein bound, ↑ by antacids, sucralfate, H2, CYP3A4, CYP2C9, and CYP2C19; highly protein bound, may be displaced by other highly bound drugs. Risk of CVA, QT interval, memory impairment; ER form empty shell expelled in stool.

SE: Diarrhea, headache, constipation, dizziness. NOTES: ODT contains phenylalanine. No single IV dose ≥ 8 mg.

ONDANSETRON, ORAL SOLUBLE FILM (ZUPLENZ)

USES: Prevent chemotherapy-induced & postop N/V.

ACTIONS: Serotonin receptor (5-HT3) antagonist.

DOSE: Adults: Highly emetogenic chemo: 24 mg 8 mg film 30 min prechemo; HT all IV: 8 mg film 10D. Adults & Peds: ≥ 32 yr: Mod emetogenic chemo: 8 mg film 30 min prechemo, then 8 mg in 8 hr; 8 mg film 900 mg × 1–2 days after chemo.

Adults: Postop: 1 mg 8 mg film 30 min × 2 hr preop; ↑ w/ hepatic impairment.

W/P: (B, ?/L, ?/O).

C: Apomorphine.

DISP: Oral soluble film 4, 8 mg.

SE: Use w/ dry hands, do not chew/swallow, place on tongue, dissolve in 4–20 s. peppermint flavored.

OSPEMIFENE (OSPHENA)

WARNING: *Risk endometrial Ca, ↑ risk of CVA, DVT.*

USES: *Treatment of moderate–severe dyspareunia.*

ACTIONS: Estrogen agonist/antagonist.

DOSE: Adults: 1 tab daily.

W/P: [B, ?/L, ?/O]. Do not use w/ estrogens and estrogen agonist/antagonists, fluconazole & rifampin ↑ effect, ketonazole ↓ effect. ↑ tab effects w/ drugs that inhibit CYP3A4 and CYP2D6. High protein bound, may be displaced by other highly bound drugs.

C: Estrogland glandular bleeding known/expected estrogen-sensitive cancer; pregnancy.

DISP: Tab 60 mg.

SE: DVT, hemorhorax or thrombotic stroke, arterial thromboembolism cl, hot flashes; vaginal discharge; hypoestrogenism, muscle cramps, metabolized by CYP3A, CYP2C9, and CYP1A2.

DOSE: Do not use w/ severe liver disease.

OXACILLIN (GENERIC)

USES: *Infections of susceptible S. aureus, Neisseria & other organisms.*

ACTIONS: Bactericidal, 100% wall synth. Spectrum: Excellent gram (+ –), poor gram (+ –).

DOSE: Adults: 250–500 mg (2 g severe) IV or q4–6h.

Ped: 25–300 mg/kg IV q4–6h.

W/P: [B, ?/L, ?/O].

C: FN sensitivity.

DISP: Powder for 10 500 mg, 1, 2. 10 g.

SE: GI upset, interstitial nephritis, blood dyscrasias, may ↓ DSF-effectiveness.

OXYBUTYNIN (DITROPAN, DITROPAN XL, GENERIC)

USES: Relief of symptoms of bladder instability associated with voiding in patients with unobstructed neurogenic or reflex neurogenic bladder (4x, urgency, frequency, urinary leakage, urge incontinence, dysuria). DITROPAN: Overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency; pediatric patients <6 yr w/ symptoms of detrusor overactivity associated w/ a neurologic condition (e.g., spina bifida).

ACTIONS: Anticholinergic, relaxes bladder smooth muscle, ↑ bladder capacity.

DOSE: Adults: 5 mg BD-TID; 5 mg every 12hr max. 5–10 mg, 30 mg max.

Ped: ≥ 5 yr: 5 mg PO BD-TID; 15 mg max.

Ped: 1–5 yr: 0.2 mg/kg/day 2–4 mg (group 5 mg/5 mL); 15 mg max.; ↓ to 1 mg in elderly; periodic drug holidays OK.

W/P: [B, ?/L, ?/O].

C: Naurone–angle glaucoma, myasthenia gravis, G6PD, allergic colitis, myoglobin, megaloblastosis.

DISP: Tabs 5 mg; XL tabs 10, 15 mg group 5 mg/5 mL.

SE: Anticholinergic (drowsiness, xerostomia, constipation, tachycardia), QT interval, memory impairment; ER form empty shell expelled in stool.

NOTES: See topical forms of oxybutynin.

OXYBUTYNIN, TOPICAL (GELIQUE)

USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency, frequency.*

ACTIONS: Anticholinergic, relaxes bladder smooth muscle, ↑ bladder capacity.

DOSE: 1 g cadet gel to dry skin (submucosal/urethral/rectal/genera arms).

W/P: [B, ?/L, ?/O].

C: Gastric or urinary retention; narrow–angle glaucoma.

DISP: Gel 10%, 1-g sachets (100 mg oxybutynin).

SE: Anticholinergic (drowsiness, xerostomia, constipation, blurred vision, T HR rise, pruritus, redness, pain at site; UTI).

NOTES: Cover w/ clothing, skin-to-skin transfer can occur; gel is flammable, after applying wait 1 hr before showering.

OXYBUTYNIN TRANSDERMAL SYSTEM (OXYTROL, OXYTROL FOR WOMEN [OTC])

USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency.*

ACTIONS: Anticholinergic, muscarinic antagonist; relaxes bladder smooth muscle, ↑ bladder capacity.

DOSE: One 3.9 mg system apply 2×/wk (q3–4d) to abdomen, hip, or buttock.

W/P: [B, ?/L, ?/O].
OXYCODONE/ACETAMINOPHEN ER (XARTEMIS XR) [CII]

**ACNE**: Acute pain that requires opioids where alternatives are inadequate.

**USES**: Acute pain.

**NOTES**: Do not apply to same site w/in 7 days.

**PACKAGE**: OxyContin 10, 15, 20, 30, 40, 60, 80, 160 mg; liq 4.83 mg oxycodone hydrochloride, 325 mg aspirin; soln 5 mg oxycodone & 325 mg acetaminophen/5 mL.

**INDICATIONS**: Narcotic analgesic w/ NSAID.

**USES**: Mod–severe pain.

**NOTES**: Check renal function; abuse potential w/ oxycodone.

**PACLITAXEL (ABRAXANE, TAXOL, GENERIC)**

**ACNE**: Administration only by physician experienced in chemotherapy; fatal anaphylaxis and hypersensitivity possible; severe myelosuppression possible.

**USES**: Chemoreduction chemotherapeutic agent, non-clear cell lung cancer.

**NOTES**: Myelosuppression.

**OXYCODONE/ACETAMINOPHEN PERCOCET, TYLEX [C-II]

**WARNING**: Acetaminophen has been associated with cases of acute liver failure, at times resulting in liver transplant and death. Most of the cases of liver injury are associated with the use of acetaminophen at doses that exceed 4,000 mg/d, and often involve more than 1 acetaminophen-containing product.

**USES**:Mod–severe pain.

**ACTIIONS**: Narcotic analgesic.

**DOSE**: Adults: 1–2 tablets/caps PO q4–6h PRN (pergadine hydrochloride, 4 mg; oxycodone hydrochloride, 5 mg; aspirin, 325 mg).

**SE**: Allergy, paralytic ileus, resp depression.

**DISP**: Peroral tablets/capsules, extended-release.

**ANNEX**: Component allergy. Relative hepatic and renal impairment. Acute maalaise, dizziness, constipation, abdominal pain.

**NOTES**: Check renal function, abuse potential w/ oxycodone.

**OXYCODONE/ACETAMINOPHEN COMBUNOX [C-II]

**ACNE**: Acute pain that requires opioids where alternatives are inadequate.

**USES**: Acute pain.

**NOTES**: Do not apply to same site w/in 7 days.
**PENICILLIN G BENZATHINE (BICILLIN)**

**USES:** Single-dose regimen for streptococcal pharyngitis, rheumatic fever, gono/borreliosis, syphilis.

**DOSE:** Based on indication range 0.6–24 MU in – doses q4h.

**Pharmacodynamics:**
- Bactericidal; + / †; less effective against meningococci.
- Spectrum: + / †.
- Spectrum: + / † / ††.
- Spectrum: + / † / †† / †††.
- Spectrum: + / † / †† / ††† / ††††.
- Spectrum: + / † / †† / ††† / †††† / †††††.
- Spectrum: + / † / †† / ††† / †††† / †††††.

**Side Effects:**
- Allergic reactions: rash, urticaria, angioedema.
- Cardiovascular: hypotension, bradycardia.
- Gastrointestinal: nausea, vomiting, diarrhea.
- Hematologic: anemia, leukopenia, thrombocytopenia.
- Hepatic: jaundice, cholestasis.
- Renal: acute tubular necrosis.
- Respiratory: wheezing, bronchospasm.
- Skin: rashes, urticaria, angioedema.
- Ophthalmic: photophobia, blurring of vision.

**Precautions:**
- Strict adherence to dosing schedule is essential.
- Pregnancy: Category B.
- Lactation: Generally accepted as safe.
- Children: Doses should be adjusted based on body weight.
- Adolescents: No specific dosage recommendations.
- Elderly: No dose adjustment usually required.
- Renal impairment: No dose adjustment generally required.
- Hepatic impairment: No dose adjustment generally required.
- Allergic reactions: Preceding dose with antihistamines and/or corticosteroids is recommended.
- Drug interactions: Beta-lactamase inhibitors (e.g., clavulanate) may enhance bactericidal activity.

**Pharmacokinetics:**
- Absorption: Rapid intramuscular injection.
- Distribution: Widely distributed in body tissues and fluids.
- Metabolism: Mostly by metabolism in the liver.
- Excretion: Primarily by renal excretion.

**Interactions:**
- OTC: Tylenol, Motrin, Advil, ibuprofen, aspirin.
- Rx: Nonsteroidal anti-inflammatory drugs (NSAIDs), oral anticoagulants.

**Contraindications:**
- Hypersensitivity to penicillins.
- History of anaphylaxis.
- Severe renal or hepatic dysfunction.
- Pregnancy (Category B).
- Lactation.

**Dosage:**
- Adults: 6–9 MU SQ 1–2×/wk; Children: 0.9–1.8 MU/kg/dose q4h.
DOSE: Adults: 1.2–2.4 mg/L, deep 8 lg/mL q–4h.
Ped: 50,000 U/kg/dose, 2.4 mg/dose max.; deep IM q–4 wk.
W/P: [B, M].
CI: Allergy.
DISP: [I] 300,000, 600,000 U/mL; [B] 2–4 mL of benzathine or procaine (300,000 U procaine or 300,000 U benzathine w/ 300,000 U procaine [2 mL]).
SE: [I] oral pain, acute interstitial nephritis, anaphylaxis.
NOTES: IM can only sustain a dosage, w/ levels up to 4 wk; drug of choice for noncongenital syphilis.

PENTASAN POLYSULFATE SODIUM (ELMIRON)

USES: "False paincomfort w/ interstitial cystitis."

ACTIONS: Bladder wall buffer.
K20 mEq/h, max. 40 mEq/h & 150 mEq/d (monitor when the urine pH is >6.5). Use w/ caution in renal insufficiency; metabolic alkalosis. Rule out bowel obstructions before use.

**PROBENECID (PROBANAL, GENERIC)**

**DOSE:**
- Adults: 500 mg PO TID, 1 to 3 wk based on response, 350 mg max, renal impairment (90–100 mg/d or 150 mg PO QID for 3 wk max).
- Initial dose: 500 mg PO QID for 1 wk; then 250 mg PO QID for the remainder of therapy.

**USAGES:**
- Malignant hyperthermia, acute gout.

**ACTIONS:**
- Inhibits urate reabsorption in proximal tubules, competes with urate for renal tubule transport sites.

**SIDE EFFECTS:**
- Headache, GI upset, rash, pruritus, dizziness, palpitations, edema, uric acid kidney stones.

**NOTES:**
- Reduce dose in renal impairment or elderly.

**PROPRANOLOL (INDERAL LA, COMPASS) (PRO-BANTHINE, GENERIC) (GENERIC)**

**DOSE:**
- Adults: 80–220 mg PO QD, 1–2 wk, then 160–240 mg PO QD in 3–4 wk.
- Prophylaxis for migraine headache: 150 mg PO QD for 1 wk, then 100 mg PO bid to 600 mg/day based on response.

**USAGES:**
- Migraine prophylaxis.

**ACTIONS:**
- β-Antagonist.

**SIDE EFFECTS:**
- Headache, GI upset, rash, pruritus, dizziness, palpitations, edema, uric acid kidney stones.

**NOTES:**
- Reduce dose in renal impairment or elderly.

**PROLONGED-RELEASE FORMULATIONS**

**DOSE:**
- Adults: 80 mg PO bid or 160 mg PO qd, titrate to 120–240 mg PO qd max.

**USAGES:**
- Blood pressure control.

**ACTIONS:**
- Increases diastolic pressure.

**SIDE EFFECTS:**
- Headache, palpitations, edema, uric acid kidney stones.

**NOTES:**
- Reduce dose in renal impairment or elderly.

**PYRAZINAMIDE (GENERIC)**

**DOSE:**
- Adults: 250 mg PO QD for 1–2 wk; then 500 mg PO QD for 1–2 wk; then 1,500 mg PO QD for 3 wk max.

**USAGES:**
- Anti-tuberculosis.

**ACTIONS:**
- Bacteriostatic; unknown mechanism.

**SIDE EFFECTS:**
- Headache, GI upset, rash, pruritus, dizziness, blood dyscrasias.

**USES:**
- Anti-tuberculosis.

**NOTES:**
- Reduce dose in renal impairment or elderly.

**PSEUDOSPEHEDRINE (MANY OTC MONO AND COMBINATION BRANDS)**

**DOSE:**
- Adults: Up to 3 mg IV bolus q10min

**USAGES:**
- Retrograde ejaculation.

**ACTIONS:**
- Non-selective α-1 and β-1 blockers.

**SIDE EFFECTS:**
- Headache, palpitations, edema, uric acid kidney stones.

**NOTES:**
- Reduce dose in renal impairment or elderly.
RISEDORANE, DELAYED RELEASE (ATELVIA)

USEs: *Piglet disease; Treatment prevention pneumococci-induced postsurgical osteoporosis, 1 bone mass in osteoporotic men; w/ calcium only FDA approved for female osteoporosis.*

ACTIONS: Bisphosphonate, 1 osteoclast-mediated bone resorption.

DOSE: Piglet disease: 30 mg PO for 2 mo. Osteoporosis Pneumococcal 5 mg daily or 35 mg qwk or 150 mg qtr 30 min before 1st food/drink of the day. pig weight for least 30 min after dose.

NOTES: Desloratadine, as strontium.

RIFAMPIN (RIFADIN, RIMACTANE, GENERIC)

USEs: *TB & treat & prophylaxis of N. meningitidis, H. influenzae, S. aureus, S. pyogenes; adjunct w/ severe infection.*

ACTIONS: *Ribosomal protein synth.*

DOSE: Adults: N. meningitidis & H. influenzae carrier: 600 mg PO for 4 d. ER 600 mg PO or IV daily or 2 × 300 mg w/ combo regimen.

W/P: [C, X+] −; [Fosamprenavir, multiple drug interaction.*

WARNING: Allergy, active fl. meningococcal infection, w/ saquinavir/ritonavir.

DISP: Caps 150, 300 mg; [R, B] +; [S, Y] −.

NOTES:从未 use as single agent w/ active TB.

RISEDORANE, DELAYED RELEASE (ATELVIA)

USEs: *TB & treat & prophylaxis of N. meningitidis, H. influenzae, S. aureus, S. pyogenes; adjunct w/ severe infection.*

ACTIONS: *Ribosomal protein synth.*

DOSE: Adults: N. meningitidis & H. influenzae carrier: 600 mg PO for 4 d. ER 600 mg PO or IV daily or 2 × 300 mg w/ combo regimen.

W/P: [C, X+] −; [Fosamprenavir, multiple drug interaction.*

WARNING: Allergy, active fl. meningococcal infection, w/ saquinavir/ritonavir.

DISP: Caps 150, 300 mg; [R, B] +; [S, Y] −.

NOTES:从未 use as single agent w/ active TB.
Rivaroxaban (Xarelto)

USES:
- Reduces the risk of pulmonary embolism (PE) and deep vein thrombosis (DVT) in patients with medical conditions associated with an increased risk of venous thromboembolism (VTE) who are candidates for thromboprophylaxis in the setting of acute medical illness (AMI), including medical surgery, medical illness, and medical conditions (eg, prolonged immobilization, major medical illness, or major surgery) that require hospitalization.

NOTES: Consider the risk of bleeding vs the benefits of using rivaroxaban, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Sirolimus (Rapamune, Zortress)

WARNING:
- May increase the risk of aortic regurgitation and decrease arterial compliance.

USES:
- Used as an immunosuppressant to prevent rejection following organ transplantation.

NOTES: Consider the risk of bleeding vs the benefits of using sirolimus, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Silodosin (Rapaflo)

USES:
- Used as a 5-alpha reductase inhibitor to treat benign prostatic hyperplasia (BPH).

NOTES: Consider the risk of bleeding vs the benefits of using silodosin, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Sevelamer Hydrochloride (Renagel)

USES:
- Used to bind phosphate in the gut and lower serum phosphorus levels in patients with renal failure to prevent the development of secondary hyperparathyroidism.

NOTES: Consider the risk of bleeding vs the benefits of using sevelamer hydrochloride, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Silver Nitrate (Generic)

USES:
- Used to remove granulation tissue and warts, treat prostatitis, and prevent urinary tract infection.

NOTES: Consider the risk of bleeding vs the benefits of using silver nitrate, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Silver Sulphadiazine (Silvadene, Generic)

USES:
- Used as a topical antiseptic to prevent and treat infection in 2nd- and 3rd-degree burns.

NOTES: Consider the risk of bleeding vs the benefits of using silver sulphadiazine, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Sipuleucel-T (Provenge)

USES:
- Used to treat asymptomatic or minimally symptomatic metastatic castrate-resistant PCa.

NOTES: Consider the risk of bleeding vs the benefits of using sipuleucel-T, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Sildenafil (Viagra, Revatio)

USES:
- Used to treat erectile dysfunction in men who have vardenafil or tadalafil intolerance.

NOTES: Consider the risk of bleeding vs the benefits of using sildenafil, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Sargramostim (GM-CSF, Leukine)

USES:
- Used to stimulate myeloid recovery following bone marrow transplantation.

NOTES: Consider the risk of bleeding vs the benefits of using sargramostim, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Silodosin (Rapaflo)

USES:
- Used as a 5-alpha reductase inhibitor to treat benign prostatic hyperplasia (BPH).

NOTES: Consider the risk of bleeding vs the benefits of using silodosin, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Sevelamer Hydrochloride (Renagel)

USES:
- Used to bind phosphate in the gut and lower serum phosphorus levels in patients with renal failure to prevent the development of secondary hyperparathyroidism.

NOTES: Consider the risk of bleeding vs the benefits of using sevelamer hydrochloride, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Silver Nitrate (Generic)

USES:
- Used to remove granulation tissue and warts, treat prostatitis, and prevent urinary tract infection.

NOTES: Consider the risk of bleeding vs the benefits of using silver nitrate, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Silver Sulphadiazine (Silvadene, Generic)

USES:
- Used as a topical antiseptic to prevent and treat infection in 2nd- and 3rd-degree burns.

NOTES: Consider the risk of bleeding vs the benefits of using silver sulphadiazine, especially in patients with a bleeding tendency or those at increased risk for bleeding.

Sipuleucel-T (Provenge)

USES:
- Used to treat asymptomatic or minimally symptomatic metastatic castrate-resistant PCa.

NOTES: Consider the risk of bleeding vs the benefits of using sipuleucel-T, especially in patients with a bleeding tendency or those at increased risk for bleeding.
SODIUM BICARBONATE

USES: Alkalization of urine, RTA, metabolic acidosis, \( \text{K}^{+} \), \( \text{H}^{+} \), tricyclic antidepressants OD, alkalize bladder prior to transcatheter retrograde ejaculation.

ACTIONS: Alkalizing agent.

DOSE: Adults: EICC 2010: Cardiac arrest w/ good ventilation, hydration, O2 of TCA, ASA, ouabain, diphosphopyridine: 1 mEq/kg IV bolus; repeat 1/2 dose q15min PHN. Metabolic acidosis: 2–5 mEq/kg IV over 6 hr & PHN based on acid-base status. 
- \( \text{K}^{+} \): 50 mEq IV over 5 min. Alkalize urine: 4.4 mEq/kg PO, then 12–24 mEq q6h. Adjust based on urine pH. 2 amp (100 mEq) IV IV at 100–250 mL/h. Monitor urine pH & serum bicarbonate. chronic renal failure: 1–3 mEq/l. D5W: 0.5–2 mEq/1 in 4–5 doses.
- Peds: Severe metabolic acidosis, hyperkalemia: 1 mEq/kg IV slow bolus. 4.2% in Infusion: 1–1.5 m. Chronic renal failure: See Adult dosage. D5W: TMA: 2–3 mEq/kg PO. Proximal RTA: 5–10 mEq/kg. titrate based on serum bicarbonate. urine alkalization: 84–840 mEq (10–100 mEq) in – dosing. Adjust based on urine pH.
- W/P: [C, 7].
- CI: Alkalosis, \( \text{Na}^{+} \), severe pruritus (using \( \text{Ca}^{2+} \)).
- DISP: PO: tablets: 325 mg = 3.8 mEq; 810 mg = 7.6 mEq IV (1 mEq/l IV), 4.2 (5 mEq/10 mL). 5.5 (8.85 mEq/10 mL). 8.4 (10 mEq/5 mL) vial or amp.
- SE: Nausea, vomiting, diarrhea, rash, \( \text{Na}^{+} \), metabolic alkalis.
- NOTES: \( 1 \text{g neutralizes} 12 \text{mEq of acid} \), \( 50 \text{mEq bicarbonate} = 50 \text{mEq} \text{KCl} \), can make 3 amp 1 L D5W w/ 150 mEq bicarbonate.

SODIUM CITRATE/CITRIC ACID (ORACIT)

USES: Chronic metabolic acidosis, alkalize urine; dissolve acid urolithiasis urine.

ACTIONS: Urinary alkalinization.

DOSE: Adults: 10–30 mL in 1–3 oz H2O q8–12 h & hs or by mouth. 
- Peds: 5–15 mL in 1–3 oz H2O q8–12 h & hs; best after meals.
- W/P: [C, 7].
- CI: Severe renal impairment, oliguria or azotemia, uncontrolled Addison’s disease, adynamia episodic hernia, acute dehydration, heat cramps, anuria, severe myocardial damage, and hypokalemia.
- DISP: 15–30 mL unit dose: 16 (673 mL) or 4 oz.
- SE: Tasting, metabolic alkalinosis, \( \text{K}^{+} \). Gluconate, avoid use of multiple 35 mL amp; can cause ↑ \( \text{Na}^{+} \) hyperosmolality.
- NOTES: \( 1 \text{mL} = 1 \text{mEq Na} \& 1 \text{mEq bicarbonate.} \)

SODIUM PHOSPHATE (OSMOPREP, VISICOL)

WARNING: Acute phosphate nephropathy reported w/ permanent renal impairment risk; \( \text{K}^{+} \), hyperkalemia, bowel obstruction, baseline kidney disease, w/ meds that affect renal perfusion/function (eg, diuretics, ACE inhibitor, ARB, NSAIDs).

USES: Bowel prep prior to colonoscopy in adults, short-term constipation.

ACTIONS: Hypo-osmotic laxative.

DOSE: Peds: PO w/ at least 8–10 oz H2O q6h. 15–20 mL for 6 doses; then 2 additional tabs in 15 min, 3–5 hr prior to colonoscopy. 1 tab q6h for 6 doses, then 2 additional tabs in 15 min.
- W/P: [C, ] renal impairment, electrolyte disturbances.
- CI: Megacolon, bowel obstr.
- DISP: Tabs: 0.388, 1.02 g (32/16 tablets).
- SE: QT \( \uparrow \), PMI, 4–6 cardiac arrest, delirium, hallucinations, convulsions, abdominal bloating/ cramping.
- NOTES: Acute phosphate nephropathy is associated w/ calcium phosphate crystal deposits in the renal tubules and may result in permanent renal dysfunction. Risk factors for acute phosphate nephropathy: Age <55 yr, hyperkalemia, pre-existing renal impairment, bowel obstruction, or acute colitis; \( \text{K}^{+} \) meds that may affect renal perfusion/function (eg, diuretics, ACE inhibitors, ARBs and possibly NOX).
- SE: Hypokalemia, paralytic ileus, constipation, severe electrolyte disturbances, abdominal pain, nausea, vomiting, diarrhea.
- NOTES: Monitor BP 1st 6 hr; may require \( \text{K}^{2+} \) dose (daily or no other day). Severe hypophosphatemia (\( \leq 1.5 \text{mEq/l} \)), \( \text{Na}^{+} \), alkalosis, \( \text{K}^{+} \), hyperkalaemia.
- DISEASES: Balkan dialysis, \( \uparrow \) AKI.

SODIUM POLYSTYRENE SULFONATE (KAYEXALATE, KONEX, GENERIC)

USES: Treat of \( \uparrow \text{K}^{2+} \).

ACTIONS: Na\( ^{+} \text{K}^{2+} \) ion-exchange resin.

DOSE: Adults: 15–60 g PO or 30–50 g PR q8h based on serum \( \text{K}^{+} \).
STARCH, TOPICAL, RECTAL (TUCKS SUPPOSITORIES [OTC])

USING: Temporary relief of itching, pruritus, rash

DOSE: Topical protectant

W/P: [?, ?]

STEROIDS, SYSTEMIC (SEE TABLE AT BOTTOM OF PAGE)

The following relates only to the commonly used systemic glucocorticoids.

DOSE: Varies w/ use & institutional protocols.

• Adrenal insufficiency, acute: Adults: Hydrocortisone: 100 mg IV then 300 mg/d — q8h for 48 hr then convert to 50 mg PO q8h = 6 doses, taper to 30–50 mg — BID. Peds: Hydrocortisone: 1–2 mg/kg daily then 150–250 mg daily — q6–8h.

• Adrenal insufficiency, chronic (physiologic replacement): May need mineralocorticoid supplement such as Florinef: Adults: Hydrocortisone: 20 mg PO q a.m., 10 mg PO p.m.; cortisone: 25–35 mg PO daily. Dexamethasone: 0.3–0.5 mg/d or 0.6–0.75 mg q14–q16 hr; 4–12 mg PO, IM, IV. Peds: Hydrocortisone: 8–10 mg/m2/d — q6h; some may require up to 12 mg/m2/d. Hydrocortisone succinate: 0.25–0.35 mg/kg/d.

• Adrenal, acute: Adults: Methylprednisolone 40–80 mg/d IV in 1–2 doses PO or IV over 30–60 min — q8h. Peds: Prednisolone 1–2 mg/kg/d or prednisone 1–2 mg/kg/d — daily – BID for up to 5 days. methylprednisolone 12 mg IV q8h — BID; dexamethasone 0.1–0.3 mg/kg — q6h.

• Congenital adrenal hyperplasia: Peds: Initial hydrocortisone 10–30 mg/m2/d in 3–4 doses.

• Status asthmaticus: Adults: Dexamethasone: 0.5–2 mg/kg IV (M, q12h — q8h, then 0.5–1 mg/kg/d IV or IM — BID (if tolerated). Peds: Dexamethasone: 0.5–2 mg/kg — q6h (start 24 hr before & cont for 4–6 doses after extubation).

• Immunosuppressant—corticosteroids:
  • Adults: Prednisone: 50–60 mg PO q24h (start at 0.5–1 mg/kg/d — BID (if tolerated).
  • Adults: Hydrocortisone: 15–240 mg PO q6h (M, q12h — q8h, then 0.5–1 mg/kg/d IV — BID (if tolerated).

• Rheumatic disease: Adults: Prednisone: Prednisolone: 2–4 mg/kg/d PO or IV — q6h. Peds: Hydrocortisone: 1–2 mg/kg/d intermittent or continuous inf. may thrice up to 50 mg/h.

• Status asthmaticus: Adults & Peds: Hydrocortisone: 1–2 mg/kg IV q4h for 24 hr; then q6h (start at 0.5–1 mg/kg/d). Dexamethasone: 0.5–2 mg/kg IV q8h (start 24 hr before & cont for 4–6 doses after extubation).

• Hydrocortisone: Use lowest potency product for shortest period for effect (see Table next page)

neuromuscular blockage w/ respiratory paralysis. Administer or application may cause adrenal suppression or hyperglycemia. 

USES: * Neuro/oto/renal toxicity possible; Skin atrophy w/ chronic use; chronic

SE: * Monitor levels: Peak: 20–30 μg/mL, trough: <5 μg/mL, TAC peak: >50, TAC: 

DOSE: Adults: 1 g, max 3 g/weight (max: 1 g). PO: 15 mg/kg/dose w/ CYP3A4 inhibitor, 

STRONTIUM-89 CHLORIDE (METASTRON) 

USES: Bone pain in patients with various metastatic.

ACTIONS: Ca\(^{2+}\) analogues taken up by bone in areas of active osteogenesis with selective radiation of metastasis.

DOSE: 148 MBq (4 mCi) IV slowly, or 15–22 MBq/kg. W/P [D, −].

DISP: Intrathecally.

SE: Patients nadir about 12–16 wk after treatment.

DOSE: Adults: Chew 500 mg TD w/ meals; may 1 dose weekly to target phos <5 mg/dL; max. dose studied 3,000 mg/d.

W/P: [D, −].

DISP: Tab 500 mg.

SE: None. 

REFERENCES: None. 

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose.

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose.

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose. 

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose. 

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose. 

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose. 

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose. 

DISP: Caps 12.5, 25, 50 mg.

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.

DOSE: Adults: 50 mg PO daily, = 4 wk, followed by 2 wk holiday. 1 to 37.5 mg or 5.5 mg/dL; max. dose studied 20–30 mg/kg/dose. 

DISP: Caps 12.5, 25, 50 mg.

SE: None. 

W/P: PO, −. Multiple interactions require dose modification (eg, St. John’s wort), TNF and S15 reported.
TACROLIMUS, EXTENDED RELEASE (ASTAGRAF XL)

NOTES: Monitor left ventricular ejection fraction, CO, CBC, CMP, chemistry (K, Hg, Na, PO₄, glucose), TSH & TFTs periodically; ↓ dose in 2.5 mg increments if not tolerated.

TACROLIMUS, EXTENDED RELEASE (ASTAGRAF XL)

WARNING: Only physicians experienced in immunosuppression should prescribe. ↑ Risk of malignancy; use in heart transplant not recommended for frailty in female patients. USES: "To kidney transplant rejection w/ MMF and steroids, w/ or w/o basiliximab induction."

ACTIONS: Calcineurin inhibitor/immunosuppressant.

DOSE: → w/ basiliximab induction: 0.15 mg/kg/day (target level day 1–6: 5–17 ng/mL; Mon 3–12: 4–12 ng/mL). w/o induction: Peak 0.1 mg/mL; postop 0.2 mg/mL (target level Day 1–6: 6–20 ng/mL; Mon 3–12: 6–14 ng/mL). Take daily a.m.; empty stomach; do not take w/ alcohol or grapefruit juice; take whole.

W/P: [C, -] → not interchangeable w/ immediate release; follow glucose, Cs, K*, can ± BP can ± QT interval; do not use w/ sirolimus, CYP3A4 inhibitors, avoid live vaccines, monitor for red cell aplasia w/ Cytoxan; avoid topical if <2 yr; Neuro & nephrotoxic, ↑ risk opportunistic infections; avoid grapefruit juice.

Cl: Component allergy, castor oil allergy w/ IV form.

DISP: ER Caps 0.5, 1, 5 mg.

SE: N, constipation, edema, tremor, anemia.

NOTES: Monitor levels; African Americans may need ↓ dose; use tacrolimus immediate release.

TACROLIMUS, IMMEDIATE RELEASE (PROGRAF, GENERIC)

WARNING: ↑ Risk of infection and lymphoma. Only physicians experienced in immunosuppression should prescribe.

USES: "Prevent organ rejection (kidney/heart/liver)."

ACTIONS: Calcineurin inhibitor/immunosuppressant.

DOSE: Adults: IV: 0.03–0.05 mg/kg in kidney and liver, 0.03 mg/kg in heart or liver. Peds: IV: 0.03–0.05 mg/kg as cont inf. PO: 0.15–0.2 mg PO = 0.18. Adults & Peds: Femoral → empty stomach; ↓ w/ hepatic impairment.

W/P: [C, -] → w/ Cytoxan; avoid topical if <2 yr; Neuro & nephrotoxic, ↑ risk opportunistic infections; avoid grapefruit juice.

Cl: Component allergy, castor oil allergy w/ IV form.

DISP: Caps 0.5, 1, 5 mg, 10 mg.

SE: HTN, edema, headache, insomnia, fever, pruritus, ↑2 K*, hyperglycemia, GI upset, anemia, leukopenia, tremors, pancreatitis, pleural effusion, seizures, lymphoma, PPIs, GI nephrotoxicity, PNH.

NOTES: Monitor levels; ↑ glucose, 5–12 ng/mL, based on indication and time since transplant.

TADALAFIL (CIALIS)

USES: Erectile dysfunction, BPH, alone or together.

ACTIONS: PDE5 inhibitors, ↑ cyclic guanosine monophosphate (cGMP) & NO levels; relax smooth muscles, dilates coronary arteries, 15–120 min, duration 24–36 hr.

DOSE: Adults: IV: 10 mg PO before sexual activity (5–20 mg max. based on response). 1 dose/24 h. Daily dosing: 2.5 mg PO, may ↑ to 5 mg PO, w/o regard to meals. BP therapy related with tadalafil and fosfomorphate, nadalid dose is 5 mg for up to 26 wk; ↓ w/ renal/hypertensive dysfunction, 5 mg not more than once in every 72 hr or ↓ O(2) <30 mmHg/ERD on dialysis.

W/P: [B, -] → w/ Blockers (except tamsulosin), use w/ CYP3A4 inhibitor 2.5 mg/day dose or 5 mg PNU dose; ClO = 0 mL/min; HTN/diabetes/severe hepatic impairment, do not use daily dosing.

Cl: Therapeutic.

DISP: Tabs: 2.5, 5, 10, 20 mg.

SE: Headache, flushing, dyspnea, back/limb pain, myalgia, nasal congestion, urticaria, SJS, dermatitis, angioedema, intraoperative floppy iris syndrome.

NOTES: Longest acting of class (36 hr); daily dosing may ↑ drug interactions; excessive EOD may ↑ orthostasis, transient global amnesia report; not recommended in combo w/ α-blocker for BPH.

TAMSULOSIN (FLOMAX, GENERIC)

USES: "BPH: medical therapy for urinary stenosis.

ACTIONS: Antagonist of prostatic α-receptors.

DOSE: 0.4 mg/day, may ↑ 0.8 mg PO daily.

W/P: [B, ?] [↑] Flapcy's syndrome w/ cataract surgery. DISP: Caps 0.4 mg.

SE: Headache, dizziness, syncope, somnolence, ↓ BP; ↓ renal, metabolic, cardiovascular, orthostatic hypotension (OHN), sudden, ↓ loss of hearing, retention.

NOTES: Longest acting of class (36 hr); daily dosing may ↑ drug interactions; excessive EOD may ↑ orthostasis, transient global amnesia reports; not recommended in combo w/ α-blocker for BPH.

TERBINAFINE (TORISEL, GENERIC)

USES: "Antifungal agent.

ACTIONS: Multikinase inhibitor, ↓ mTOR (maximum target of rapamycin), ↓ hypoxic-induced factors, ↓ VEGF.

DOSE: 25 mg IV 30–60 min 1 x/wk. Hold w/ ANC <1,000 cells/uL, ↓ ph = 75–700 cells/uL, or NC1 grade 3. Revise when tox grade 2 or less, restart w/ dose ↓ 2.5 mg not <15 mg/kg w/ CYP3A4 inhibition; ↓ 12.5 mg/kg w/ CYP3A4 inhibitors; ↓ 50 mg/kg.

Cl: [B, -] → Avoid live vaccines, ↓ wound healing, avoid psoralen.
TESTOSTERONE, IMPLANT (TESTOPEL) [C-II]

USES: "Male hypogonadism (congenital/acquired)."

ACTIONS: Testosterone replacement.

DOSE: 150-450 mg (2-6 pellets) SQ implant (implant two 75-mg pellets for each 25-mg testosterone required weekly, eg, for 75-mg pellets, implant 450 mg of 6 pellets).

W/P: [X, — May cause polyuria, worsening of BPH Sx, prostate cancer: patients may use O2, CrF; may use O2, increased glucose and insulin requirements; venous thrombosis risk.

Cl: PSA, male breast CA, PRG woman.

DISP: 75 mg implant (3.2 mm × 9 mm).

SE: Pain/Inflamm at site, gynecomastia, excessive sweating, dizziness, hirsutism, male pattern baldness, acne, retention of sodium and edema, suppression of clotting factors, polyuria, Na, jaundice, T 4/Thyroxine, anterior pituitary hormones, NE, hypothyroidism, and pelvis hepatitis, 11β lipoid, sleep apnea, T PSA.

NOTES: Check levels and adjust PRN (500–1,000 ng/dL testosterone range). Follow periodic DPT and CBC; typical site upper outer posterior gluteal region using sterile technique. Local anesthesia. 4 mm stab wound and provided 166 insertion trocar.

TESTOSTERONE, NASAL GEL (NATESTO) [C-II]

WARNING: Utilization reported in children exposed to topical testosterone products. Children to avoid contact w/ unwashed or unclothed application sites.

USES: "Adult male hypogonadism (congenital/acquired)."

ACTIONS: Testosterone replacement.

DOSE: 2 pumps each nostril (11 mg testosterone) in each nostril; T/D (total 33 mg/3); blow nose before use; avoid bleaching for 1 hr after.

W/P: [X, — Avoid with nasal pathology, monitor BPH Sx and for DVT, may cause azoospermia, edema, sleep apnea; not rec if < 19 yr, venous thrombosis risk.

CI: Prostate cancer, male breast cancer, women.

DISP: Metered-dose pump; 1 pump = 5.5 mg of testosterone.

SE: 1 PSA, headache, rhinorrhea, epistaxis, nasal discomfort, nasal polyps, broken, OI, CrF, nausea, nasal scale; 1 pump = 5.5 mg of testosterone.

NOTES: Previously known as Complexx/RT, may minimize exposure of testosterone to women or children; check testosterone, PSA, Hgb, LFTs, and lipids periodically.

TESTOSTERONE, TOPICAL (ANDROGEL 1%, ANDROGEL 1.62%: ANDRODERM, AXIRON, FORTESTA, STRIANT, TESTIM, VOGELXO) [C-III]

WARNING: Utilization reported in children exposed to topical testosterone products. Children to avoid contact w/ unwashed or unclothed application sites.

USES: "Male hypogonadism (congenital/acquired)."

ACTIONS: Testosterone replacement; 1 lean body mass, libido.

DOSE: [X, — 1,250 mg IM (glucose) initially, at 4 wk, every 10 wk thereafter; observe for 30 min for POME or anaphylaxis.

W/P: [X, — May worsen BPH Sx, azoospermia possible, edema with pre-existing cardiac/hepatic/renal Dz, sleep apnea with other risk factors, monitor PSA, headache; lifespan periodically, monitor Hb if on warfarin; we sendees may ↑ fluid retention; venous thrombosis risk.

Cl: PSA, male breast cancer, women, component unsuitability.

SE: Acne, injection-site pain, T PSA and estradiol, hypertension, fatigue, irregularity, T hemoglobin, insomnia, mood swings.

NOTES: Available only through a restricted program (Evident REMS); other ftms do not commonly used; testosterone enanthate (Delatestryl, Genrin) / testosterone cypionate (Depo-T, Testoderm) dose 144-288 w/ variable serum levels.

TETRACYCLINE (GENERIC)

USES: "Broad-spectrum antibiotic."

DOSE: Adults: 250–500 mg PO BID–QID.

PE: [X, — 8 yr; 25–50 mg/kg/24 h PO Q6–12h; w/ renal/hepatic impairment, no food preferred.

W/P: [X, —]

Cl: PREGNANCY, children < 8 yr.

DISP: Caps 100, 250, 500 mg; tabs 250, 500 mg; PO susp 250 mg/mL.

SE: Photosensitizy, GI upset, renal failure, pseudomembranous colitis, hepatic impairment.

NOTES: May cause some rash, if not severe, severe dose formation in children; do not administer w/ antacids or milk products.

TICAGRELOR (BRILINTA)

WARNING: Bleeding risk; can be fatal, daily aspirin > 700 mg may ↓ effectiveness; do not start w/ active bleeding. He intracranial bleed, planned CABG, if hypersensitive and recent procedure, suspect bleeding manage any bleed w/ DVT of eczepel.

USES: "J. CV death and heart attack in ACS."

ACTIONS: Oral antiplatelet; reversibly binding ADP receptor antagonists in GPIb.

DOSE: Initial 180 mg PO w/ ASA 325, then 90 mg BID w/ ASA 75–100 mg.

W/P: [X, —] w/ Mod hepatic impairment; w/ strong CYP3A inhibitors or CYP3A inducers.

Cl: pH extracranial bleed, active pathologic bleeding, severe hepatic impairment.

DISP: Tab 90 mg.

SE: Bleeding, SOB.

NOTES: REMS; D/C 5 days prepro.
**TICARCILLIN/POTASSIUM CLAVULANATE (TIMENTIN)**

**USES:** Infections of the skin, bone, resp & urinary tract.

**ACTIONS:** Carbapenem; β-lactamase inhibitor; Gram-negative; anaerobic; Gram-positive; susceptible to β-lactamase.

**DOSE:**
- **Adults:** PO 3.1 g IV q4–6h max. 24 g ticarcillin/2 g clavulanate.
- **Children:** PO 100 mg/kg/dose IV q8h; max. 24 g ticarcillin/2 g clavulanate.
- **Infants:** PO 50–100 mg q6h–q8h.

**NOTES:**
- Elderly: ↑ dose w/ renal insufficiency.
- GI upset; rash; angioedema; urticaria; anaphylactic; anaphylactic shock; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia.

**TRAMODOL (RYBIX ODT, RYZOLT ER, ULTRAM, ULTRAM GENERIC) (C-IV)**

**USES:** Mod–severe pain.

**ACTIONS:** Centrally acting synthetic opioid analgesic.

**DOSE:** Adults: 50–100 mg PO q4–6h PRN; start 25 mg PO q6–8h; 1–2 tab to 25 mg PO QD, 1–50 mg Q4–6h (max 400 mg/d 100 mg q4–8h); 0.625 mg–5 mg/mL; 1–2 tab q4–8h; max. 400 mg/d.

**NOTES:**
- Elderly: ↓ dose w/ renal insufficiency.
- GI upset; rash; angioedema; anaphylaxis.
- Avoid EtOH; do not cut, chew ODT tabs.
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants);
- Seizures risk w/ psychotropic drugs.
- Seizures risk w/ anticonvulsants; GI upset; rash; angioedema; anaphylaxis.

**TROMBAYCIN (NEBCIN)**

**USES:** Serious gram − infections.

**ACTIONS:** Aminoglycoside; β-protein synth. Spectrum: β-lactamase.

**DOSE:**
- **Adults:** Conventional dosing: 1–2.5 mg/kg/dose IV q8h–q12h. Once-daily dosing: 5–7 mg/kg/dose q24h.
- **Pediatrics:** 1 mg/kg/dose IV q8h or q12h.

**NOTES:**
- ↑ dose w/ renal insufficiency.
- GI upset; rash; angioedema; anaphylaxis.
- Avoid EtOH; use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants).
- Use cautiously in hepatic/renal insufficiency (w/ anticonvulsants; GI upset; rash; angioedema; anaphylaxis).

**TOBRAMYCIN (THIOLA)**

**USES:** Infections.

**ACTIONS:** Aminoglycoside; β-protein synth. Spectrum: β-lactamase.

**DOSE:**
- **Adults & Peds:** 1 mg/kg dose IV q4–6h max. 2 tab PO q4–6h max. 100 mg w/ renal insufficiency.

**NOTES:**
- ↑ dose w/ renal insufficiency.
- GI upset; rash; angioedema; anaphylaxis.
- Avoid EtOH; use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants; GI upset; rash; angioedema; anaphylaxis).

**TIOCONAZOLE (NERITIN) (OTC)**

**USES:** Vaginal fungal infections.

**ACTIONS:** Topical antifungal.

**DOSE:**
- **Adults:** PO 250–500 mg.
- **Children:** PO 50 mg; ER 100, 200, 300 mg; Rybix ODT 100 mg.

**NOTES:**
- Avoid EtOH; abuse potential d/t prodrug.
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants).
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants; GI upset; rash; angioedema; anaphylaxis).

**TICARCILLIN/POTASSIUM CLAVULANATE (TIMENTIN)**

**USES:** Infections of the skin, bone, resp & urinary tract.

**ACTIONS:** Carbapenem; β-lactamase inhibitor; Gram-negative; anaerobic; Gram-positive; susceptible to β-lactamase.

**DOSE:**
- **Adults:** PO 3.1 g IV q4–6h max. 24 g ticarcillin/2 g clavulanate.
- **Children:** PO 100 mg/kg/dose IV q8h; max. 24 g ticarcillin/2 g clavulanate.
- **Infants:** PO 50–100 mg q6h–q8h.

**NOTES:**
- Elderly: ↑ dose w/ renal insufficiency.
- GI upset; rash; angioedema; anaphylactic; anaphylactic shock; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia; hypocalcemia; hypomagnesemia; hypophosphatemia; hyperkalemia.

**TRAMODAL/ACETAMINOPHEN (ULTRACET) (C-IV)**

**USES:** Short-term treat acute pain (<5 days).

**ACTIONS:** Centrally acting synthetic opioid analgesic.

**DOSE:** 2 tabs PO q4–6h PRN; 1 tab max.

**NOTES:**
- Avoid EtOH; use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants).
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants; GI upset; rash; angioedema; anaphylaxis).

**TOLERODINE (DETROL, DETROL LA, GENERIC)**

**USES:** Overactive bladder with symptoms of urgency, urinary incontinence, urge, and frequency.

**ACTIONS:** Anticholinergic; muscarinic receptor antagonist.

**DOSE:**
- Detrol: 1–2 mg PO BID, Detrol LA: 2–4 mg LA.
- ER, GENERIC: 1–2 mg LA PO q24h.

**NOTES:**
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants; GI upset; rash; angioedema; anaphylaxis)

**TIOCONFLOX (THIOLA)**

**USES:** Prevent cystine urolithiasis in patients with severe homozygous cystinuria with urinary cystine >500 mg/dl, who are resistant to conservative measures. High fluid intake, alkali and diet modification, or have adverse reactions to β-lactam.

**ACTIONS:** Prevents cystine urolithiasis in patients with severe homozygous cystinuria with urinary cystine >500 mg/dl, who are resistant to conservative measures. High fluid intake, alkali and diet modification, or have adverse reactions to β-lactam.

**DOSE:**
- **Children:** PO once-daily dosing: 1–2 mg/kg/dose IV q8h (at least 15 mg/kg/dxl divided 4 doses); 1 mg/kg/dose IV q12h (at least 15 mg/kg/dxl divided 2 doses).
- **Adults & Peds:** 50 mg PO q6h; 25 mg PO q4h.

**NOTES:**
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants; GI upset; rash; angioedema; anaphylaxis).
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
- Use cautiously in chronic pain (w/ tranquilizers or antidepressants; GI upset; rash; angioedema; anaphylaxis).

**TRIMETHOPRIM/SULFAMETHOXAZOLE (TRIMOPRIM/SULFADIAZINE)**

**USES:** Antifungal & anti-inflammatory.

**DOSE:** Apply lightly to area BID; max. 25 mg/d.

**NOTES:**
- Variants: systemic fungal infections.
- Use cautiously in hepatic/renal insufficiency; severe renal insufficiency.
SE: Local irritation, hypertrophic, pigment changes.
NOTES: For short-term use (~7 days). See also nystatin.

TRIAMTERENE (OXYBENNUM)
WARNING: Hyperkalemia can occur.
USES: Edema associated w/ CHF, cirrhosis.
ACTIONS: K⁺ sparing diuretic.
DOSE: Adults: 50–100 mg PO QD – 2×4 wk; q1–4 wk.
W/P: [C (expert opinion), 1].
CI: K⁺, renal impairment; caution w/ other K⁺ sparing diuretics.
DISP: Caps 50, 100 mg.
SE: —.

TRIETHYLENETHIOPHOSPHORAMIDE (THIOPETA)
USES: Breast, ovarian cancer, lymphomas (cholecyturic used) prophylactic regimen for alliegenic & ABMT w/ high doses, intravesical for bladder cancer, Intravesical effusions.
ACTIONS: Polyfunctional antithymic agent.
DOSE: For protocol typical 0.3–0.4 mg/kg IV q1–4 wk. Eflornithine: Intravesical 0.6–0.6 mg/kg 60 mg into the bladder & retained 2 hr q1–4wk; 900–125 mg; in ABMT regimen (highest dose w/o ABMT is 160 mg/kg), 4 in renal failure.
W/P: [D, —] w/ IF suppression, renal and hepatic impairment.
CI: Component allergy.
DISP: Hg 15 mg.
SE: —.

TRIETHYLMETHOXAZOLE & SULFAMETHOXAZOLE (SMX) [CO-TRIMOXAZOLE, TMP-SMX] (BACTRIM, BACTRIM DS, SEPTRAS, DS, GENERIC)
USES: U/TI, Trichomoniasis, Chlamydia, Shigellosis, Pneumonia by gram +, – organisms; PO Treat w/ dapsone & ABMT w/ high doses, Intravesical for bladder cancer, Synergistic combo, interacts w/ warfarin.
ACTIONS: Synthetase inhibitors. Close monitoring required for patients w/ preexisting renal impairment.
DOSE: Adults: 60 mg PO SID or 20 mg/kg/24 h IV in 1–2 doses; PCP: 15–20 mg/kg IV or PO (TMP) in 4 doses; Nocardia: 10–15 mg/kg IV fr PO (TMP) in 4 doses; IV, prophylactic; 1 g PO SID.
W/P: [C (D if near term), —].
CI: —.
SE: —.

TRIHYDROXALIC ACID, SULFUR 
USES: Synergistic action, interacts w/ warfarin.
ACTIONS: Synergistic combo, interacts w/ warfarin.
DOSE: All doses based on TMP.
W/P: [C (D if near term), —].
SE: —.

VALACYCLOVIR (VALTREX, GENERIC)
USES: VZV, herpes zoster, genital herpes, herpes labialis.
DOSE: Zostavax: 1 g PO TID × 3 days. Genvar/Apovir (initial episode): 1 g BD × 7–10 days; Recurrence: 500 mg PO BID × 3 days. Herpes prophylaxis: 500–1,000 mg/d. Herpes labialis: 2 g PO q2h × 1 day w/ renal failure.
W/P: [B, ±] CYP3A4 effects in elderly.
DISP: Caps 500, 1,000 mg. Tab 500, 1,000 mg.
SE: Headache, GI upset, ↑ LFTs, dizziness, pruritus, photophobia.

VALMISURON (VALSTAR)
USES: Intravenous therapy of BCG refractory bladder CIS in patients for whom immediate cystectomy would be associated with unacceptable morbidity or mortality.
ACTIONS: An anthracycline, alkylating agent.
DOSE: 500 mg intravenously 1 wk for 6 wk (4 wk shrinkage in 55 mg/d, total volume of 75 mL).
W/P: [C] — do not administer w/ perfusion-related bladder.
CI: Hypersensitivity to anthracyclines or piperazine castor oil, U/I, bladder capacity > 75 mL.
DISP: 5 mL single-use vials (200 mg/mL).
SE: Frequency, dysuria, urgency, spasm, hematuria, pain, incontinence.
NOTES: Monitor closely for disease recurrence or progression; if there is not a complete response of CIS to treatment after 3 mo or if CIS recurs, cystectomy must be reconsidered. Procedures for proper handling and disposal of antitumor drugs should be used. Spills should be cleaned up w/ unlabeled chlorine bleach.

VANCOMYCIN (VANCOCIN, GENERIC)
USES: Serious MMA infections, Enterococcal infections; PO treat of S. aureus and C. difficile pseudomembranous colitis.
ACTIONS: Synthetase inhibitors.
DOSE: 20 mg PO BID; 60 mg ER caps PO daily a.m., 1 hr ac or on empty stomach. ↓ w/ CrCl <30 ml/min in elderly.
W/P: [C, ±, —] w/ ESR use, in hot environments, ulcerative colitis, myasthenia gravis, renal/hepatic impairment.
CI: Slower gastric retention, narrow-angle glaucoma.
DISP: Tabs 20 mg. Caps 80–60 mg.
SE: Dry mouth, constipation, headache, rash.

VANCOYMYCIN (VANCOCIN, GENERIC)
USES: S. aureus w/ or w/o endocarditis, infection, meningitis.
ACTIONS: Muscarinic antagonist. ↓ bladder smooth muscle tone.
DOSE: 20 mg PO SID; 60 mg ER caps PO daily a.m., 1 hr ac or on empty stomach. ↓ w/ CCl <30 ml/min in elderly.
W/P: [C, ±, —] w/ ESR use, in hot environments, ulcerative colitis, myasthenia gravis, renal/hepatic impairment.
CI: Slower gastric retention, narrow-angle glaucoma.
DISP: Tabs 20 mg. Caps 80–60 mg.
SE: Dry mouth, constipation, headache, rash.

VANOCOYMYCIN (VANCOCIN, GENERIC)
USES: S. aureus w/ or w/o endocarditis, infection, meningitis.
ACTIONS: Muscarinic antagonist. ↓ bladder smooth muscle tone.
DOSE: 20 mg PO SID; 60 mg ER caps PO daily a.m., 1 hr ac or on empty stomach. ↓ w/ CCl <30 ml/min in elderly.
W/P: [C, ±, —] w/ ESR use, in hot environments, ulcerative colitis, myasthenia gravis, renal/hepatic impairment.
CI: Slower gastric retention, narrow-angle glaucoma.
DISP: Tabs 20 mg. Caps 80–60 mg.
SE: Dry mouth, constipation, headache, rash.

VANOCOYMYCIN (VANCOCIN, GENERIC)
USES: S. aureus w/ or w/o endocarditis, infection, meningitis.
ACTIONS: Muscarinic antagonist. ↓ bladder smooth muscle tone.
DOSE: 20 mg PO SID; 60 mg ER caps PO daily a.m., 1 hr ac or on empty stomach. ↓ w/ CCl <30 ml/min in elderly.
W/P: [C, ±, —] w/ ESR use, in hot environments, ulcerative colitis, myasthenia gravis, renal/hepatic impairment.
CI: Slower gastric retention, narrow-angle glaucoma.
DISP: Tabs 20 mg. Caps 80–60 mg.
SE: Dry mouth, constipation, headache, rash.
VARDENAFIL (LEVITRA, STAXYN, GENERIC)

**USE:** Erectile dysfunction.

**DOSE:** PO: 10 mg, 20 mg, 40 mg; PDE5 inhibitor, increases cGMP and NO.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNING:** Can cause major/fatal bleeding.

**USES:** Prophylaxis & Treat of PE & DVT, AF w/ embolization, other postop indications.

**DOSAGE:** PO: 5 mg, 10 mg, 20 mg; 2.5 mg w/ CV, hepatic, or renal disease or if sex not rec (toxic > μg dose; use w/ caution in patients with bleeding risk). Remember: If you stop the drug, the effect is permanent.

**NOTES:** Monitor vit K intake; use w/ caution in patients w/ bleeding risk.

**VINCRISTINE (MARQIBO, GENERIC)

**USE:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**DOSE:** IV: 1–5 mg/m²; IV over 1 hr or continuous infusion (1 mg/min). Inhibited by: Barbiturates, carbamazepine, cholestyramine, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.

**WARNINGS:** Can cause major/fatal bleeding.

**USES:** Hodgkin’s disease, non-Hodgkin’s malignant lymphomas, thymomas, neuroblastomas, Wilms’ tumor, acute leukemia.

**ACTIONS:** Promotes disassembly of mitotic spindle, causing metaphase arrest, early exit.
ZALEDRONIC ACID (RECLAST, ZOMETA, GENERIC)

USES:
- Hypercalcemia of malignancy (HCM), skeletal-related events in community-acquired pneumonia, multiple myeloma, & metastatic bone lesions (Zometasetm); treatment/radiation dose of postmenopausal osteoporosis, Paget disease, bone mass in men w/ osteoporosis,人事-induced osteoporosis (RDI).

ACTIONS:
- Bisphosphonate; ↓ osteoclastic bone resorption.

DOSE: Zometa: HCM: 4 mg IV q 24 hrs; may retreat in 7 days w/ adequate renal function. Postmenopausal osteoporosis: 5 mg IV q 4 wk; Paget: 5 mg IV x 1.

W/P: [ ]; w/ Olcegepant, angioedema; ASA-sensitive asthmatics; avoid invasive dental procedures.

NOTES: Requires vigorous prehydration; do not exceed 30 minutes of infusion; give Ca²⁺- and vit D sups; may ↓ atypical subtrochanteric femur fractures.

Cytochrome P-450 enzymes and common medication interactions

CYP1A2
- Substrates: Acetaminophen, caffeine, cyclobenzaprine, clonazepam, imipramine, medazepam, nisoldipine, phenobarbital, theophylline
- Inhibitors: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, fluvoxamine, ketonazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Most NSAIDs (including COX-2), glipizide, thiabendazole, indinavir, tamoxifen, warfarin

CYP2A6
- Substrates: Aripiprazole, clozapine, haloperidol, risperidone, thioridazine

CYP2C9
- Substrates: Carvedilol, metoprolol, propafenone, tamsulosin

CYP2C19
- Substrates: Aripiprazole, clozapine, haloperidol, risperidone, thioridazine

CYP3A
- Substrates: Ketoconazole, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2D6
- Substrates: Aripiprazole, clozapine, haloperidol, risperidone, thioridazine

CYP2D6
- Substrates: Aripiprazole, clozapine, haloperidol, risperidone, thioridazine

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, fluvoxamine, ketonazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,
- Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, midazolam, smoking

CYP2C19
- Substrates: Amiodarone, clarithromycin, diltiazem, erythromycin, fluconazole, grapefruit juice (in high ingestion), indinavir, itraconazole, ketocnazole, nefazodone, nefazodone, nelfi,

Antibiotic Prophylaxis: AUA Guidelines

Patients undergoing urologic surgery should be considered for appropriate antibiotic prophylaxis. The American Urological Association (AUA) has made the following recommendations to help with decisions regarding use of antimicrobial prophylaxis in urologic surgery based on upper or lower urinary tract surgery. The selection of agent and determination of appropriate dosage should always consider the patient's specific circumstances (e.g., age, etc.).

Key points in the AUA guidelines:

- The duration of surgical prophylaxis should extend throughout the period in which bacterial invasion is facilitated and/or is likely to establish an infection.
- Begin infusion of the 1st dose within 60 minutes of the incision (except 120 min for IV fluoroquinolones and vancomycin).
- Do not extend prophylaxis beyond 24 h after a procedure except with prophylactic materials, if a urinary catheter is present prior to or is placed at the time of the procedure in patients with risk factors, or in the presence of documented bacteriuria.
- For surgical prophylaxis, all agents should be administered IV (except for oral medications for fluorquinolones,trimethoprim-sulfamethoxazole, bowel preparation agents, and some agents given at catheter removal); in addition, intramuscular administration for antimicrobials for transurethral prostate biopsy is acceptable.
- With an existing infection, a therapeutic course of antimicrobials should be given in an attempt to sterilize the field or suppress the bacterial count.
- Prophylaxis can be omitted if urine culture shows no growth.
- Standard dosing regimens are noted. Dose adjustments based on body weight. Additional intraoperative doses are required intraoperatively if the procedure extends beyond 2 half-lives of the initial dose.
- Use agents with appropriate post-procedure endogenous/exogenous material, distant coexistent infection, prolonged hospitalization.

The duration of surgical prophylaxis should extend throughout the period in which bacterial invasion is facilitated and/or is likely to establish an infection.

- Begin infusion of the 1st dose within 60 minutes of the incision (except 120 min for IV fluoroquinolones and vancomycin).
- Do not extend prophylaxis beyond 24 h after a procedure except with prophylactic materials, if a urinary catheter is present prior to or is placed at the time of the procedure in patients with risk factors, or in the presence of documented bacteriuria.

Anticoagulation and Antiplatelet Therapy in Urologic Practice

The following is based on Anticoagulation and Antiplatelet Therapy in Urologic Practice: ICUD and AUA Review Paper. The American Urologic Association (AUA) and the International Consultation on Urological Disease (ICUD) collaborated on this review.

Patients often have multiple comorbidities and require urologic surgical intervention. Conditions can include coronary arterial disease requiring percutaneous coronary artery intervention with angioplasty, bare metal coronary stents, drug eluting coronary stent, cardiac dysrhythmias (such as atrial fibrillation, others), valvular heart disease, deep venous thrombosis, and inferior vena cava filters. This table provides guidelines on the management of anticoagulation and antiplatelet (AP) therapy in urologic practice. These are only general guidelines with the most effective approach for an individual patient best determined by the patient’s clinical conditions and in collaboration with a multidisciplinary medical team that may include internists, cardiologists, or neurologists where appropriate.

- **Anticoagulant (AC)**
  - Heparins
  - Warfarin
  - New oral anticoagulants (NOACs) include thrombin inhibitor, dabigatran, and the factor Xa inhibitors, rivaroxaban, and apixaban

- **Oral Anti Platelet (AP)**
  - AP medications: aspirin, clopidogrel, ticagrelor, ticlopidine, dipyridamole

1. **Deep venous thrombosis and pulmonary embolism** are discussed in Section I: “Deep Venous Thrombosis and Pulmonary Embolus, Urologic Considerations” and Section II: “Deep Venous Thrombosis, Prophylaxis, AUA Guidelines.”

2. For patients on clopidogrel or aspirin for secondary stroke prevention: continue aspirin through the perioperative period.

3. **Coronary artery stents:** Dual AP therapy should not be stopped before urologic surgery within 12 mo of drug eluding stent or within 3 mo of a bare metal stent. For urologic procedures outside of these limits discontinuation of the clop idogrel, prasugrel, or ticagrelor, and continuation of aspirin, is recommended if procedural bleeding risks are acceptable.

4. **Mechanical heart valves:** AC bridge therapy is recommended.

5. **Cardiac risk factors on low-dose aspirin monotherapy:** continue in perioperative period without increased risk of major bleeding.

6. **Low-dose aspirin without specific indication:** may be scheduled electively, discontinuing the aspirin until directed by the team.

7. **Patients on NOACs (apixaban, dabigatran, rivaroxaban), with nonvalvular atrial fibrillation should be risk stratified:**
   - **Minor bleeding risk:** these agents do not have to be modified, similar to the management with warfarin or low-molecular-weight heparin.
   - **Urgent procedure:** delay for 24–36 hr and obtain consultation.
   - **Emergency procedure:** if bleeding risk increased, expert consultation and avoid spinal/epidural anesthesia.
   - **With operative loss of nephrons** determine renal function post-op and adjust these agents.

8. **Atrial fibrillation in high-risk procedure:** stop warfarin 5 days before surgery; restart 12–24 hr post-op if bleeding risk acceptable.

9. **Higher risk of thromboembolic events (eg, mechanical valves) on warfarin:** bridging anticoagulation with unfractionated heparin or low-molecular-weight heparin. The NOACs apixaban, dabigatran, or rivaroxaban, would be stopped 3–5 days before elective surgery based on the bleeding risk of the procedure. Rivaroxaban may increase stroke risk if stopped; bridging with some other AC such as heparin is recommended.
Anticoagulation and Antiplatelet Therapy in Urologic Practice (continued)

10. **Prosthetic heart valves:** follow standard guidelines (ie, the American College of Cardiology, American Heart Association, etc.):
   - **Low risk of thrombosis:** bileaflet mechanical AVR and no risk factors (eg, atrial fib, previous thromboembolism, left ventricular dysfunction, hypercoagulable conditions, older generation thrombogenic valves, mechanical tricuspid valves or more than one mechanical valve). Stop warfarin 48–72 hr pre-op and restarted within 24 hr post-op. Heparin is usually unnecessary. Check INR immediately pre-op to ensure that the INR is >1.5.
   - **High risk of thrombosis:** (any mechanical mitral valve replacement or a mechanical aortic valve with any risk factor [see above for risk factors]) begin bridging when the INR <2 (usually 48 hr pre-op): dose adjust aPTT 2–3 times the control. Unfractionated heparin is stopped 4–6 hours pre-op and restarted post-op based on bleeding stability. Restart warfarin as soon as possible postoperatively; unfractionated heparin is continued until the INR is therapeutic for at least 48 hr.

11. **Bridging regimens:** As recommended by the American College of Chest Physicians:
   - A high-dose (therapeutic-dose) heparin bridging (eg, LMW heparin: enoxaparin 1 mg/kg BID or 1.5 mg/kg daily, dalteparin 100 IU/kg BID or 200 IU/kg daily, tinzaparin 175 IU/kg daily, or IV unfractionated heparin to keep aPTT 1.5–2 times control).
   - A low-dose (prophylactic-dose) heparin regimen (eg, enoxaparin 30 mg BID or 40 mg daily, dalteparin 5,000 IU daily, unfractionated Heparin 5,000–7,500 IU BID).
   - An intermediate-dose regimen (eg, enoxaparin 40 mg BID).

12. **ESWL:** oral ACs and APs agents should be stopped and or reversed. Coordinate with multidisciplinary team.

13. **Ureteroscopy:** can be performed with continuing oral ACs and APs agents.

14. **Percutaneous nephrolithotomy (PCNL):** oral ACs and APs agents discontinued prior to PCNL and patients bridged where deemed necessary.

15. **Laser prostatectomy:** In appropriately selected patients can be safely accomplished with a therapeutic INR who has a significant risk of thrombosis without stopping oral ACs and APs agents.

16. **Standard electro surgical TURP:** The use of oral ACs and APs agents in patients undergoing TURP is associated with an increased risk of bleeding. Anticoagulation should be carefully assessed and managed; alternative treatment of the bladder outlet may be preferable.

17. **Prostate biopsy:** safe on low-dose aspirin. With oral ACs small studies suggest this can be performed without significant major bleeding risk. Stopping APs agents before biopsy, when medical evaluation demonstrates a low risk of thromboembolic complications, is associated with a lower rate of minor complications.

18. **Perioperative continuation of aspirin:** this may be associated with a minor risk of increased bleeding, but the transfusion rate is not increased and the consequences of bleeding are minor. The exception is with transurethral resection of the prostate.

SCORE: (0-35)

The International Prostate Symptom Score (IPSS) uses the same 7 questions as the AUA Symptom Index, but adds a “Disease Specific Quality of Life Question” (sometimes referred to as the “bother score”) and scored on a scale from 0 to 6 points (“delighted” to “terrible”).

If you were to spend the rest of your life with your urinary condition just the way it is now, how would you feel about that?

### Contrast Agents, Genitourinary

Contrast agents used in urology include intravascular (CT, excretory urography, vascular studies, etc.), gastrointestinal (oral contrast), body cavity (histogram and tube studies), uroradiological (cystogram, urethrogram, retrograde pyelography, etc.), and MRI contrast agents (gadolinium-based paramagnetic compounds). Commonly used intravascular and uroradiological agents are shown in the tables below. See also Section I: “Contrast Allergy and Reactions” and Section II: “Contrast Induced Nephropathy (CIN)” and “Nephrogenic Systemic Fibrosis/Fibrosing Dermatopathy (NSF/NFD).”

Key points:
- Intravascular contrast agents are classified as ionic or nonionic and high, low, or iso-osmolar relative to serum (290 mOsm/kg H2O).
- High-osmolar contrast media (HOCM) are the oldest intravascular agents and ionize in solution (osmolality typically >1,000). Low-osmolar contrast media (LOCM) and iso-osmolar contrast media (IOCM) are nonionic compounds (no ionization in solution). The toxicity of contrast agents generally decreases as osmolality approaches that of serum. Typical osmolality (in mOsm/kg H2O) is as follows: HOCM > 1,000, LOCM ~ 400–800, and IOCM 290.
- Uroradiologic contrast agents are not injected into the circulation so that issues relating to potential toxicity are almost nonexistent.
- MRI contrast agents: Nephrogenic systemic fibrosis (NSF) is associated with the administration of intravenous gadolinium. The primary risk factor is renal insufficiency (dialysis patient or with a GFR < 30).

#### Intravascular Contrast Agents

Agents sorted by osmolarity from highest to lowest and represent commonly used agents in the United States.

INTERNATIONAL INDEX OF ERECTILE FUNCTION (IIEF) 
Patient Questionnaire 

These questions ask about the effects that your erection problems have had on your sex life over the last four weeks. Please try to answer the questions as honestly and as clearly as you are able. Your answers will help your doctor to choose the most effective treatment suited to your condition. In answering the questions, the following definitions apply:

- **Sexual activity** includes intercourse, caressing, foreplay, and masturbation
- **Sexual intercourse** is defined as sexual penetration of your partner
- **Sexual stimulation** includes situation such as foreplay, erotic pictures etc.
- **Ejaculation** is the ejection of semen from the penis (or the feeling of this)
- **Orgasm** is the fulfillment or climax following sexual stimulation or intercourse

**Over the past 4 weeks:**

<table>
<thead>
<tr>
<th>Question</th>
<th>Please check one box only</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q1 How often were you able to get an erection during sexual activity?</td>
<td></td>
</tr>
<tr>
<td>Q2 When you had erections with sexual stimulation, how often were your erections hard enough for penetration?</td>
<td></td>
</tr>
<tr>
<td>Q3 When you attempted intercourse, how often were you able to penetrate (enter) your partner?</td>
<td></td>
</tr>
<tr>
<td>Q4 During sexual intercourse, how often were you able to maintain your erection after you had penetrated (entered) your partner?</td>
<td></td>
</tr>
<tr>
<td>Q5 During sexual intercourse, how difficult was it to maintain your erection to completion of intercourse?</td>
<td></td>
</tr>
<tr>
<td>Q6 How many times have you attempted sexual intercourse?</td>
<td></td>
</tr>
<tr>
<td>Q7 When you attempted sexual intercourse, how often was it satisfactory for you?</td>
<td></td>
</tr>
<tr>
<td>Q8 How much have you enjoyed sexual intercourse?</td>
<td></td>
</tr>
<tr>
<td>Q9 When you had sexual stimulation or intercourse, how often did you ejaculate?</td>
<td></td>
</tr>
</tbody>
</table>

(Continued on next page)
Q10 When you had sexual stimulation or intercourse, how often did you have the feeling of orgasm or climax?

1. Almost never or never
2. A few times (less than half the time)
3. Sometimes (about half the time)
4. Most times (more than half the time)
5. Almost always or always

Q11 How often have you felt sexual desire?

1. Almost never or never
2. A few times (less than half the time)
3. Sometimes (about half the time)
4. Most times (more than half the time)
5. Almost always or always

Q12 How would you rate your level of sexual desire?

1. Very low or none at all
2. Low
3. Moderate
4. High
5. Very high

Q13 How satisfied have you been with your overall sex life?

1. Very dissatisfied
2. Moderately dissatisfied
3. Equally satisfied and dissatisfied
4. Moderately satisfied
5. Very satisfied

Q14 How satisfied have you been with your sexual relationship with your partner?

1. Very dissatisfied
2. Moderately dissatisfied
3. Equally satisfied & dissatisfied
4. Moderately satisfied
5. Very satisfied

Q15 How do you rate your confidence that you could get and keep an erection?

1. Very low
2. Low
3. Moderate
4. High
5. Very high

Total Score ___________

Interpretation of IIEF

<table>
<thead>
<tr>
<th>IIEF Domains</th>
<th>Maximum Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. Erectile Function (Questions 1, 2, 3, 4, 5, 15)</td>
<td>30</td>
</tr>
<tr>
<td>B. Orgasmic Function (Questions 9, 10)</td>
<td>10</td>
</tr>
<tr>

<td>15</td>
</tr>
<tr>
<td>E. Overall Satisfaction (Questions 13, 14)</td>
<td>10</td>
</tr>
</tbody>
</table>

A score of 0–5 is awarded to each of the 15 questions that examine the 4 main domains of male sexual function: erectile function, orgasmic function, sexual desire, and intercourse satisfaction.

Analysis of the questionnaire should, therefore, be viewed as an adjunct to, rather than a substitute for, a detailed sexual history and examination. The following guidelines are typical based on the IIEF scores and are based on the recommendations of the British Association of Urologic Surgeons:

1. Low IIEF scores (<14 out of 30) in Domain A (Erectile Function) may be considered for a trial course of therapy with Sildenafil unless contraindicated. Specialist referral is indicated if this is unsuccessful.
2. Patients demonstrating primary orgasmic or ejaculatory dysfunction (Domain B) should be referred for specialist investigation.
3. Patients with reduced sexual desire (Domain C) require testing of blood levels of androgen and prolactin.
4. Psychosexual counselling should be considered if low scores are recorded in Domains D and E but there is only a moderately lowered score (14 to 25) in Domain A.

Male Sexual Health Questionnaire (MSHQ) Short Form

A modified form, known as the MSHQ Short Form is commonly used for assessing ejaculatory dysfunction (also called the MSHQ-EjD). See also Section II: Male Sexual Health Questionnaire (MSHQ) and the MSHQ short form.

In the past month:

National Institutes of Health (NIH) Chronic Prostatitis Symptom Index (CPSI)
(See also Section II: National Institutes of Health (NIH) Chronic Prostatitis Symptom Index. Form is to be filled out by patient.)

Pain or Discomfort
1. In the last week, have you experienced any pain or discomfort in the following areas?
   - Area between rectum and testicles (perineum) [Yes] [No]
   - Testicles [Yes] [No]
   - Tip of the penis (related to urination) [Yes] [No]
   - Below your waist, in your pubic or bladder area [Yes] [No]

2. In the last week, have you experienced:
   - Pain or burning during urination [Yes] [No]
   - Pain discomfort during or after sexual climax (ejaculation) [Yes] [No]

3. How often have you had pain or discomfort in any of these areas over the last week?
   - Never [ ]
   - Rarely [ ]
   - Sometimes [ ]
   - Often [ ]
   - Usually [ ]
   - Always [ ]

4. Which number best describes your AVERAGE pain or discomfort on the days that you had it, over the last week?
   0 = Not at all
   1 = Less than 1 time in 5
   2 = Less than half the time
   3 = About half the time
   4 = More than half the time
   5 = Almost always

5. How often have you had a sensation of not emptying your bladder completely after you finished urinating, over the last week?
   - Not at all [ ]
   - Only a little [ ]
   - Some [ ]
   - A lot [ ]

6. How often have you had to urinate again less than two hours after you finished urinating, over the last week?
   - Not at all [ ]
   - Less than 1 time in 5 [ ]
   - Less than half the time [ ]
   - About half the time [ ]
   - More than half the time [ ]
   - Almost always [ ]

Impact of Symptoms
7. How much have your symptoms kept you from doing the kinds of things you would usually do, over the last week?
   - None [ ]
   - Only a little [ ]
   - Some [ ]
   - A lot [ ]

Quality of Life
8. How much did you think about your symptoms, over the last weeks?
   - None [ ]
   - Only a little [ ]
   - Some [ ]
   - A lot [ ]

Scoring the NIH-Chronic Prostatitis Symptom Index Domains
Pain: Total of items 1a, 1b, 1c, 1d, 2a, 2b, 3, and 4 =___________
Urinary Symptoms: Total of items 5 and 6 =___________
Quality of Life Impact: Total of items 7, 8, and 9 =___________

Prostate Cancer Screening Guidelines

Screening for prostate cancer is highly controversial. This table summarizes some of the major US and international medical groups recommendations in this area.

<table>
<thead>
<tr>
<th>Organization (Year)</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>American Cancer Society (ACS)</strong> (2010)</td>
<td>1. No routine screening; after informed discussion of risk and benefits for those who wish to be screened 2. No screening with &lt;10-yr life expectancy 3. Screen with PSA, w/ or w/o DRE, at age 50 with &gt;10 yr life expectancy; if PSA &gt;2.5 ng/mL, screen yearly, otherwise screen every 2 yr 4. Beginning screening discussions at age 40-45 if at high risk of developing prostate cancer (eg, black man, or with a first-degree relative with prostate cancer diagnosed before age 65). 5. Biopsy referral threshold is 4 ng/mL. With PSA 2.5-4 ng/mL, encourage individualized decision making and assessment (<a href="http://deb.uthscsa.edu/URORiskCalc/Pages/uroriskcalc.jsp">http://deb.uthscsa.edu/URORiskCalc/Pages/uroriskcalc.jsp</a>), which can include age, race, family history, DRE, previous biopsy results, and use of 5α-reductase inhibitors.</td>
</tr>
<tr>
<td><strong>American College of Physicians</strong> (2013)</td>
<td>1. Inform men age 50-69 about limited benefits and harms; screen only if patient wants it 2. Do not screen &lt;age 50 if average risk, over 69, or &lt;10-15-yr life expectancy</td>
</tr>
<tr>
<td><strong>American Urological Association</strong> (2013)</td>
<td>1. No screening under 40; not recommended if average risk 40-54; individualize if high risk* 2. Shared decision making for men age 55-69 3. No screening over age 75 or any man &lt;10-15-yr life expectancy some men over age 70 in excellent health might benefit from screening. 4. Reduce the harms of screening, a screening interval of 2 yr or more may be preferred. 5. Lack of evidence for using any tests (eg, PSA derivatives, PSA kinetics, PSA molecular markers, urinary markers, imaging, or risk calculators) other than PSA for triggering a biopsy referral. 6. No specific threshold for biopsy referral.</td>
</tr>
<tr>
<td><strong>Australian Cancer Council (2011)</strong></td>
<td>1. Does not support population-based screening 2. Recommends a patient-centered approach that individualizes the decision</td>
</tr>
<tr>
<td><strong>Canadian Task Force on Preventive Health Care (2006; 2014 Update pending)</strong></td>
<td>1. Recommends against screening for prostate cancer with PSA or TRUS 2. Insufficient evidence to recommend for or against screening with DRE</td>
</tr>
<tr>
<td><strong>European Society for Medical Oncology (ESMO)</strong> (2013)</td>
<td>1. Recommends against population-based screening; favors individualized shared decision making 2. There is inconsistent evidence screening men &lt;55 and 70-75 yr of age; evidence that the harms of screening outweigh the benefits for men over age 75.</td>
</tr>
<tr>
<td><strong>National Comprehensive Cancer Network (NCCN)</strong> (2014)</td>
<td>1. Informed discussion with all 2. Baseline DRE and PSA age 45; if PSA &lt;1, repeat every age 50; if PSA &gt;1, repeat every 1-2 yr 3. Age 50-70 with normal DRE and PSA &lt;3, repeat every 1-2 yr 4. Use caution screening if &gt; age 70 and only if very healthy; few &gt; age 75 benefit from screening</td>
</tr>
<tr>
<td><strong>United Kingdom National Screening Committee (2010)</strong></td>
<td>1. Does not recommend screening for prostate cancer</td>
</tr>
<tr>
<td><strong>United States Preventive Services Task Force (USPSTF)</strong> (2012)</td>
<td>1. No role in any man unless symptoms (grade D) 2. Men requesting screening be supported in making an informed decision.</td>
</tr>
</tbody>
</table>

All PSA values are ng/mL
* African American or have a 1st-degree relative diagnosed with PCa at <65 yr of age.
* Several 1st-degree relatives diagnosed with PCa at <65 yr of age.
* Positive family history or African American race.

SEXUAL HEALTH INVENTORY FOR MEN
IIEF-5

PATIENT INSTRUCTIONS
Sexual health is an important part of an individual’s overall physical and emotional well-being. Erectile dysfunction is one type of very common sexual complaint. There are many different treatment options for erectile dysfunction. This questionnaire is designed to help you and your physician identify if you may be experiencing erectile dysfunction and to potentially discuss treatment options.

Each question has several responses from which you are asked to choose the one that best describes your own situation. Please be sure that you select at least one but only one response by circling the number that best fits your answer.

Over the past six months:

Score:_____

If your score is 21 or less, you show signs of erectile dysfunction, and your doctor can suggest treatment options that can improve your condition.

Sexual Health Inventory for Men. An abridged 5-item version of the 15-item International Index of Erectile Function (IIEF-5) was developed to diagnose the presence and severity of erectile dysfunction (ED). Reprinted with permission from Rosen RC, Cappelleri JC, Smith MD, Lipsky J, Peria BM. Development and evaluation of an abridged, 5-item version of the International Index of Erectile Function (IIEF-5) as a diagnostic tool for erectile dysfunction. Int J Impot Res. 1999;11:319–326.
**TNM Classification: Cervix Cancer**

**DEFINITION OF TNM**

**T1**
- Cervical carcinoma confined to uterus (T1a) Invasive carcinoma diagnosed only by microscopy. Stromal invasion with a maximum depth of 5 mm measured from the base of the epithelium and a horizontal spread of ≤7 mm. Vascular space involvement, venous or lymphatic, does not affect classification. (T1a1) Measured stromal invasion ≤3 mm in depth and ≤7 mm in horizontal spread (T1a2) Measured stromal invasion >3 mm and not >5 mm with a horizontal spread ≤7 mm

**IA1/A2**
- IA1: Clinically visible lesion confined to cervix or microscopic lesion greater than T1a/IA2 (T1b1) Clinically visible lesion >4 cm in greatest dimension (T1b2) Clinically visible lesion >4 cm in greatest dimension
- A2: No regional lymph node metastasis

**IB1/B2**
- IB1: Clinically visible lesion confined to cervix or microscopic lesion greater than T1a/IA2 (T1b1) Clinically visible lesion >4 cm in greatest dimension (T1b2) Clinically visible lesion >4 cm in greatest dimension
- B2: No regional lymph node metastasis

**IIB**
- IIB: Clinically visible lesion confined to the cervix or microscopic lesion greater than T1a/IA2 (T1b1) Clinically visible lesion >4 cm in greatest dimension (T1b2) Clinically visible lesion >4 cm in greatest dimension
- B2: No regional lymph node metastasis

**IIIA**
- Tumor extends to pelvic wall and/or involves lower third of vagina, and/or causes hydronephrosis or nonfunctioning kidney (T3a) Tumor involves lower third of vagina, no extension to pelvic wall (T3b) Tumor extends to pelvic wall and/or causes hydronephrosis or nonfunctioning kidney
- N1: Regional lymph node metastasis

**IIIB**
- T4: Tumor invades mucosa of bladder or rectum, and/or extends beyond true pelvis (bulbous edema is not sufficient to classify a tumor as T4)
- M0: No distant metastasis

**IVA**
- M1: Distant metastasis (including peritoneal spread, involvement of supraclavicular, mediastinal, or paraaortic lymph nodes, lung, liver, or bone)

**IVB**
- M1: Any T, Any N, M1

**TNM Classification: Colon Cancer**

**DEFINITION OF TNM**

- **T1**: Tumor invades submucosa
- **T2**: Tumor invades muscularis propria
- **T3**: Tumor invades through the muscularis propria into perirectal tissues
- **T4**: Tumor directly invades other organs or structures, and/or perforates visceral peritoneum

- **N0**: No regional lymph node metastasis
- **N1a**: Metastasis in 1 regional lymph node
- **N1b**: Metastasis in 2–3 regional lymph nodes
- **N1c**: Tumor deposit(s) in the subserosa, mesentery, or nonperitonealized paricolic or pararectal tissues without regional nodal metastasis
- **N2a**: Metastasis in 4–6 regional lymph nodes
- **N2b**: Metastasis in 7 or more regional lymph nodes

- **M1a**: Metastasis confined to 1 organ or site (eg, liver, lung, ovary, nonregional node)
- **M1b**: Metastases in more than 1 organ/site or the peritoneum

**STAGE GROUPINGS**

- **Stage I**
  - **T1 N0 M0**
  - **T2 N0 M0**

- **Stage II**
  - **T3 N0 M0**
  - **T4 N0 M0**

- **Stage III**
  - **T3 N1 M0**
  - **T2 N2a M0**

- **Stage IV**
  - **Any T Any N M1a**
  - **Any T Any N M1b**

**Stage IIIA**

- **T1–T2 N1a–N1c M0**
- **T1 N2a M0**

**Stage IIIB**

- **T3 T4a N1a–N1c M0**
- **T2 T3 N2a M0**
- **T1 T2 N2b M0**

**Stage IIIC**

- **T4b N0 M0**

**Stage IVA**

- **Any T Any N M1a**

**Stage IVB**

- **Any T Any N M1b**

---

*Note: Tumor directly invades or is adherent to other organs or structures, and/or perforates visceral peritoneum include invasion of other organs or other segments of the colorectum as a result of direct extension through the serosa, as confirmed on microscopic examination (eg, invasion of the sigmoid colon by a carcinoma of the cecum or, for cancers in a retroperitoneal or subperitoneal location, direct invasion of other organs or structures by virtue of extension beyond the muscularis propria). Invasion of the sigmoid colon by a carcinoma of the cecum or colon, for example, is classified as Dukes’ A1, whereas invasion of an adjacent organ (eg, bladder, ovary, other pelvic organ) by direct extension (without perforation of the visera) is classified as T4a. Invasion of the sigmoid colon by a carcinoma of the cecum or colon, for example, is classified as Dukes’ A1, whereas invasion of an adjacent organ (eg, bladder, ovary, other pelvic organ) by direct extension (without perforation of the visera) is classified as T4a. The V and L classifications should be used to identify the presence or absence of vascular or lymphatic invasion, whereas the PN site-specific factor should be used for perineural invasion.*

---

TNM Classification: Kidney Cancer

DEFINITION OF TNM

Stage I
- T1: Tumor ≤ 7 cm in greatest dimension, limited to the kidney
- T1a: Tumor ≤ 4 cm in greatest dimension, limited to the kidney
- T1b: Tumor > 4 cm but not > 7 cm in greatest dimension, limited to the kidney
- N0: No regional lymph node metastasis

Stage II
- T2: Tumor > 7 cm in greatest dimension, limited to the kidney
- T2a: Tumor > 7 cm but ≤ 10 cm in greatest dimension, limited to the kidney
- T2b: Tumor > 10 cm, limited to the kidney
- N0: No regional lymph node metastasis

Stage III
- T3: Tumor extends into major veins or perinephric tissues but not into the ipsilateral adrenal gland and not beyond Gerota’s fascia
- T3a: Tumor grossly extends into the renal vein or its segmental (muscle containing) branches, or tumor invades perirenal and/or renal sinus fat but not beyond Gerota’s fascia
- T3b: Tumor grossly extends into the vena cava below the diaphragm
- T3c: Tumor grossly extends into the vena cava above the diaphragm or invades the wall of the vena cava
- N1: Metastasis in a single regional lymph node

Stage IV
- T4: Tumor invades beyond Gerota’s fascia (including contiguous extension into the ipsilateral adrenal gland)
- M0: No distant metastasis
- M1: Distant metastasis

Stage Groupings

- Stage I: T1 N0 M0
- Stage II: T2 N0 M0
- Stage III: T1 or T2 N1 M0*
- Stage IV: T3 N0 or N1 M0*
- Stage IV: T4 Any N M0*
- Stage IV: Any T Any N M1

* not illustrated

TNM Classification: Penis Cancer

**DEFINITION OF TNM**

- **T1**: Noninvasive verrucous carcinoma
  - T1a: Tumor invades subepithelial connective tissue without lymph vascular invasion and is not poorly differentiated (ie, grade 3–4)
  - T1b: Tumor invades subepithelial connective tissue with lymph vascular invasion or is poorly differentiated
- **cN0**: No palpable or visibly enlarged inguinal lymph nodes
- **cN1**: Palpable mobile unilateral inguinal lymph node

**STAGE GROUPINGS**

- **Stage I**
  - T1a  N0  M0
- **Stage II**
  - T1b  N0  M0
  - T2  N0  M0
- **Stage IIIA**
  - T1a  N1  M0
  - T1b  N1  M0
  - T2  N1  M0
- **Stage IIIB**
  - T1a  N2  M0
  - T1b  N2  M0
  - T2  N2  M0
- **Stage IV**
  - T4       Any N  M0
  - Any T  N3       M0
  - Any T  Any N  M1

*Note: Lymph node metastases outside of the true pelvis in addition to visceral or bone sites.*

TNM Classification: Prostate Cancer

Note: Prostate cancer can be staged clinically (eg: cT1b) or pathologically (eg: pT2b). Pathologic and clinical staging are similar except that there is no pathological T1 stage.

<table>
<thead>
<tr>
<th>TNM Classification: Prostate Cancer</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINITION OF TNM</td>
</tr>
</tbody>
</table>

**Stage I**
- T1: Clinically inapparent tumor neither palpable nor visible by imaging (T1a: Tumor incidental histologic finding in less than 5% of tissue resected; T1b: Tumor incidental histologic finding in more than 5% of tissue resected; T1c: Tumor identified by needle biopsy eg, because of elevated PSA)
- N0: No regional lymph node metastasis
- G1: Well differentiated (Gleason 2-4)

**Stage IIA**
- T2: Tumor confined within prostate* (T2a: Tumor involves one-half of one lobe or less; T2b: Tumor involves more than one-half of one lobe but not both lobes; T2c: Tumor involves both lobes)
- N0: No regional lymph node metastasis
- G2: Moderately differentiated (moderate anaplasia Gleason 5-6)

**Stage IIB**
- T3: Tumor extends through the prostate capsule** (T3a: Extracapsular extension (unilateral or bilateral); T3b: Tumor invades seminal vesicle(s))
- N0: No regional lymph node metastasis
- G3–4: Poorly differentiated/undifferentiated (marked anaplasia Gleason 7-10)

**Stage III**
- T4: Tumor is fixed or invades adjacent structures other than central vessels, muscularis of urethra, bladder, levator muscles, or pelvic wall
- N0: No regional lymph node metastasis
- N1: Metastasis in regional lymph node(s)
- M0: No distant metastasis

**Stage IV**
- M1: Distant metastasis (M1a: Nonregional lymph node(s); M1b: Bone(s); M1c: Other site(s) with or without bone disease)

*Note: when more than 1 site of metastasis is present, the most advanced site category is used (M1c is most advanced).

**Stage 1**
- T1a–c: N0 M0 G1
- T1a: N0 M0 G1
- T1b: N0 M0 G1
- T1c: N0 M0 G1

*Note: Direct invasion in T4 includes invasion of other organs or structures of the colon/rectum as a result of direct extension through the serosa, as confirmed on microscopic examination (for example, invasion of the left colon by a carcinoma of the transverse colon). If invasion is due to spread through lymph nodes (eg, invasion of the left colon by a carcinoma of the cecum), it should be classified T3 or T4a.***

***Note: Tumor that is adherent to other organs or structures, grossly, is classified cT4b. However, if no tumor is present in the adhesion, microscopically, the classification should be pT1–4a depending on the anatomical depth of wall invasion. The V and L classifications should be used to identify the presence or absence of vascular or lymphatic invasion whereas the PN site-specific factor should be used for perineural invasion.***

### TNM Classification: Renal Pelvis and Ureter Cancer

**DEFINITION OF TNM**

**T**
- **T1**: Tumor invades subepithelial connective tissue
- **T2**: Tumor invades the muscularis
- **T3**: (For renal pelvis only) Tumor invades beyond muscularis into peripelvic fat or the renal parenchyma.
- **T4**: Tumor invades adjacent organs, or through the kidney into the perinephric fat

**N**
- **N0**: No regional lymph node metastasis
- **N1**: Metastasis in a single lymph node, ≤2 cm in greatest dimension
- **N2**: Metastasis in a single lymph node, >2 cm but not >5 cm in greatest dimension; or multiple lymph nodes, none >5 cm in greatest dimension
- **N3**: Metastasis in lymph node, >5 cm in greatest dimension

**M**
- **M0**: No distant metastasis
- **M1**: Distant metastasis

---

**TNM Classification: Testis Cancer**

**DEFINITION OF TNM**
- **pT1** - Tumor limited to the testis and epididymis without vascular/lymphatic invasion; tumor may invade into the tunica albuginea but not the tunica vaginalis
- **pT2** - Tumor limited to the testis and epididymis with vascular/lymphatic invasion of tumor extending through the tunica albuginea with involvement of the tunica vaginalis
- **pT3** - Tumor involves the spermatic cord with or without vascular/lymphatic invasion
- **pT4** - Tumor involves the scrotum with or without vascular/lymphatic invasion

TNM Classification: Urethral Cancer

DEFINITION OF TNM

Stage I

T1
Tumor invades subepithelial connective tissue
N0
No regional lymph node metastasis

Stage II

T2
Tumor invades any of the following: corpus spongiosum, prostate, periurethral muscle
N1
Metastasis in a single lymph node ≤ 2 cm in greatest dimension

Stage III

T3
Tumor invades any of the following: corpus cavernosum, beyond prostatic capsule, bladder neck
N1
Metastasis in a single lymph node ≤ 2 cm in greatest dimension

Stage IV

T4
Tumor invades other adjacent structures
N2
Metastasis in a single node more than 2 cm in greatest dimension, or in multiple nodes

Stage IV

M1
Distant metastasis

STAGE GROUPINGS

**TNM Classification: Urinary Bladder Cancer**

**DEFINITION OF TNM**

**T1**
- Tumor invades subepithelial connective tissue
- No regional lymph node metastasis

**T2**
- Tumor invades muscularis propria
- N0: No regional lymph node metastasis

**T3**
- Tumor invades perivesical tissue (pT3a) Microscopically (pT3b) Macroscopically
- N0: No regional lymph node metastasis

**T4**
- Tumor invades any of the following: prostatic stroma, seminal vesicles, uterus, vagina, pelvis wall, abdominal wall
- N1: Single regional lymph node metastasis in the true pelvis (hypogastric, obturator, external iliac, or presacral lymph node)
- N2: Multiple regional lymph node metastasis in the true pelvis (hypogastric, obturator, external iliac, or presacral lymph node metastasis)
- N3: Lymph node metastasis to the common iliac lymph nodes

**N0**
- No regional lymph node metastasis

**M0**
- No distant metastasis

**Uroradiology Signs** (See also Section II: “Uroradiology Signs”)

<table>
<thead>
<tr>
<th>Sign (Typical Modality)</th>
<th>Description</th>
<th>Diagnosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arterial cut-off sign (CT or MRI w/contrast)</td>
<td>Abrupt termination of contrast material within the renal artery</td>
<td>Renal artery obstruction from thrombosis, embolus or dissection from trauma</td>
</tr>
<tr>
<td>Ball-on-Tea, Lobster Claw, signet ring (XR, retrograde urography)</td>
<td>Patterns of renal papillary excavation; signet ring occurs when the necrotic papillary tip remains in the pelvis and then it is filled with contrast material (acts as the “stone” for the ring)</td>
<td>Papillary necrosis (nonsteroidal anti-inflammatory drugs [NSAIDs], sickle cell anemia, analgesic nephropathy, infection-TB, and diabetes mellitus)</td>
</tr>
<tr>
<td>Balloon on a string (XR)</td>
<td>High exit point of ureter from a dilated renal pelvis (can be seen with hydronephrotic rim sign, crescent sign, or on its own)</td>
<td>Ureteropelvic junction obstruction</td>
</tr>
<tr>
<td>Bear’s paw (CT)</td>
<td>Dilated multiloculated appearing renal calyces with contracted renal pelvis (in setting of obstructing stone)</td>
<td>Diffuse xanthogranulomatous pyelonephritis</td>
</tr>
<tr>
<td>Bullet on a Bodkin (XR, CT)</td>
<td>Encasement of the ureter; dilated ureter (the bullet) on top of the smaller encased ureter (the bodkin)</td>
<td>Metastatic disease; extension from an adjacent tumor, lymphoma, or retroperitoneal fibrosis</td>
</tr>
<tr>
<td>Cobra head sign (XR)</td>
<td>Dilatation of the distal ureter that is surrounded by a thin lucent line</td>
<td>Orthotopic ureteroceles</td>
</tr>
<tr>
<td>Codweb (CT)</td>
<td>Exaggerated appearance of perirenal septa</td>
<td>Multiple disease processes but commonly seen in acute ureteral obstruction from stones</td>
</tr>
<tr>
<td>Coiled catheter sign (XR)</td>
<td>Related to goblet sign: Dilated ureteral segment provides a space for catheter to coil within</td>
<td>Urothelial carcinoma</td>
</tr>
<tr>
<td>Comet sign (CT)</td>
<td>Focal density with adjacent, tapering, noncalcified “tail”</td>
<td>Phlebolith</td>
</tr>
<tr>
<td>Concentric ring sign—aka Target sign (MR, best T1 weighted)</td>
<td>Rings of hyper and hypointensity within a hematoma (inner bright ring signifies hemoglobin degradation)</td>
<td>Renal hematoma present for greater than 3 wk</td>
</tr>
<tr>
<td>Corkscrew ureter (XR)</td>
<td>Healing stages of tuberculosis involving the ureter</td>
<td>Late ureteral tuberculosis</td>
</tr>
<tr>
<td>Crescent sign (CT w/contrast)</td>
<td>Concentrated contrast material in collecting tubules, parallel to a dilated calyx</td>
<td>Prolonged, incomplete obstruction of collecting system. (Typically indicates that renal function is still recoverable upon relief of the obstruction)</td>
</tr>
<tr>
<td>Dromedary hump (any modality)</td>
<td>A pseudomass appearing in the left kidney, that is drained by a normal collecting system element</td>
<td>Normal variant of kidney is molded by the adjacent spicula creating a protrusion that can be mistakenly identified as a mass</td>
</tr>
<tr>
<td>Drooping lily sign (XR)</td>
<td>Dilated upper moiety ureter in a duplicated system that places downward and/or lateral pressure on the functional lower moiety</td>
<td>Completely duplicated system with an obstructed upper moiety</td>
</tr>
</tbody>
</table>

Angio, angiography; CT, computed tomography; MRI, magnetic resonance imaging; XR, plain x-ray; IVP or retrograde pyelogram.
**URORADIOLOGY SIGNS (Continued)**

<table>
<thead>
<tr>
<th>Sign (Typical Modality)</th>
<th>Description</th>
<th>Diagnosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Faceless kidney (any modality)</td>
<td>Normal renal parenchyma, lacking central renal sinus structures (duplicated system) or any edema that eliminates the typical appearance of the kidney</td>
<td>Renal duplication (slice in between duplicated systems); edema obliterating normal kidney appearance can signify any inflammatory condition or infiltrative condition such as lymphoma or renal cell carcinoma</td>
</tr>
<tr>
<td>Fragmented staghorn (XR)</td>
<td>Disrupted densities following the outline of the renal pelvis; usually associated with renal enlargement</td>
<td>Pyonephrosis or Xanthogranulomatous pyelonephritis</td>
</tr>
<tr>
<td>Goblet sign (Retrograde XR)</td>
<td>Ureteral dilatation below an intraluminal filling defect; usually a chronic process</td>
<td>Urothelial cell carcinoma; less likely metastatic disease or endometriosis</td>
</tr>
<tr>
<td>Growing calculus sign (XR)</td>
<td>Apparent enlargement of medullary califications contained in acritic tubules pre- and postcontrast administration</td>
<td>Medullary nephrocalcinosis caused by medullary sponge kidney</td>
</tr>
<tr>
<td>Horseshoe</td>
<td>Kidneys joined by a lower pole isthmus that crosses anterior to the aorta, just inferior to the inferior mesenteric artery</td>
<td>Most common congenital fusion abnormality of the kidney (Horseshoe kidney)</td>
</tr>
<tr>
<td>Hydronephrotic rim sign (CT or MR w/contrast)</td>
<td>Variable enhancement of residual but atrophic renal parenchyma surrounding dilated renal pelvis and calyces (inner margin of rim is concave toward hilum, can also have enhancement of cortical columns)</td>
<td>Chronic hydronephrosis</td>
</tr>
<tr>
<td>Keyhole sign (US)</td>
<td>Thick bladder wall and dilated posterior urethra</td>
<td>Posterior urethral valves</td>
</tr>
<tr>
<td>Kidney sweat (US, CT, MR)</td>
<td>Extracapsular hypoechoic rim of fluid around kidney (perirenal edema)</td>
<td>Renal failure</td>
</tr>
<tr>
<td>Loop-to-loop colon</td>
<td>Transverse colon extends lateral to abdominal wall, descending colon then courses medially to fill renal fossa creating a loop of colon</td>
<td>Renal agenesis</td>
</tr>
<tr>
<td>Lying down (pancake) adrenal gland</td>
<td>Typical shape of adrenal gland is dependent on kidney; when kidney absent, the adrenal gland (when present) can assume a flattened appearance</td>
<td>Renal agenesis</td>
</tr>
<tr>
<td>Maiden waist deformity (XR)</td>
<td>Medial deviation of bilateral ureters; ureters are drawn toward each other in the lumbosacral region</td>
<td>Retroperitoneal fibrosis</td>
</tr>
<tr>
<td>Mulberry (XR)</td>
<td>Density in the urinary system with less developed spikes (mamillated appearance)</td>
<td>Calcium oxalate dihydrate stone</td>
</tr>
<tr>
<td>Pear sign (XR, CT)</td>
<td>Symmetric compression of the bladder</td>
<td>Pelvic fluid (hematoma, lymphocele, urinoma, abscess), pelvic hypomacia, vascular distalation from aneurysms or collateral vessels, lymph node enlargement or psoas hypertrophy</td>
</tr>
<tr>
<td>Phantom calyx sign (XR)</td>
<td>No identifiable collecting system element where one should be seen</td>
<td>Inflammation (tuberculosis, acute pyelonephritis), neoplasm, stricture from trauma and/or stone passage, ischemia, congenital anomaly, renal contusion or technical error of underfilling</td>
</tr>
</tbody>
</table>

Angio, angiography; CT, computed tomography; MR, magnetic resonance imaging; XR, plain x-ray; IVP or retrograde pyelogram.
**URORADIOLOGY SIGNS (Continued)**

<table>
<thead>
<tr>
<th>Sign (Typical Modality)</th>
<th>Description</th>
<th>Diagnosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pie-in-the-sky sign (XR)</td>
<td>High position of contrast opacified bladder in pelvis</td>
<td>Pelvic hematoma from pelvic trauma; high suspicion of urethral injury</td>
</tr>
<tr>
<td>Pipestem ureter</td>
<td>Ureter is straight and rigid</td>
<td>Ureteral tuberculosis</td>
</tr>
<tr>
<td>Putty kidney</td>
<td>Calcifications outlining the entire, or close to the entire kidney</td>
<td>Genitourinary tuberculosis (end-stage finding in kidney)</td>
</tr>
<tr>
<td>Reverse rim sign (CT or MR w/contrast)</td>
<td>Hypoattenuating renal cortex with medullary enhancement</td>
<td>Disruption of cortical blood flow with development of cortical necrosis. Can be caused by shock, intravascular hemolysis, toxins, and rejection in transplanted kidney</td>
</tr>
<tr>
<td>Rim sign of vascular compromise (CT or MR w/contrast)</td>
<td>Rim of subcapsular enhancement</td>
<td>Renal artery obstruction from thrombosis, embolus or dissection from trauma (most commonly). Renal vein thrombosis and acute tubular necrosis (less commonly)</td>
</tr>
<tr>
<td>Sawtooth ureter</td>
<td>Dilatation and ragged irregularity of the ureter</td>
<td>Early ureteral tuberculosis</td>
</tr>
<tr>
<td>Soft-tissue rim sign (CT)</td>
<td>Focal density with surrounding edema of ureteral wall</td>
<td>Unilateral stone; usually impacted; may be absent with stones &gt;4 mm or when at UVJ. Can help distinguish stone from phlebolith as it is uncommon for phlebolith to have soft tissue rim</td>
</tr>
<tr>
<td>Spaghetti sign (XR, CT)</td>
<td>Linear filling defect within the bladder</td>
<td>Gross hematuria; this sign implies blood has come from above the bladder (ureter acts as a mold for the blood clot)</td>
</tr>
<tr>
<td>Spoked wheel pattern (US, CT, MR)</td>
<td>Peripheral “rim” vessel branching into centripetal “spoke” vessels within a mass; can have a central area of decreased perfusion (central scar)</td>
<td>Renal cell carcinoma; oncocytoma</td>
</tr>
<tr>
<td>Spotted nephrogram (CT or MR w/contrast, renal angiography)</td>
<td>Patchy irregular enhancement of the renal parenchyma</td>
<td>Small vessel occlusion, caused by scleroderma, hypertensive nephrosclerosis, or periarteritis nodosa</td>
</tr>
<tr>
<td>Staghorn (XR)</td>
<td>Branching radiopaque densities following the outline of the renal pelvis</td>
<td>Renal calculus that fills the entire renal collecting system, forming a cast of the renal pelvis</td>
</tr>
<tr>
<td>Stipple sign (Angio)</td>
<td>Contrast material trapped between the papillary projections of urothelial cell carcinoma</td>
<td>Urothelial cell carcinoma, best seen in large papillary bladder tumors</td>
</tr>
<tr>
<td>String of pearls (Angio)</td>
<td>Arteries with thickened ridges, alternating with wall thinning and aneurysm formation</td>
<td>Fibromuscular dysplasia</td>
</tr>
<tr>
<td>Thimble bladder</td>
<td>Thick wall of calcification in the bladder that reduces its capacity</td>
<td>Tuberculosis of the bladder</td>
</tr>
<tr>
<td>Threads and streaks sign (Angio, CT, MR)</td>
<td>Linear string/thread-like vessels supplying the intravascular tumor in the affected vasculature</td>
<td>Vascularized tumor thrombus extending into the renal vein or IVC</td>
</tr>
<tr>
<td>Toy jacks (XR)</td>
<td>Spiked density in the urinary system</td>
<td>Calcium oxalate diphylate stone</td>
</tr>
<tr>
<td>Tramline or railroad track calcifications</td>
<td>Thin rims of dystrophic calcifications on both sides of renal cortex</td>
<td>Renal cortical necrosis (most commonly). Glomerulonephritis, hyperparathyroidism, Aport syndrome (less common)</td>
</tr>
</tbody>
</table>

Angio, angiography; CT, computed tomography; MR, magnetic resonance imaging; XR, plain x-ray; IVP or retrograde pyelogram.

Voiding Diary

(See also Section II: “Voiding Diary (Frequency Volume Chart (FVC)).” This form is meant to be completed by the patient.)

This voiding diary records your amount of fluid intake, amount you void and if there is any leakage of urine. It should be completed for an entire 24-hr period. For the most useful results, it should be done over 2 or 3 separate 24-hr periods. You must measure and complete this form every time you void or experience urinary leakage. Please bring these voiding diary records to your next Urology office visit. Copy additional pages if needed.

How to complete this form:
1. Begin the record with your first morning void after you wake up for the day.
2. Measure all fluid intake and the amount voided in mL or ounces. Ladies can measure the amount of urine by placing a plastic bowl or collection container that we can provide to you on the toilet seat. Men can void into a suitable collection jar or other container.
3. If you experience sudden leakage of urine, note the activity you were doing at the time of leakage (laughing, coughing, sneezing, lifting, etc.).
4. If you experience urinary leakage, use the following scale to estimate the amount of urine that you leaked:
   1 = Dampness
   2 = Wet underwear or pad
   3 = Soaked through or emptied bladder
5. Indicate by Yes/No if when you leaked you had an urge to void. FVC
